How to Build and Tune Antennas
Work more DX with the right antenna for your location. New book gives step-by-step instructions (176 pages, 200 illustrations) for building every type of antenna: long wires, dipoles, yagis, trap, etc. Plus many others not described elsewhere: low cost miniature beams from converted TV antennas, indoor beams, "invisible" antennas; window sill antennas, 40 meter beams, vertical beams, Novice Band DX, many, many others. Secrets of tune-up of both manufactured and homemade antennas for greater DX. How to use antenna test gear. Buy book "Ham Antenna Construction Projects" at your "H.W. Sams" distributor. Only $3.95. Or for autographed copy, send $1.00 (cash, ck, or m.o.) direct to author, J.A. Stanley, 855 South Fillmore Street, Denver, Colorado 80209. Pay postman balance COD plus postage. Or send full amount for post paid delivery. Money-back guarantee.

timer and the patch-off relay momentarily interrupt the power to the patch-on relay, again deenergizing the relay. The switching relay is operated by the carrier-operated relay in the receiver.

When no carrier is coming into the repeater, one set of contacts holds the transmitter keyed on while a second set of contacts connects the audio from the telephone line to the transmitter. A transmission by a mobile unit operates the carrier-operated relay in the repeater, which in turn operates the switching relay in the patch. When the switching relay operates, the telephone line is switched from the transmitter input to the receiver output. The contacts used to hold the transmitter on are opened and allow the telephone patch to be used in two ways.

If the patch-on relay is wired to disable the normal repeater keying circuit, the telephone patch operates in a semiprivate mode. The conversation from the telephone to the mobile goes out on the channel, but when the mobile transmits, the repeater transmitter goes off the air (not shown on the diagram). The way we normally use the patch, the carrier-operated relay keys the transmitter in the normal way and both sides of the telephone conversation are transmitted over the repeater channel. Since the "pulsing relay" is open at any time tone is being transmitted, practically no tone is ever transmitted over the telephone line.

Both the channel A and channel B repeaters are General Electric Progress Line repeaters, and are equipped for 600Ω audio input and output. Our phone patch transformer is a salvaged telephone company one-to-one repeat coil obtained from the local surplus emporium.

System Levels

Overall system performance will depend on how carefully everything is set up in the first place. The Wichita repeaters are both wideband. We limit audio levels to 12 kHz for the mobile units. By setting the transmitted tone levels to 9–10 kHz, we do not have chopping to contend with, and the decoders work reliably even when the voice audio is just barely understandable. In most cases, the audio becomes too poor for phone patch quality before the decoder reliability enters the picture. Keep in mind that hard limiting or volume compression will degrade the performance of the decoders. It is extremely helpful if a signal generator with external FM capability is available for testing the system. We have verified that the system is erratic at the 5 kHz deviation level, and is very reliable at any deviation level above 6.5 kHz.

2805 Hz filter

We retransmit the tone through the repeater as we plan to locate muted monitor receivers in various locations to alert needed persons in emergencies. Regular listeners who do not like to hear the tone can use simple filters such as the one shown in Fig. 7 to virtually eliminate the tone. Insertion loss is less than 3.0 dB, with tone attenuation well over 20 dB. We use two of the filters – one at the input to the first audio amplifier stage, and one at the input to the second audio amplifier stage. We use the 88 mH toroids tuned to 2805 Hz with a capacitor and a balance potentiometer. Adjust the potentiometer for the deepest null while checking that the frequency is correct by slight variation of your audio generator frequency. Replace the potentiometer with a fixed resistor and install in your receiver. Possibly higher- or lower-inductance coils would work better – we haven't tried since these are satisfactory.

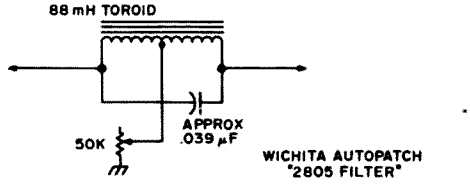

Fig. 7. Toroids can be used as 2805 Hz filters to remove unwanted tone signals from receivers.

Negotiating Permission to Interconnect

This system requires a telephone line or interface at the repeater site. (In the case

SOUTHWESTERN BELL TELEPHONE COMPANY

Wichita, Kansas 67203

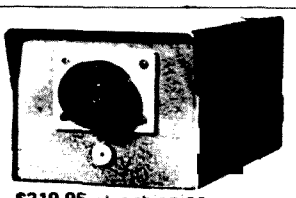
Dear Clem,

In answer to your letter of November 10, we have received approval to provide the automatic radio-telephone interconnect. This arrangement is allowable if we provide a standard Automatic Connecting Unit and if the network access line is the rotary dial type.

We do not have a tariff filing for this arrangement; however, it can be provided through a Special Assembly of Equipment rate. This rate will be $7.25 monthly and an installation charge of $20.00 will apply. This service can be provided within 30 days from the placing of an order.

If I can help in arranging for this service, please call me at 268-1376.

Sincerely,



Gerald W. Knox
Special Representative

Fig. 8. Letter from Bell granting permission to connect a "foreign attachment" to telephone line. Note that Bell provides the interface connection — for a fee.

of a split location, it will work at either one.) I made verbal and written inquiries, but for a long time I received no answers. As time dragged on, I made a direct connection to the telephone line, expecting to goad the telephone company into saying yes or no. After several weeks of operation, the Sedgwick County Civil Defense Radio Officer, Clem Sawyer (KØYER), and I mounted a new attack using Civil Defense prestige as a lever. It took six weeks to obtain the permission we sought (Fig. 8). If you wish to connect directly to the telephone line without the telephone company interface equipment, connect the *off-hook* and the *telephone audio* lines in series, connect to L1 and L2 inside the telephone instrument.

Summation and Afterthoughts

Detailed theory of digital pulse encoders and decoders is out of place in this article. Repeater groups wishing to build similar facilities into their repeater should try to locate a friend in the two-way radio business who services this type of equipment. Information on setting codes, multifunction decoders and simple explanations of how the equipment works can be found in the instruction books for General

DUAL GATE MOSFET
PRE-AMPS

to 175 MHz. $21.95 ppd.
to 300 MHz. $25.95 ppd.

NEW FOR 1970!
The above models now have rf gain control.
For 300 to 470 MHz
See Model 202 in our catalog.

- Available from 5 MHz. to 450 MHz. Bandwidth is approximately 3% of frequency.
- Voltage gain 30 to 40 DB depending on frequency.
- Two Dual Gate MOSFET amplifier stages with each having a tuned input and tuned output. Each Dual Gate MOSFET is actually an integrated cascode circuit thus giving you 2 cascode circuits equivalent to 4 triodes.
- Exceptionally low noise (2.5 DB at 175MHz.), greatly reduced cross modulation and 10 times the dynamic range (signal handling capability) of the best bi-polar transistors. Also superior to preamps using junction FETs and Single Gate MOSFETs.
- Internal connections for high impedance AGO or manual gain control if needed.
- Type BNC input and output receptacles for minimum loss at UHF. Standard impedance is 50-75 ohms.
- Carefully tuned at our laboratory with sweep generator and oscilloscope for the best bandpass characteristic.
- Full wave UHF diodes protect input transistor.
- Operates on 6 to 16 volts DC, 5 to 15 Ma.

New York City and State residents add local sales tax.

BACK ISSUE GUNSMOKE !

30, count 'em 30, stupendous tremendous (more handbooks than magazines) fascinating enormous devastating incredibly enervating back issues of 73.....

ONLY $5.00
postpaid worldwide

Yes...yes...yes...here is a golden opportunity to blow your mind on 30 back issues of 73. You send us $5 in negotiable securities, cash or check and we will send you an unbelievable miscellany of thirty different (all different) back issues, all from the 1960-1966 era. These are all rare collectors items. Every one could likely be worth a fortune to you. Who knows, you might even find a rare January 1961 in this pile! We don't even know what is in these packages. To keep costs down we have had these magazines packed into sloppy bundles by the Chimps from Benson's Wild Animal Farm (nearby). Watch out for banana skins. —If you want specific issues of 73 they are available at the low low (high) price of $1 each. Unless we don't have them, in which case the price is higher. —How about sending a bundle to a DX friend? Back issues of 73 are worth their weight in unicorn dung in most countries. —Money received without a shipping address will be used for beer.

73 Magazine Peterborough NH 03458

Electric EJ-18A,B,C, and D digital tone decoders, (all solid-state, no relays) and Secode Corporation SD-30 and SD-40 (also solid-state). The General Electric "Datafile" has several folders on Secode encoders and decoders. Local sales and service outlets for Secode Corporation can obtain information for you regarding single and multifunction models of their RPD-673 (12V, for mobile use) and RPD-674 (117V, for station use). Similar types of encoders and decoders are available from Scantlin, among others. Now that a large number of Wichita area amateurs are equipping themselves with the necessary encoders, we are adding features like selectable loose or tight squelch settings, tone key to energize the repeater during skip conditions or temperature inversions (normally the repeaters are to be carrier-energized, but during mild band openings things get hectic), and many others. We may be wiring up more selectors any day now. Transient 2 meter mobiles are welcome to use our autopatch facilities, but they must request the current on and off codes and meet the specifications as given in this article.

London's Science Museum Demonstration Station

Mosley beam antenna (TA36-40) on the roof of the Science Museum. Photo from the Science Museum, London.

Few hams can boast of a shack about 35 x 35 feet, two stories high, packed with equipment, most of it lent or donated, and logging between five and ten thousand contacts a year.

In London, England, though, the Science Museum runs just such a station – GB2SM, operating from the second floor of the museum's rambling building in London's fashionable Kensington area.

GB2SM is on the air twice daily – at 11:30 a.m. and 4 p.m. London time (1030 and 1500 GMT) demonstrating the principles of radio communication to an often-eager crowd.

As the station's QSL cards indicate, GB2SM operates with a Mosley TA36–40 beam antenna (on 40, 20, 15, and 10 meters), and Collins KWM–2 SSB transceiver and 30L–1 (500 watt PEP) linear amplifier. Three receivers are in use, and their signals can be put out through two large ceiling speakers.

Part of the main console of GB2SM, the Science Museum demonstration in London.

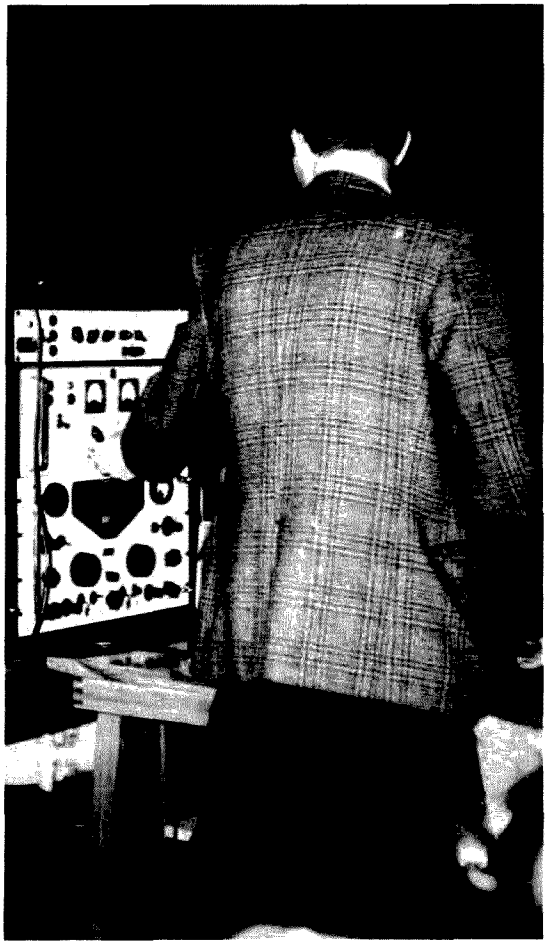
The station exchanges more than 3000 QSL cards annually.

GB2SM is not strictly an amateur station, as its somewhat unusual call sign indicates. Technically, the operation is a "demonstration station." Call signs in Britain beginning with GB are normally reserved for things like radio shows or conventions, and then on a temporary basis. The museum station is the only one in Britain with a permanent GB call.

Operations were started in August, 1955, to provide a means of getting young people interested in radio communication. Many of the more than 2 million annual visitors to the museum are under 21, and a good proportion of these can be found standing, fascinated, listening to conversation between GB2SM and other parts of the world.

"We know of quite a few young people," says the museum official in charge of the station, "who now hold licenses, and who tell us that their interest was first awakened here." To which staff operator Geoff Voller adds, "I worked a man some time ago who told me that he'd been waiting for a contact with us for years. He said he first got interested in ham radio here and had wanted the contact ever since he got his license."

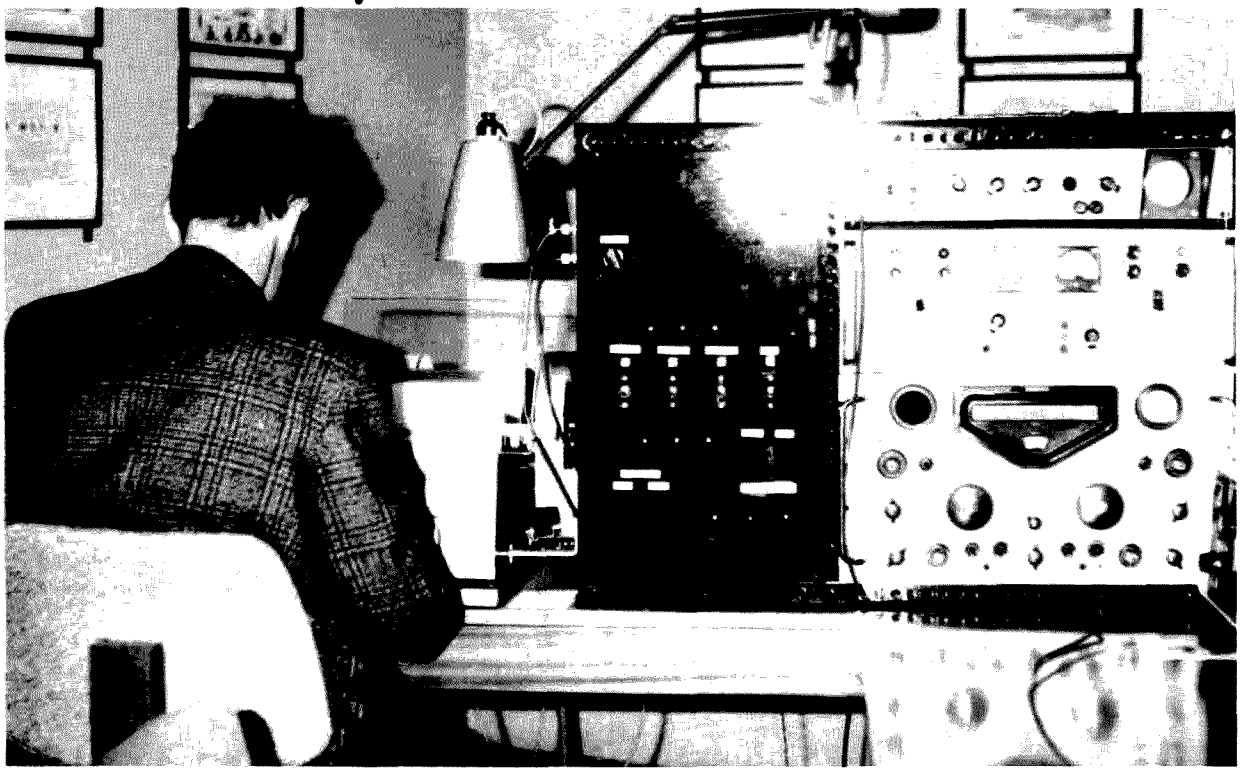
Voller, a full-time museum staff member, and himself a licensed amateur (G3JUL) runs many of the museum's ham demonstrations. On weekends, and on holidays and vacations, he is assisted by a small group of specially invited British amateurs. Because of the "demonstration station" status of GB2SM, all use the station call sign when operating, never their own call letters.



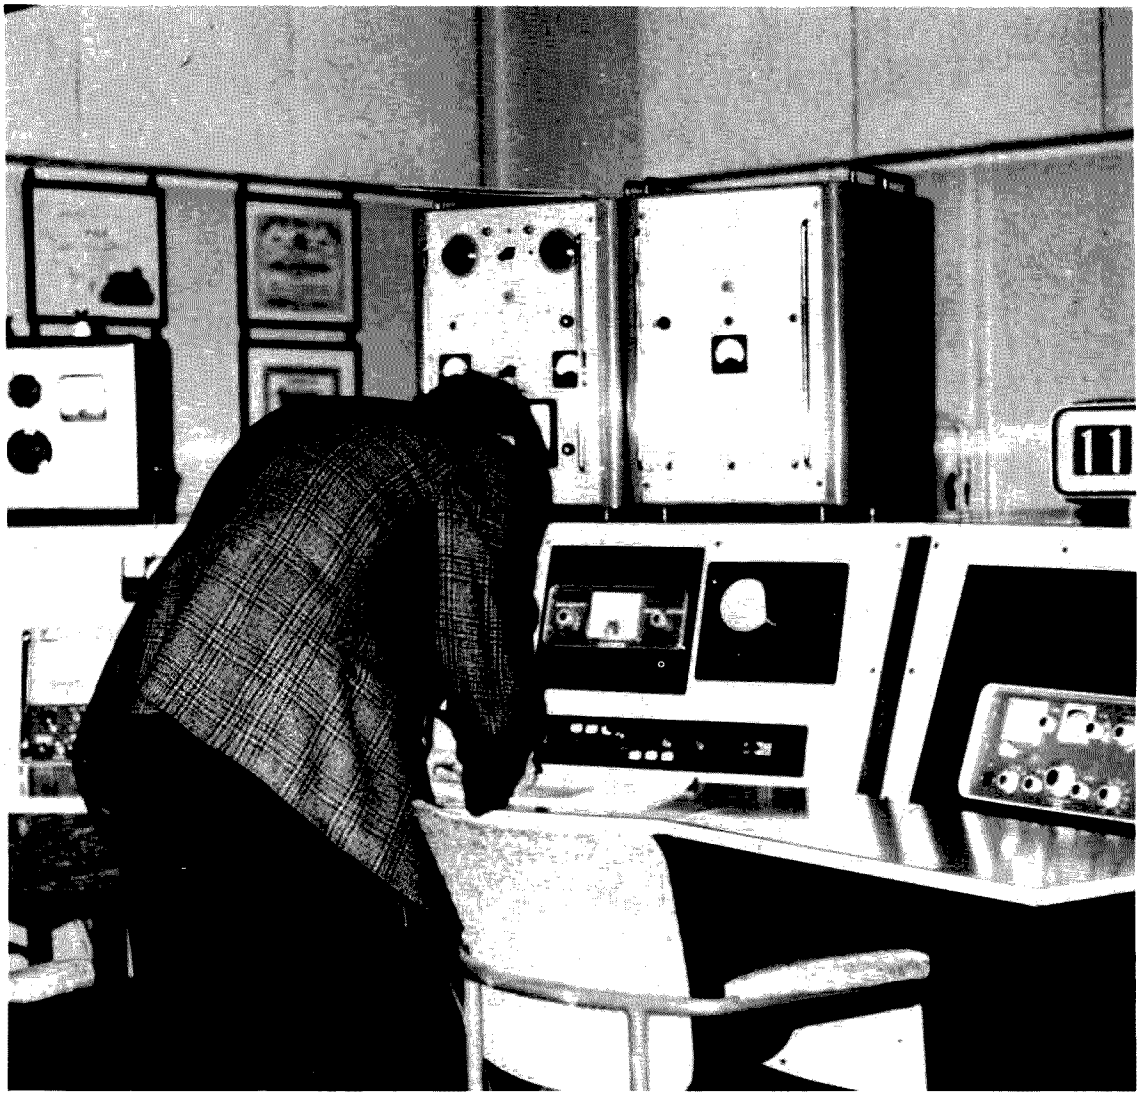
GB2SM maintains regular contacts with several parts of the world; a schedule with ZD9BM in lonely Tristan da Cunha is probably the most interesting of these. The museum station has occasionally proved a valuable auxiliary communications link during emergencies in Tristan.

During a recent morning demonstration, a contact attempt with ZD9BM was unsuccessful. In short order, however, the station logged QSOs with 9VØPA in Singapore and

with WA8RIS in Cleveland, who was calling CQ at the time. A brief contact with WAØITW (also CQ), and with OK2PJ in Czechoslovakia completed the half-hour operation.



Another morning Voller was "talking" with a friend in Holland via teleprinter, a form of amateur communication much more common in Europe than here. GB2SM maintains a teleprinter schedule with PE2EVO, a demonstration station in Eindhoven, Holland, home of the giant Philips electric firm.



The Science Museum's shack has walls covered with awards. The station enters about two contests a year, each of which requires a high degree of organization and logistic support ("we have to make all kinds of special arrangements to get people into the closed museum at 2 a.m. Sunday – that sort of thing – and keep an urn on the boil somewhere all weekend," says one museum official).

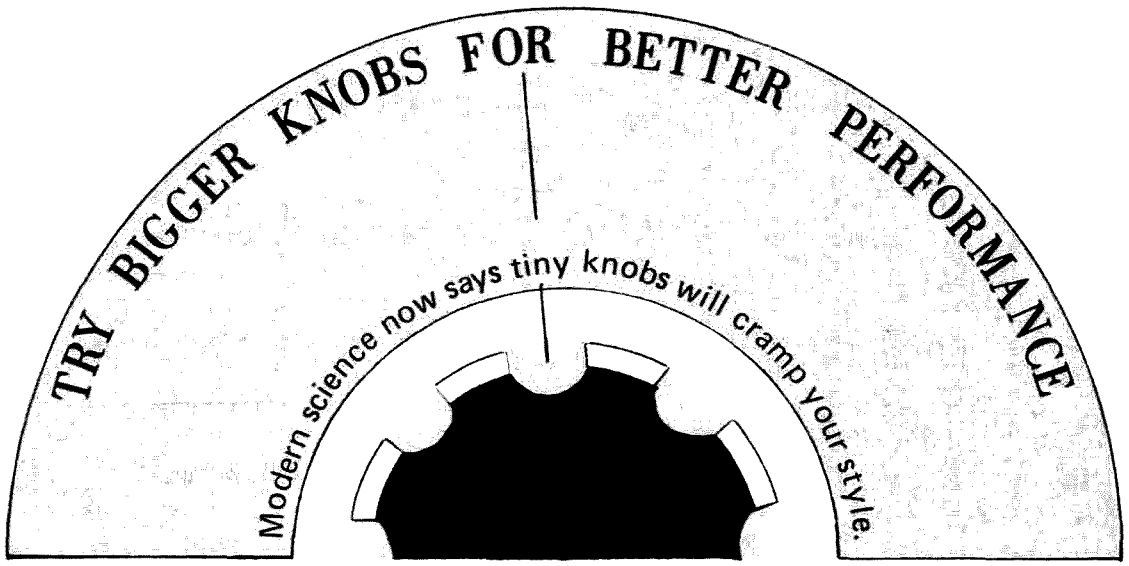
The museum's ham operator, Geoff Voller, adjusts teleprinter equipment during a contact with PE2EVO, in Eindhoven, Holland.

Geoff Voller at work on his teleprinter during "conversation" with Holland. Note awards on the walls.

GB2SM, London, at work. Operator Geoff Voller makes log entries at the conclusion of a half-hour demonstration. Station operates at 1030 and 1500 GMT daily, demonstrating principles of radio communication for a crowd in the Science Museum.

Despite the logistics, GB2SM has more than its share of awards. It boasts such citations as the Keystone award from the Harrisburg, Pennsylvania Radio Club, for being "the first station in England" to work more than 100 hams in Pennsylvania; the ARRL DX Century Club award, and the League's WAS award.

The Radio Society of Great Britain has given the station its "Empire DX Award" for contacts with 50 dominions and colonial areas on 14 MHz, and 50 additional contacts on the remaining bands.



Although the station can operate with code, voice, or teleprinter, most contacts are made with voice because they are the most meaningful to the ever-present audience.

Amateurs visiting Britain are invited to stop in the Science Museum to see the station at work. Its operators rarely see in person any of their thousands of contacts, and are glad of the chance to do so.

There is one restriction, though. GB2SM is not a "public" station, and is not open for use by any visiting amateur. You are most welcome, but the rule must be "please look, but please don't expect to operate."

Hardly an issue of 73 goes by without some articles devoted to miniature equipment. Test equipment, receivers, and even transmitters are rapidly going the miniature route. Smaller and compact rigs have much to offer, of course – not only in terms of reliability, stability, and instant warmup because of solid state design, but because they take up less space in the shack.

Yet, for some time I have found an irritating fault with miniature equipment. Indeed, it even goes to standard size equipment. Call it instead an annoyance, or a discomfort. My complaint? Operating knobs are just too small to be comfortably manipulated with efficiency.

I much prefer large, massive knobs on all my gear – whether they be on my tube-type receiver and transmitter or on that little solid state, homebrew transistor checker I often use. So where I can, I install knobs to about twice conventional size.

It's true that some manufacturers (like Hallicrafters, National, and Heath) generally use large knobs (about 1 in. diameter or more) on functions other than the main tuning dial. But most don't. Look at the new lines of transceivers and you'll see what we mean. Most come equipped with tiny, delicate knobs, seemingly designed for a feminine touch.

I'm not much of a contest buff, but if I were, I could offer a couple of strong reasons for large operating knobs. For one thing, larger knobs would eliminate groping, fumbling, or accidental manipulation of the wrong function during hectic QSOs. For another, they would allow you to make critical adjustments with ease (the turns ratio would be in your favor).

Why, then, the trend to small knobs? A hasty conclusion might be the limiting factor of the equipment's basic size. But upon looking over many catalogs and advertisements, you'll find that this just isn't the case. There is usually more than adequate space to double present knob size. So we can conclude that size of rig is generally not a factor.

One valid consideration might be cost. But here again, a check in the current

Lafayette catalog shows the difference between a ¾ in. plastic knob and a 1 in. knob of the same material and design to be a mere 3¢. Fluted knobs, commonly found on most commercial rigs and some well-designed homebrew rigs, have a price span of 4 to 5¢, from the smallest to the largest diameters. So the cost differential that we're talking about is really negligible.

On the face of it, then, there appears to be no meaningful justification for tiny operating knobs. Therefore, if you feel as we do, you can modify your present equipment with larger knobs at a nominal cost. And as for homebrew jobs, there isn't any sound reason for going the miniature route all the way.

At this point you're probably thinking that this entire business of optimum knob size (and shape) is not nearly as important and meaningful as I've indicated. But it is – and here's why:

The space age has ushered in a whole new science called "human engineering" that deals with this very subject. Believe it or not, there are hundreds of engineers around the country who devote their entire time to such things as scientifically determining what size knob, dial, toggle switch, lever, pedal, etc., is best, what material and color it should be, and where it should be best located on a particular piece of equipment. The findings of human engineering have been so revealing to space technologists that even industry is beginning to take a hard look at these results – all in the interest of getting maximum production from machines. The whole idea is to make manipulation of controls as easy and as effortless as possible for humans that have to operate machines of any kind. In other words, it is a science devoted to lessening human fatigue and thus optimizing production.

The implications of human engineering to amateur radio are obvious. The amateur fraternity is always striving to improve, update, and streamline equipment with a view to improving operating conditions. The technical articles in the various ham magazines attest to this. So it appears that knob size is one detail that serious amateurs should not overlook.

An important question to ask at this point, then, is: What is the best knob size? Has human engineering made studies in this area? Have conclusions been reached?

Since an operating knob is basic to virtually all electronic gear, one can rightfully conclude that studies in this direction have, indeed, been made. The findings are particularly interesting and support the author's view that knobs for amateur gear are – in the main – too small.

The August 1969 issue of Human Factors magazine contained an article by J. V. Bradley on "Optimum Knob Diameter." Essentially, Mr. Bradley stated that when frictional resistance is heavy, the best knob diameter is about 2 in. Actually, he described a range of diameters (relating turning time to knob diameter) for such applications to be between 1¾ and 2 in. Anything over and under these diameters is "significantly inferior." What constitutes heavy frictional resistance is something else again. But if we were to classify main tuning dials on receivers and vfo's as those having heavy frictional resistance, then it would appear that both homebrew and commercial rigs adequately meet these specifications.

But Mr. Bradley's article goes on to say that when frictional resistance is reduced to a minimum level, specifications change. Here, human engineering recommends diameters from 1 to 3¼ in. Bradley concludes by saying that these findings are valid over a wide range of rotary inertias.

It isn't often you see rf gain, audio, bandswitching, bfo tuning, or final tuning controls that meet this lower tolerance limit. At one time, when receivers and transmitters came in large packages, they did. But nowadays they rarely do, especially transceivers. Result: smaller knobs and dials.

The next time you put together a homebrew rig of any kind, give some serious thought to large knobs and see if you don't feel a bit more comfortable with them. Or better yet, try installing larger knobs on those appliances you have now. You'll see what we mean.

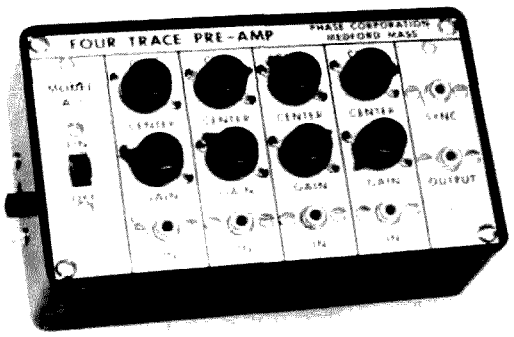
NEW PRODUCTS

Low-Cost Function Generator

Phase Corporation is marketing, as a kit or wired and tested, its low-cost solid-state test oscillator, which generates square waves, pulses, or sawtooth waveforms from 0.1 Hz to 100 kHz. Portable and compact, the package contains FET and unijunction circuitry to cover the operating spectrum in six continuous ranges. In the kit form, which sells for $34.95, all parts are included: transistors, diodes, switches, etched and drilled printed-circuit board, custom cabinet with screened and punched



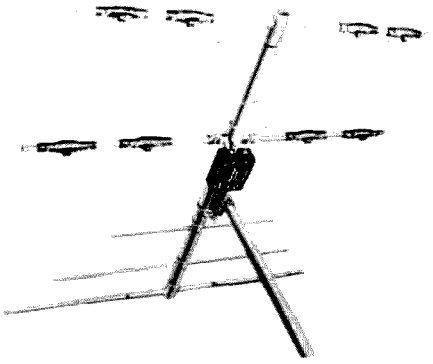
front panel, and easy-to-follow assembly instructions. The Model 01K designates the kit; 01W is the completed package, which sells for $54.95. (Both prices include postage within the continental United States.) Specifications for the Model 01 test oscillator are as follows:

Output 8V p-p, all ranges
Output Z 5 kΩ
Freq.
Sawtooth and pulse: 0.1–100,000 Hz
Square: 0.05–50,000 Hz
Risetime
Square and pulse: 0.5 μsec
Pulsewidth
1 μsec at 100 kHz
5 msec at 2.5 sec/Hz

Phase Corp. is located at *315A Boston Ave., Medford, Mass. 02155.*

Four-Trace Oscilloscope Preamp

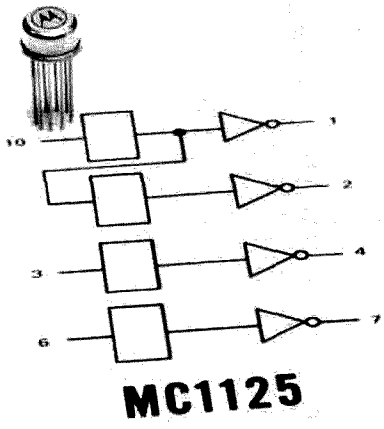
A four-trace oscilloscope preamplifier, the first in a new line of kits, has been announced by the *Phase Corp.* The preamp is designed for use with any ac or dc oscilloscope, providing the capability of observing as many as four waveforms simultaneously. Individual centering control is provided for each of the four inputs to the preamp. With an input impedance of 1 megohm/channel, the sen-



sitivity of the preamp is limited only by the sensitivity of the scope with which it is used. The preamp is compact, facilitating mounting inside the scope housing or in an optional case. The circuit of the preamplifier employs four FETs and nine silicon transistors. Included in the kit is a printed circuit board that comes etched and drilled.

Phase Corp., 315A Boston Ave., Medford, Mass. 02155.

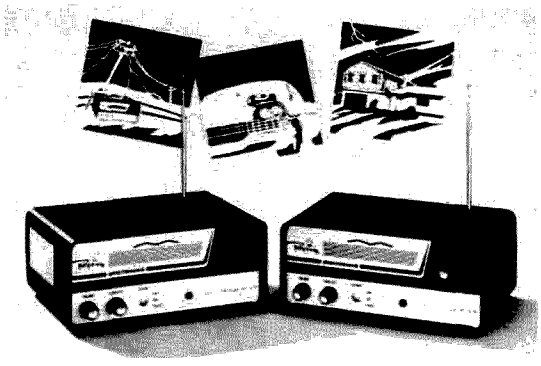
Challenger Beams Are Design Innovation



The Challenger line of antenna systems feature a balun-fed, 5-element Tri-Band array for operation on 10, 15, and 20 meters using a single transmission line. It has a peak power rating of 1 kW and a 28 dB front-to-back ratio.

Other Challenger models range from 3/4 through 80 meters. The entire line, as well as other Telrex antenna systems, are described in Catalog PL70 which is obtained free by writing to *Telrex Labs, Asbury Park, N. J. 07712.*

Monolithic Synthesizer MOS

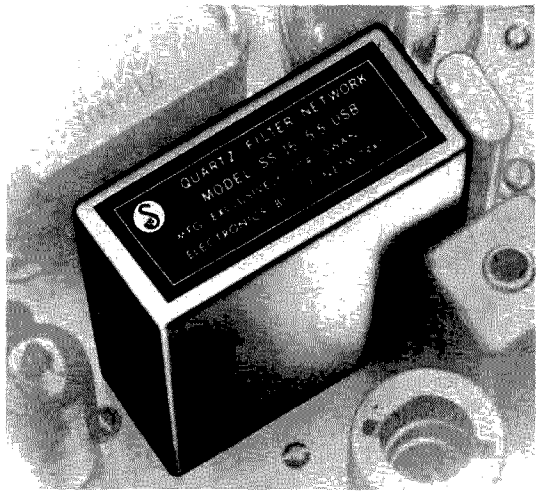


Motorola's MC1125G is a monolithic, quad MOS device consisting of four toggle-mode flip-flops with buffered Q outputs that use no standby power when driving capacitively coupled loads. Typical power dissipation is a low 75 mW and operation is from dc to 1 MHz. The MC1125G also

features a typical input capacitance of 2.5 pF and a crosstalk figure under 1%. The MC1125G is recommended for frequency synthesis, as required in organ circuits, digital dividers, and counters. *Motorola Semiconductor Products Inc., PO Box 20912, Phoenix AZ 85036.*

FM Receivers Have Built-in Decoder

Two FM receivers for operation in the 50 and 144 MHz bands feature a complete assortment of optional equipment, including a sequential tone alarm decoding facility. The radios are available in four model designations. Model TM II-H1 has a single-channel, narrowband reception capability in the 144–172 MHz band. TM II-L1 is the same for operation in the 30–50 MHz range. List price for both models has been set at $115.00, including crystal. Models TM II-H2 and L2 feature 6-channel reception capability in the respective fre-



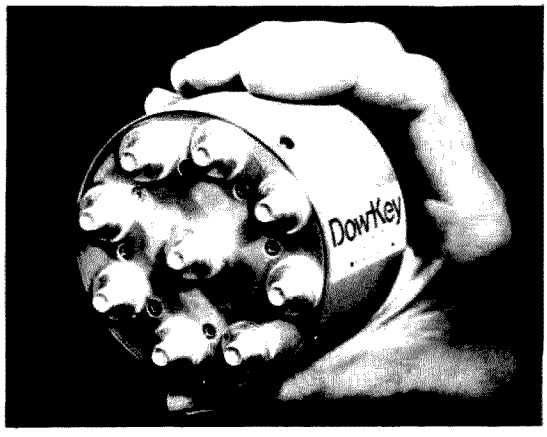
quency ranges at list price of $130.00, including 1 crystal. (Additional crystals are priced at $4.95 each.)

The receivers are being built as replacement units for the original TM series. New circuitry, however, enables the radios to deliver better performance without price increase.

Sensitivity for all models is rated at 0.5 μV. Selectivity is set at 50 dB at ±15 kHz. The receivers operate on 117V with accessories for 12V dc or internal ni-cad battery power supply. *Regency, 7900 Pendleton Pike, Indianapolis IN 46226.*

Quartz Filter Offers Super Selectivity

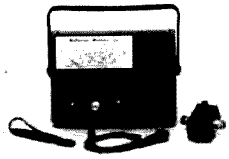
Made exclusively for Swan by CF Networks, an all-new 16-pole quartz filter network establishes a dramatic standard of comparison. Shape factor of 1.28, ultimate rejection greater than 140 dB! A giant QRM killer, the SS-16 wipes out strong adjacent channel interference with unprecedented attenuation. And in transmit



mode, unwanted sideband and carrier suppression are both increased greatly. Available only for Swan transceivers, they are made for the current 5.5 MHz i-f, or earlier 5.175 MHz i-f system. Installation and adjustment are simple. Specifications are as follows:

- 2.7 kHz bandwidth at 6 dB down.
- Shape factor 1.28.
- Ultimate rejection: 140 dB.
- 16 poles. 16 precision crystals in a lattice filter network.
- Sideband suppression: 80 dB.
- Carrier suppression: 45 dB with the filter alone, plus approximately 40 dB more from the balanced modulator.
- Mounting: Same as standard Swan filter, but taller.

Swan Electronics, 305 Airport Road, Oceanside CA 92054.



Remote-Controlled 8-Position Coaxial Switch

The Series 74 coaxial switch is intended for use in 50Ω circuits at frequencies up to 2 GHz, where the multiple sources are switched to a common output. To provide maximum isolation, all unused terminals of the new switch are

grounded. In standard configuration with type OSM connectors, the switch measures 3 in. diameter by approximately 2¼ in. deep. Other connectors available include types BNC, TNC, 27 series, and MB. The switch is normally supplied for operation at 26V dc. Other voltages available are 6, 12, and 120V dc. *Dow-Key Co., Box 348, Broomfield CO 80020.*

RF MULTIMETER, RFM-1

Simplifies construction and testing of solid state circuits, antennas and transmission systems.

Active Filter Features Low Power Consumption

A new hybrid active filter, the Model FS-60, requires only 0.3 mW of power at ±2V, making it particularly suitable for use in battery-operated equipment. The unit sells for $10 in large quantities. Operating in the frequency range from dc to 10 kHz, the FS-60 features multiloop negative feedback for high stability and a Q range from

0.1 to 500. Other key specifications include a voltage gain adjustable to 40 dB and the ability to attain complex zeros anywhere in the S-plane. Bandpass, highpass and lowpass outputs are available simultaneously. The filter employs encapsulated hybrid circuit construction and is housed in a 14-pin dual in-line package measuring 0.804 x 0.336 x 0.474 in. Complete specifications and additional pricing data are available from *Kinetic Technology, Inc., 3393 De La Cruz Boulevard, Santa Clara, Calif. 95051.*

Those DGP Maps

The three-dimensional maps that DGP Company is distributing make the normal topographical maps look like junky gas station maps. These not only are a great help to anyone working on VHF, they are about the last word in a fancy wall map. Businesses are grabbing these up for decorating their walls, they are going up on hamshack walls, and they are being used as gifts for sportsmen.

The detail on these maps is hard to believe. They get right down to even the little dirt roads! Each map covers an area about 100 miles by 70 miles and every mountain is clearly shown both with con-

Army Manual

The "Tech Manual" format for March is the best yet! Kudos to whoever thought that one up!

Fritz WB4MSJ

There were many comments from our ham-type technicians regarding your March issue on the front cover. All in all, they thought was a darn clever idea and they also made many nice comments regarding the quantity and quality of technical articles. I thought the amateur radio news page in the March issue was most interesting and I have removed these two pages and put them on the company bulletin board.

R.A. Kobold
Manager, Cust. Svc.

Re – the March issue – clever cover. The "NOT-TOO-TECHNICAL MANUAL" bit is especially right. Did you check pages 62 through 67? The guy (Bob Manning K1YSD) must be sick.

Everett G. Taylor W6DOR
4100 Worthington Dr.
North Highlands CA

Y?

A couple of things. First, as a professional communication engineer, I am enjoying those Extra Class articles. But tell me, what little gremlin, or type lice, made off with the letter Y in Table 1 on page 101 of the February issue???? Especially since RY is one of the favorite test letters on the circuits, along with the quick, brown fox.

Next, the February issue was delivered here in San Diego on 20 February, so those announcements of events happening before then were of only historical interest (whatever that may be). Looks like you should insist on a longer lead-time if the item is to be of value.

Les Harlow WB6ZNW
5015 Cape May Ave.
San Diego, California

My question is: Y?

You left it out of the RTTY list on page 101 of the February 1970, 73 Magazine.

And 'Y' is so important – it's the other half of 'RY' one of the most familiar terms in RTTY.

C.L. "Bob" Engelbrecht VO1BL
31 Cowan Avenue
St. John's, Newfoundland

Yoiks! Y is coded 1-3-5 and it most assuredly is one of the important letters for TT'ers.

. . . Wayne

League Representation

As a relative newcomer to amateur radio and a subscriber to your magazine I am only disappointed in one thing, that your magazine doesn't come more often. I feel as I'm sure most of your subscribers do, that you are the only ham amgazine which truly represents the amateur.

By all means amateur radio should have a lobby in Washington, if the ARRL doesn't push for a lobby we should ask who are they representing, amateur radio or their own little station in Conn. If the ARRL doesn't react on this it's time everyone reacted on them. I myself am not a member of the ARRL and do not intend to be until I feel they would be representing me and not their own interests.

As I have mentioned previously I am truly in love with your magazine. There has not been one article which I have left unread and undigested. It's truly worth every cent of it's price, even if you have raised the price. Now I'd like you to listen to one of my gripes. Even though I am a Novice I do spend most of my time scanning across the phone bands. And I must say I'm very disappointed with the general conversations. Now don't get me wrong – listening to a ham tell another how he gets such great modulation excites me just as must as the latest hit record, and I'll have some fish stories to tell too when I get my General, but is this all hams have to talk about? When is the last time you heard an on the air debate about the latest FCC proposal or some discussion over an amateur lobby? What I propose is this, a net be established to talk over these things, a place where some meaningful discussion might take place. 73 and other magazines might keep the net informed of latest developments and an FCC-net hotline might be established. Wayne and other writers might have some on-the-air editorials to promote discussion. Other subjects might be discussed which generally bring to harsh a reaction from the general ham population, such topics might include, SEX, RELIGION, and POLITICS. Anyone could therefore tune in on the net and find out what's happening on the amateur scene today. Some amateurs who don't subscribe to 73 aren't even in the right decade. I think that the net would be especially inspiring to SWLs contemplating becoming hams and Novices interested in becoming Generals.

Tim Rulon WN2KQD
12 Morahopa Rd.
Centerport NY

Urgently request your leadership in promotion of FM thruout amateur world. In my humble opinion FM has the potential to nullify CB, restoring Amateur Radio to its rightful place in public service. The excellence of FM as a communications mode for civil defense, etc. will bring about a revision of trends and policies,

If you don't feel that you got your money's worth—full return guaranteed.

3 DIFFERENT GROUPINGS TO CHOOSE FROM

GROUP A – **Actual Value $15.00 – PEP Price $1.25**

SAMPLE A-1: 200 diode – 7 transistors – over 50 resistors – complete with board.

SAMPLE A-2: Four I. C. Mounting Blocks – 3transistors – over 25 resistors – complete with board.

GROUP B – **Actual Value $20.00 – PEP Price $1.75**

SAMPLE B-1: 8 I. C. Mounting blocks – over 50 resistors – 32 transistors – over 30 diodes – complete with board.

SAMPLE B-2: 32 transistors – over 100 resistors – capacitors – over 15 diodes – complete with board.

GROUP C – **Actual Value $50.00 – PEP Price $4.50**

SAMPLE C-1: 22 in-line I.C.s – over 75 diodes – 20 trans. – over 50 resistors – capacitors – complete with board.

SAMPLE C-2: 22 in-line I.C.s over 50 diodes – over 50 resist – capacitors – complete with board.

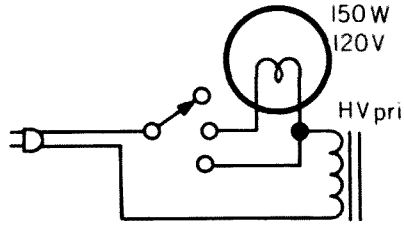
swinging public service back from CB to ham radio. Only hope the League isn't too blind to see this obvious fact nor too set in their ways to realize FM's potential to rescue amateur radio. I am confident in you and your staff to provide interim leadership and technical information until Newington's Ponderous Pachyderm starts to move. Can anything kill their apathy?

M.N. DeBlasio WA2HCD

We agree that FM has the potential to nullify the inroads made on public service by CB – which could prove highly beneficial to amateur radio.

. . . Ken

Big Brother



I wrote a letter to the League suggesting that instead of taking frequencies away from us, they should request the FCC to open new frequencies to us as an incentive. My reply from headquarters stated, in essence, that we should trust in the judgement of big brother in that they know what is best for us. Bully for them.

Earl WA1KYW

Arlington MA

Killing the Big Thump

For better than two years now I have been fooling with an 813 GG linear (two in parallel). It is built entirely of surplus *junk* (and I mean that in the strictest sense of the word!).

One of the biggest problems was the power supply which is made up of a 2500–0–2500 power transformer, 866 filament transformer, 1616 rectifiers (I used to have 866A's. . .they are directly interchangeable), and two *gigantic* oil-filled filter capacitors. With power supply turn-on I'd get the "big thump" and the most beautiful flash in the 1616s! It would then proceed to blow the 10A slo-blow's in the line plug *plus* the 20 amp circuit breaker in the shack!

I went through 6-866A's, and 4-1616's and kept thinking it was *scrounging* soft or bad rectifiers. The fact is, they couldn't handle the terrific surges!. I became aware of this fact after reading an article by R.T. Brackman and M. Weinschenker (73, Page 77, Jan, '70) on silicon rectifier diodes. I never realized there could be that much surge. In the Jan. '69 issue of 73 Mag. on page 22, W9VEY offered a solution. I didn't like this simply because I did't have a spare relay and the 20W, 5 kΩ resistor.

So. . .in my power supply I wired in permanently a 150W light bulb in series with one of the primaries. This is turned on first and then after a few seconds is shorted out to let the full 2500V in. This serves two purposes. . .one-it got rid of the "big thump" and the ensuing "big blow" by fuses, and two-I now have a 800V low voltage supply built in!

The light bulb is mounted in a plplug-in type light bulb socket so that if I have to change

bulbs, all I have to do is unscrew the old one and screw in the new one. It is mounted on a rotary switch.

Wayne Jinske WA9SSH
Custer WI

I wonder if it is not possible that Wayne's editorial stand concerning the League is not having some undesireable side effects.

Have you listened to W1AW code practice lately? Could it be that some of those who like to tune up on top of the code session or come slipping in from the Northeast over it might feel they are in their own way supporting Wayne in his battle with the league? I do not think 73 wants that sort of support. Perhaps these individuals do not listen to anyone or any publication. In any case I, in behalf of others who use the code practice service, would appreciate your help.

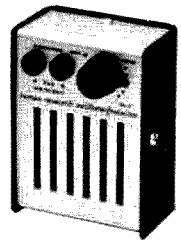
Bob Cutler WNØYED
Glenwood Springs CO

The FM Route

My wife and I just got back from a vacation trip of 2 weeks on the newest of highways: the new 146.34-146.94 open repeater FM highway.

I have been an amateur for many years, but never enjoyed anything as much as this trip on the highway open to the amateur today. As soon as we got 50 miles from Bloomington, Ill., I took the mike and said, "This is W9JFP/9 mobile." From there on, I had company all the way to California and back with the open repeaters on .34–.94 FM. Made hundreds of contacts – all so friendly I couldn't believe this was amateur radio. I was 60 miles from Tulsa and listening on .94 and a very pleasant voice broke squelch with: "This is WA5LVT, Tulsa Repeater; the time is 6:00 a.m." This was heard every ten minutes for the time I was in range, which was about 60 miles either side. Near San Diego I called but heard only a few stations and no responses, because this was an exclusive tone operated closed group; same story in Los Angeles, but on the way home, when we were 60 miles from Las Vegas, I got a reply from the open repeater in Las Vegas; and all the way back to Milwaukee, for 2200 miles of driving, I had company almost continuously thanks to my trusty 4Iv (which is old enough to retire) and the open repeaters on 146.34/146.94 FM. When we got within range of Chicago again in the exclusive area, couldn't make a contact because the repeaters were not open. All I can say is thanks to you and the 2 meter FM open repeaters.

Vic Weissbrodt W9JFP



The Chicago repeaters are open to transients, Vic. But the output there is 146.75 MHz because .94 is too active on a simplex basis. The stations you heard in San Diego were undoubtedly the same ones you heard in Los Angeles – Remotes Operated By Insociable Nets (or "Robin," as it's called in California.)

. . . Ken

FM Fringe Area

I have enjoyed your magazine ever since I started mooching off a local fellow ham. We have decided that I need my own subscription, especially since I tend to retain the FM articles, which I find excellent.

mark 2
oscillator/monitor

- makes an audible tone to monitor the RF of any CW transmitter from 10Mw to 1 Kw & 100Kc to 1000Mc, using only an 8" pickup antenna.
- can be self-triggered for code practice or the testing of solid state components and circuits.
- aids in tuning up & testing RF oscillator and power circuits.
- 4 transistor, 2 diode circuit, speaker, tone adjust, AA pencell, test tips, 8" ant., & magnetic base.
- cabinet is 16 gauge black & clear anodised aluminum, 3.4 x 2.3 x 1.2"
- US made & guaranteed for 1 year.

RG 196 AU 50 ohm teflon coaxial cable. Outside diameter .080" RF loss .29 db per foot at 400 Mhz. Silver plated shielding and conductor. Used for internal chassis wiring, antenna coupling, RF coupling between stages, etc. Random lengths from 35 foot to 150 foot. Colors: black, red, brown, blue, grey, orange. Regular price 23¢ per foot. Our price 5¢ per foot $3.00 per 100 ft.

455 Khz ceramic filters type BF-455-A. These filters will help to sharpen the selectivity of most sets using 455 Khz IF's. Use across cathode bias resistor in place of a capacitor, or in transistorized sets, across the emitter bias resistor. Impedance is 20 ohms at 455Khz., DC resistance is infinite. Impedance increases rapidly as you leave 455 Khz. Plan your own LC filter circuits at very low cost.
10 for $1.00 25 for $2.00

TOROID POWER TRANSFORMERS

T-2 This toroid was designed for use in a hybrid F.M. mobile unit, using a single 8647 tube in the RF amp. for 30 watts output. Schematic included. 12 VDC pri. using 2N1554's or equivalent. Sec. #1 500 volts DC out at 70 watts. Sec. #2 -65 volts DC bias. Sec. #3 1.2 volts AC for filament of 8647 tube. Sec. #4 C/T feed back winding for 2N1554's. 1¼" thick, 2¾" dia. $2.95 ea. -2 for $5.00
T-3 Has a powdered iron core and is built like a TV fly back transformer. Operates at about 800 CPS. 12V DC Pri. using 2N442's or equivalent. DC output of V/DBLR 475 volts 90 watts. C/T feed back winding for 2N442's. $2.95 ea. -2 for $5.00

TRANSFORMERS

P-7 117 VAC Pri. Sec. #1 185 VAC @ 120 ma. Sec. #2 6.3 VAC @ 4A. Double Half Shell Mail Box Type. SX 146 type. $2.75 ea. -2 for $5.00

Mid-Missouri is a fringe area of VHF, but it's coming along, especially on FM (146.94). Keep those VHF articles coming and congrats on a fine magazine; the March issue was beautiful!

Jos. McGrew III WAØZIK
Eldon MO

On Spectrum Utilization

I have just recently returned to stateside 40 meter operation and found the QRM level near that experienced overseas. So I would like to pass on to you my thoughts on the usage of amateur frequencies by broadcast stations. Here are two possible avenues of attack to remove some of the congestion from the air.

First and probably the most likely to show results in cost versus listener audience. I should think that the SWBC cost of transmission far exceeds the justification by number of listeners.

With the present budget cuts, the time seems right for amateurs to point out the cost of broadcast compared to that of amateur radio. On the transmitting end, broadcast is expensive and amateur radio costs practically nothing – and on the receiving end, SWLs pay nothing, while amateurs pay to be licensed.

Now the second course, by the very presence of broadcast stations in our bands, it would seem that they are not concerned by the interference we cause. When you consider the difference in power levels between amateur and government transmitters we can do them little harm; therefore, I suggest some joint frequency usage. In the 21 MHz band (above 21.450) hams could easily squeeze in contacts if cost reductions took some transmitters off the air and hams were allowed to fill in the gaps. I admit we would be competing with those who "come up on any clear freq" but we live with them now.

Stephen Miller WB6TVT (KA2SM)
San Diego CA

Dockets

The FCC has recently issued a notice of proposed rulemaking concerning, among other things, (1), Amateur radio license fees, and (2), VHF repeaters. I have the following objections:

(1) The increase in license fees would be in direct opposition to the Federal Government's anti-inflationary policy. An increase in fees to the suggested level would make the cost of a license prohibitive for many amateurs, and when the fees are further increased in the future, as would inevitably be the case, amateur radio might possibly become a thing of the past owing its demise to being "licensed right out of existence."

(2) Regarding the propositions to (a) eliminate crossband links on VHF repeaters, (b) confine the repeaters to specific segments of the 6 and 2 meter bands, and (c) limit the power output to 250 watts, I am in direct opposition to all three proposals. Since VHF repeaters are amateur stations licensed to amateurs as remote control transmitter locations, the proposals named above, (a), (b), and (c) are all in direct conflict with amateur licensing rules and operator privileges as stated in the FCC rules and regulations. Amateur operation is permitted on the bands according to the class of license held by the operator and method of modulation employed, NOT according to type of operation. This cannot be regulated in the proposed way

✶ A Gold-Mine for Antenna Installers!

Frequency Range: 40 to 230 and 470 to 860 Megahertz. Calibrated outword from 10 to 50,000 Microvolts. Nothing makes it easier to properly and speedily find the correct place to install TV, FM and Communication Antennas. You can measure and hear the signals with this 4½ volt battery economically powered unit. There is nothing else like it!

Only $120.00 FOB N. Y.

Liberty Electronics, Inc.
548 Broadway, New York, New York 10012, Phone 212-925-6000

unless the current rules and regulations concerning operator licensing and privileges are greatly altered. Hence, the proposals to confine VHF repeater operation to certain segments of the authorized bands and limit their power output is in direct violation of the current rules and regulations.

The proposal to eliminate crossband links on repeaters would greatly inhibit repeater activity and growth, and would make it impossible for many repeaters now present to continue operation. This provision also violates all previous FCC policy because crossband operation (AØ) is presently acceptable on all bands above 51 MHz according to the current rules and regulations.

The inhibiting of VHF repeater activity and future growth would present a great setback to emergency communication networks, and thus the FCC, by adopting these proposals, would be greatly reducing the ability of amateur radio to serve the public interests, which is also in obvious conflict with present FCC policy.

Thomas McLaughlin WB4NEX/9
N. Manchester IN

Open Letter to Hams Everywhere

Dockets 18802 and 18803 endanger the existance of amateur radio as we know it today. Individual and group action on these dockets can help, provided that both individuals and clubs respond in the form of comments to the FCC *and* cards and letters to congressmen and the White House.

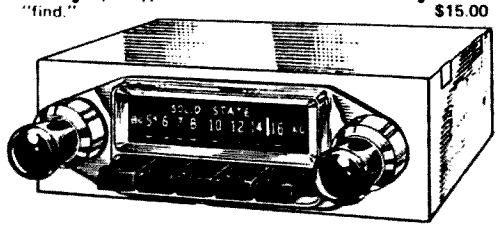
Note that the ARRL has not been a party to Docket 18803 other than to verbally support the Buffalo petition. Unfortunately, the only part of the Buffalo petition that filtered into Docket 18803 has to do with logging and tone access. ARRL is opposed to 18802 on grounds that the amateurs do most of the work in licensing and policing the bands themselves.

Three steps should be taken immediately...

1. Request an additional 30–60 days for reply comments on Docket 18803. The mechanics of obtaining comments filed – in order to file reply comments – requires more time for reply comment filing.
2. File individual and group comments on Docket 18802 as soon as possible.
3. Write to your Senator, Representative, and the President expressing your feelings on these dockets. (This pressure will also be felt back at FCC.)

Copies of comments should be retained for future use – it will do no harm to send a copy to ARRL also. In this way you let them know your stand.

Need a Xerox? FCC needs the original plus 14 copies of everything you send them. The New England FM Repeater Assn. will make copies of comments from individuals only – if the original is sent to us.



Gordon Pugh W1JTB

Two-Party System?

With advent of incentive licensing, I sort of lost interest in ham radio and let my subscriptions to the four mags lapse. Recently, I came across your Dec. '69 issue and after having read your remarks on the ARRL and reviewed the other material in it, my interest was stimulated to the extent that I am herewith renewing my subscription for three years. I would like to see

TRANSISTOR AUTO RADIOS

Brand new factory packed automobile radios, vintage around 1961. 12 volt neg. ground. No choice of models. The exceptional sensitivity of an auto radio makes it superior for use in car, boat, truck, camper, etc., where you are quite a distance from xmtr location. This is also the best kind of radio to use with short wave converters. Each with large original equipment hi-fi speaker. Some with noise suppressor kit. High quality, most made to sell in the $100 range. A real "find." $15.00

2 METER ARC-3

Just uncovered a batch of the famous ARC-3 rcvrs & xmtrs with all tubes. Range 100-156 mc, 8 xtl channels. Cheap way to get on 2 meters, CD nets, MARS nets, etc. With conversion details. Rcvr $15, Xmtr $15.

RF FERRITE CORE CHOKE

Hi-permeability, ultra midget style, coated for moisture resistance, color coded. Used in xmtrs, receivers, converters, TV-peaking. Brand new, worth 40¢ each. Assortment of 1.8, 27.0, 330 uh. Pack of 30, $12.00 value.

#A-71 30/$1.00 180/$5.00

TRANSISTOR MOUNTING PADS

Round fibre glass insulating pads, used under 3 legged TO-5, TO-18, etc. Raises and insulates transistors from PC board. Permits longer leads to be used with less danger of heat destruction. Adds professional touch to finished circuits. Bag of 50 pre-drilled pads.

#A-3 50/$1.00 300/$5.00

PHOTOFLASH TRIGGER XMFR

Thordarson #22R44 brand new, produces 15KV pulse. With spec. sheets.

#22R44 $1.75 each 10/$15.00

TRANSISTOR SOCKETS

Universal socket for 3 pin transistors. Bag of one dozen $1.00 Stock #S-1

Texas Inst. 10 or 14 lead flat pack socket for test or prototype work. Lists for $3.70 – Our price only $1.00 brand new.

TO-3 socket for power transistors made by AUGET. 6 for $1.00

BLEEDER RESISTOR

50K ohms, 100 watt ceramic $1.00 ea.

Above equipment on hand, ready to ship. Terms net cash, f.o.b. Lynn, Mass. Many other unusual pieces of military surplus electronic equipment are described in our catalog.

another group form similar to the ARRL, but with more progressive ideas and better representation of the amateur body. Certainly others in hamdom must entertain this idea. You have the vehicle in 73 to bring them together – why not do something in a positive direction about it? We have a two-party system in government – why not the same in ham radio?

Dick Dunn W1BPM

Wayne – In your article "ITU Conference: Who lobbies for Ham Radio?" I think you have made a statement that is in error. If I interpret it correctly, you say ARRL is a "tax-free" organization because it is a "non-profit" organization and you state that they cannot legally register a lobbyist to represent them with congress.

I base my reasoning that you are mistaken in this matter on the fact that the March 1970 issue of the American Rifleman, the Official Journal of the National Rifle Association of America, states that it "is an independent nonprofit organization supported by membership fees" and, in an article titled "A Statement" by the president of the National Rifle Association, it is stated that "We do have a representative registered under the Federal Lobbying Act for the purpose of necessary contacts on national legislation affecting the rights of gun owners."

Hence, Wayne, if it is legal for the NRA to have a lobbyist would it not also follow that it would be legal for ARRL to do likewise, if it wished to?

Clayton C. Gordon W1HRC
P.O. Box 85-West Main St.
West Millbury MA

Nonprofit does not mean tax-free. You will find that the NRA is not tax-free, that they are paying their way like any other business even though they are nonprofit. The ARRL saves thousands of dollars a year by being tax-free and this means that they cannot by law register as a lobbyist in Washington for amateur radio.

. . . Wayne

Democratic?

Would you perhaps like to mention in a future column that while ALL licensed amateurs are eligible for "FULL" membership in the ARRL, only those holding a general or higher class license are eligible to hold office. A quick look at the breakdown of licensees in the callbook will convince you that the ARRL is not by any meaning of the word a democratic organization. As a number two punch you might look into the awarding of the Ø QSL bureau. I understand that this situation stinks to high heaven too.

Col. D. Lester W1AER

The League system of government is comforting to those in charge and a frustration to any members who are concerned over League HQ actions. The March 1970 QST editorial tells members not to write to HQ, just to their directors, if they have a complaint. The feeling, right or wrong, is that writing to the director is futile since this "representative" appears at HQ but one or two days a year of highly structured routine meeting work. This means that the possibility of any individual being represented is virtually nil. The boss that comes to work one or two days a year has no real idea of how the business is really going, no idea of the competence of the employees, and no opportunity

whatever to hire and fire employees, no matter how bad things may get. The employees are the ones running the company in this situation, not the bosses (directors).

. . . Wayne

Printed Circuits

I have just finished reading with some interest the PCB article by Ken Sessions, and would like to pass along a few additional hints for the benefit of those readers who are not familiar with circuit board fabrication. I have used these methods both for "homebrew" projects and also for the building of several items which have flown in NASA sounding rockets and other space-qualified hardware, they have worked out quite successfully with high resolution boards. We have achieved, at best, conductor widths of .02" and spacings of .05" under conditions which most amateurs can duplicate using conventional photo methods. However, back to the hints for use with the Bishop system.

A "bug light" of 60 to 100 watts is quite satisfactory for a safe working light while working with sensitized boards, and gives quite adequate light levels.

A low-cost UV exposure light can be made from a desk-type fluorescent lamp by replacing the normal bulb with a "blacklight" lamp that emits light primarily in the violet and near-UV. Hope these additions to the info already given will be of use to someone wanting to turn out some home built gear. There are too few builders left on the ham bands.

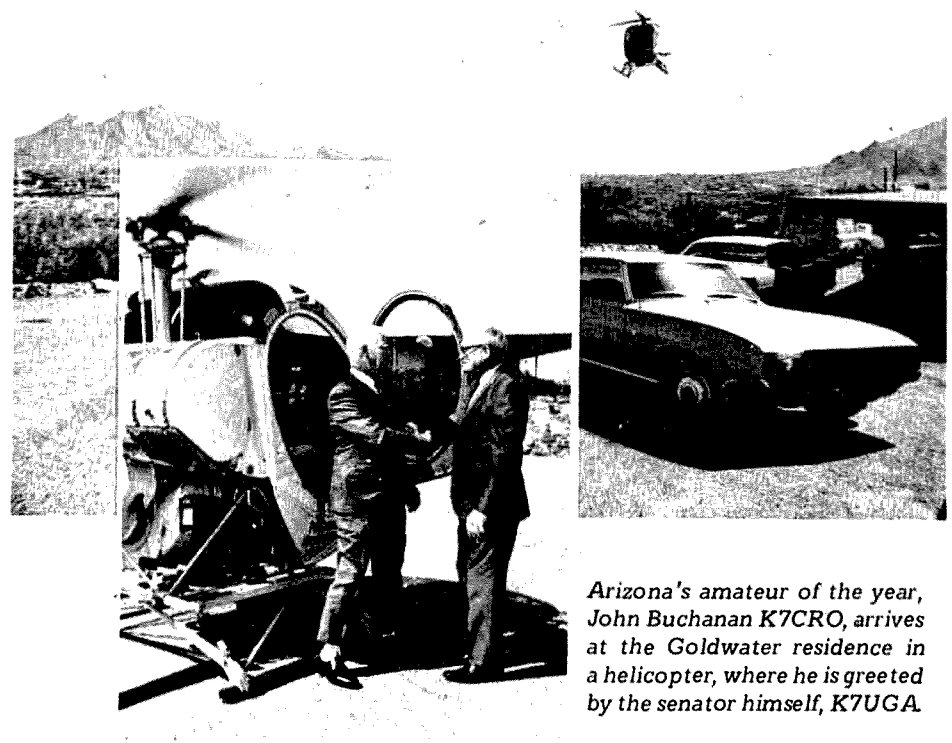
GOLDWATER PRESENTS HAM AWARD

Winner Flown to K7UGA Residence by Helicopter

by Bob Dreste K7VOR

Over the past seven or eight years, John Buchanan, a Tucson ham VHF-FM radio operator, has helped other amateurs repair their sets, taught them the tricks of the trade. He recently set up an amateur repeating station for FM at the top of Mt. Lemmon.



So when, for the first time, a state VHF-FM "Amateur of the Year Award" was given this year, it wasn't too surprising that Buchanan was the recipient.

He was flown by helicopter Thursday to the home of Sen. Barry Goldwater, in Phoenix, where he was presented a plaque for his research and activities in the VHF-FM ham frequencies.

More important, he was also given a solid state Varitronics IC2F, one of the newest instruments on the ham radio market.

The radio is symbolic, in a way, since Buchanan's latest project involved designing a new concept of a repeater station which would be all "solid state."

The concept itself is not new, Buchanan said, because it has been used for some time by commercial FM

Arizona's amateur of the year, John Buchanan K7CRO, arrives at the Goldwater residence in a helicopter, where he is greeted by the senator himself, K7UGA.

SPRING BRINGS RASH OF HAM TRAGEDIES

by W6KGN

In Costa Mesa, California, 20-year-old Laurence Bandiera (call not known) was electrocuted when the antenna he was erecting fell against a high-power line. Policemen who were called to the scene said that Bandiera's neighbor, Merrit Girgis, was helping with the antenna when it began to topple. Bandiera, Girgis told police, tried to hold the antenna as it fell against the wires. Attempts to revive Bandiera were futile.

Word-of-mouth reports from sales personnel at Radio Products Sales Co. in Los Angeles indicate that two other hams were killed in a Southern California plane crash. According to the source, the two were overflying hilly terrain in the vicinity of Los Angeles to look for a 2 meter FM repeater site. The two FM'ers were Carl Sundstrom K6IYI and Clarence Emerson K6QIP. Unconfirmed reports indicated the two were operating on 2 meters FM at the time of the crash.

Amateur Radio Station Operates At International Standards Meeting

stations, but ham radio operators are just beginning to get into the field of FM.

Up until now, he said, FM equipment was too complicated for the amateur to build. Recently, however, FM equipment has come on the market, either as obsolete or surplus goods, and the noncommercial radio operators are able to obtain what they need.

Buchanan has been in ham radio for about 12 years, but it is still just a side hobby. His business, logically, is machines, and he owns the Buchanan Machine Co., 2550 N. 14th Ave. in Tucson.

The honored FM'er displays bronze plaque and Varitronics newly released IC2F 2 meter FM unit. FM'ers will recognize Bill Adams K7OED president of Varitronics, Inc. on the right; ALL hams should recognize Barry Goldwater, who presented the award.

HAM RADIO in U.S.S.R.

by WB2CGE

The Soviet Union has some of the world's most skilled amateur radio operators and builders. Credit for this goes partly to the Soviet government, which sets high licensing standards and offers surplus equipment, technical knowledge, and attractive rewards as incentives. Possibly no other government does as much for its hams.

Despite these encouragements, almost no mass-produced equipment designed especially for Soviet amateurs is available. Today the Soviet Union's amateurs number over 15,000, second only to the United States' 300,000. About 10% of Soviet hams are women.

In order to become a licensed amateur, Russians usually follow this procedure:

1. Complete a basic electronics course.
2. Join a club and take a test which licenses them to listen on the ham bands. They must be able to send and receive code at 10 wpm.
3. After at least six months of experience as an SWL, the Russian applicant is then able to take the third class test.
4. The third class test consists of a more difficult exam and 12 wpm code test. The schematic of a 10-watt rig must be drawn, and they must explain how it would be integrated, how frequency stability would be achieved, what kind of antenna would be used, and how it would be tuned. The third class certificate permits them to use 10 watts on 3.5–3.65 and 7–7.1 MHz, CW, and 28–29.7 MHz phone. Licenses are renewed only when the operator moves to another class.
5. The second class license is more difficult. When passed, Russian hams are permitted to run a maximum of 40 watts. They can operate CW on 3.5–3.65, 7–7.1, 14–14.35, 21–21.45, 28–29.7, 144–146, and 420–435 MHz. They can use phone on 10 meter frequencies. 160 meters is not open to Soviet hams, nor is 6 meters (which is taken by TV).
6. The difficult first class exam is similar to the extra class in the U.S. They must be able to send and receive code at 18 wpm, design transmitter and receiver circuits, and build and troubleshoot advanced transmitters and receivers. They can run 200 watts CW or phone on all bands available to second class operators.

RADIO SHACK AND ALLIED JOIN

Form Multimillion Dollar Retail Merchandising Firm

Allied Radio, one of the most popular sources of ham gear in years past, has just been acquired by Tandy Corporation, parent firm of the multi-outlet "Radio Shack." The result is a total chain of more than 700 electronics department stores in 48 states.

To kick off the new association, all Radio Shack stores will display Allied catalogs. In time, the individual stores are expected to stock a large percentage of Allied's 30,000-item line.

For the time being, all Allied stores will continue to operate under the Allied name, though such stores will begin stocking Radio Shack's exclusive lines, such as *Realistic*, *Archer*, and others.

On the surface at least, this appears to add up to a pretty good deal for the amateur radio operator, who has never had much trouble finding a Radio Shack store, but who frequently finds it difficult to find the ham gear items he needs. With Allied's ham gear line, and Radio Shack's merchandising centers, getting parts and supplies should be simplified considerably in the future.

A special amateur radio station will be operating from the Washington Hilton Hotel in Washington, D.C. from May 17 to 30 while more than 1400 delegates from 41 countries are assembled there for the 35th General Meeting of the International Electrotechnical Commission.

Special temporary authority has been granted by the Federal Communications Commission to operate the amateur radio station which will have the callsign WF3IEC.

The station will be installed in Suite 9101 of the hotel. It will be under the supervision of amateur operator Ed Redington whose callsign is W4ZM. Mr. Redington will be assisted by members of the Foundation for Amateur Radio.

The station is planning to be on a round-the-clock basis. Single sideband radio-telephony and radio-telegraphy will be used on all bands except 160 meters.

A special acknowledgment (QSL) card will be sent to all who contact WF3IEC. Confirmation cards may be sent to W3ZA, L.M. Rundlett, Engineering Dept., Electronic Industries Assoc., 2001 Eye St., N.W. Washington, D.C.

The International Electrotechnical Commission is the oldest international standards organization in the world. The Commission is meeting in the United States for the first time since 1954.

FIELDDAY-CONTESTS

The German Amateur Radio Club invites amateurs from all over the world to participate in the German Fieldday-Contests 1970.

These contests are mainly for portable operating outside the home, independent of the mains using only batteries or petrol-electric generating sets for power supplies. For complete details contact Norbert Meyer DJ7JC, DARC Fieldday-Manager, POB 1752, D-463 Bochum, Germany.

Auction/Hamfest
in Pennsylvania

"Second Sunday in June," Third Annual Hamfest of the Foothills Radio Club, Inc., of Greensburg, Pa., will be held in Wendel Park, Wendel, Pa., 3½ miles South of U.S. Route 30, Irwin, Pa. All activities under an enclosed pavilion, rain or shine. Snack Bar for lunch, registration only required for prizes and parking is free. Drawings, displays and the traditional "trunk-line" merchants. New this year – public ham hear auction and a Club Display Contest."

QSO Party

The White Sands Amateur Radio Station, K5WSP, will hold a QSO party on July 9, 1970. The QSO party will be held in conjunction with an "Armed Forces Day" open house at White Sands. K5WSP will send a special commemorative QSL card to all stations contacted during the QSO party. The proofs of the QSL card are completed and the final, full color, model will be going to the printers soon. The card depicts 25 years of progress in aerospace and nuclear research and development at White Sands Missile Range. There will be several rigs operating simultaneously in the General class phone bands and possibly one Novice class band.

HAMFEST
Six Meter Club of Chicago Inc.

The Six Meter Club of Chicago, Inc., will hold its 13th annual hamfest in Frankfort, Illinois, on Route 45, one mile north of Route 30, on August 2, 1970. We anticipate that at least 1200 licensed amateurs, members of their families, and others who share an interest in amateur radio will be present. Contributions such as electronic parts, kits, components, books, QSL cards, antennas, magazines, instruments, gift certificates, etc., will be gratefully appreciated. All contributors

Pittsburgh, Pa.

The 16th annual Breeze Shooters Hamfest will be held at White Swan Park near Pittsburgh PA on May 17, 1970. This event attracts over 1200 amateurs annually. For more information contact J.L. Burnett K3IXB, 608 Charlotte Drive, Pittsburgh PA 15236.

ROME HAMFEST

The Rome Radio Club is holding its annual Ham Family Day on June 7, 1970 at Beck's Grove, Blossvale, New York. There will be three programs running simultaneously; one for hams . . .one for the ladies. . .and one for the children. The Hamfest starts at 1300 and at 1700 a steak and chicken dinner will be served.

WASHINGTON HAMFEST
Two-Day Program

by W7BUN

The Washington State Hamfest will be July 11 and 12 this year. This event will be sponsored by the Radio Club of Tacoma and will be held at the Sportsmen's Chateau, 164th and Canyon Road, south of Tacoma. Activities include CW awards program, QLF and QAS contests, mobile judging and mobile efficiency contests, technical meetings, technical displays, QCWA display, manufacturers' displays, 75 and 10 meter mobile hunts, swap shop, hole-in-one contest, women's and childrens' activities, after-dinner program, many fine prizes, etc. Camping space available on the grounds, $1.00 per night with free electrical hookup; 3970 kHz, 50.5 MHz, and 146.76 MHz FM will be monitored for arriving mobiles. The fee of $5 includes Saturday evening dinner and registration

ZL SSTV OK!

The Wireless Institute of Australia reports that slow scan or narrowband TV has been approved by the Postmaster General for use on all amateur bands as presently authorized in Australia.

Standards to be used are entirely at the discretion of the amateur, although bandwidth of emissions shall not exceed that of an A3 single sideband or double sideband signal.

Where A3 and A5 emissions are used simultaneously on the same carrier frequency, the total bandwidth is restricted to no more than that of an A3 double sideband emission.

Identification is required to be by call sign in visual form on televised picture and by telegraphy on telephony sound channel.

EBRC Spring Picnic

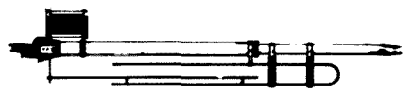
Saturday, May 2 at NAPA Valley Ranch Club, is the date and place for the spring picnic. The activities will include operating, archery, hiking, possibly swimming, ball games, etc., Guaranteed sunshine! There will be a nominal charge per person. Bring your own food.

ATLANTA HAMFEST

The Atlanta Radio Club will hold its 44th annual hamfest June 13th and 14th at the North DeKalb Shopping Center. The main prize is a Swan 500C transceiver with ac supply, along with many others. There will be many contests for the amateurs as well as games and other activities for the ladies. Further information may be obtained from John Fearon, 3384 Peachtree Rd., N.E., Suite 705, Atlanta, Ga., Tel. 261-4924.

News, Reviews, Announcements

Hawaii SCM to QSL for Kure
Notes 1969 Log Entries Not Valid



Lee R. Wical KH6BZF has announced that he is managing the QSL end of the DX business for KH6EDY, Kure Island, and that he holds that operating logs dating all the way back to January 1961.

In his report, Wical noted that some of the 1969 operations appeared to be invalid. The logs, he said were not, in all cases, properly signed in accordance with Section 97 of the FCC Rules and Regulations. He held hope for nonconfirmed contacts, however, by adding that QSLs for these occasions would be "handled on a case-by-case basis."

Wical listed the criteria to be met for stations expecting DX credit for Kure: U.S. amateurs must include SASEs; bureau cards will not be accepted. Do not send cards direct to Kure, as loss will be an inevitable result. DX stations must include SAE plus two IRCs for surface mail (or four IRCs for airmail).

Attachment Adds New Band to 4-Band Vertical

Mosley Electronics is marketing a conversion kit that includes a coil used to expand the Mosley 4-band vertical antenna to 5 bands. The added band,

will be publicized during the hamfest drawing, and in our Club's monthly newspaper "The Halo." Please contact Jack Hellwig K9ZWU, Prize Chairman, Six Meter Club of Chicago, Inc., 3420 S. 60th Court, Cicero IL 60650.

FERMANAGH FESTIVAL

Activates GB3

by Sean MacMahon G18AWF

For the second year running an amateur radio station will be established for the duration and in conjunction with the 1970 Fermanagh Festival.

The station, GB3FRE, will be in action at the Townhall Enniskillen, from Friday, June 19 to Sunday, June 28. At least two fully equipped operating positions will be set up. Operating time, which will be mainly in the evenings, will be spent most of the time on 160, 20, and 15 meters, sideband and CW.

The principal objects of GB3FRE, are:

(I) To enable hams throughout the world to have a contact with this rare county.
(II) To publicize Fermanagh.
(III) To interest members of the public in Fermanagh and elsewhere in amateur radio.

A special QSL card will be issued to all stations from whom a QSL is received.

Last year GB3FRE was in great demand and worked approximately 800 stations in all continents.

20 Meters

All stations having traffic for the L.A. area are invited to check into the Southern California Amateur Network, 14.325 MHz, 0500–0600 GMT, Monday thru Friday.

(Children under 12, $1.50 for dinner only). Logger's breakfast served by the club Sunday for only $1.25. Snack bar open both days. All dinner reservations must be made in advance. Contact John Austin K7CZF, 8478 Eastside Drive N.E., Tacoma, Washington 98422, for information, motel reservations, or hamfest tickets.

Champlain Valley Hamfest

The annual hamfest of the Champlain Valley Amateur Radio Club will be held July 19 starting at 10:30 a.m. at the club shack on Akey Road, Cadyville, N.Y. (7.2 miles west of Plattsburgh on Route 3.) Food and beverages available on the grounds, talk-in on 146.34-146.94 FM (W1KOO) and 3925 Kc. SSB. Send advance registrations ($1.50) to CVARC, Box 241, Cadyville, N.Y. 12918.

ERIE, PA. BANQUET

On Saturday, October 10, 1970, the Radio Association of Erie will be holding its annual dinner banquet. This is our 25th year of serving the ham and community, having been founded in 1945. A part of our program features the giving away of door prizes which are donated by local stores, as well as various gear from manufacturers and distributors. The Radio Association of Erie would be honored to have companies represented at our dinner and W3GV would be happy to distribute the literature and will provide advertisement in our monthly paper, the *QUA–RAE* in return for any donation. Please send any donated material to: The Radio Association of Erie, c/o John Gebler, PO 844, Erie PA 16512.

Charles Ercolino Named Telrex President

C. Charles Ercolino has been elected president of Telrex Communication Engineering Laboratories, Asbury Park, New Jersey, manufacturers of TV and communications antennas. He succeeds his father "Mike" Ercolino who will continue as chairman of the board and chief engineer.

Charles Ercolino is a graduate of Youngstown University with a BS in business management. He started with Telrex as a salesman traveling the country extensively.

In discussing this change in leadership, Mike Ercolino said, "The time has come for Telrex to expand both its TV antenna line and its communication antenna systems. To do this, we need the vitality and modern marketing methods which stem from younger people. I look forward to being able to devote my time to research and development as well as supervising the construction and installation of our 'Big Berthas' and other highly sophisticated arrays for which Telrex is noted. I have enjoyed every minute since we established Telrex nearly fifty years ago. Now it's Chuck's turn and I know he'll do a good job."

75/80 meters, is incorporated with a special coil rated at 2000 watts PEP that attaches to a condenser tube fitted over the vertical element of the original vertical (RV4C). Tuning is accomplished by sliding a U-shaped matching rod along the vertical element until the desired frequency is attained. According to Mosley spokesmen, the resultant vswr is 1.5:1 or better.

VHF'ers PICNIC

The Mt. Pleasant Amateur Radio Club cordially invites you to attend the southeastern Iowa VHF'ers picnic to be held at McMillen Park, Mt. Pleasant, Sunday, July 12, 1970 from 9 a.m. Pot Luck lunch, free coffee, trunk sales. All hams welcome, no charge. Rain or shine, shelter provided. Talk-in on 50.480 and 3.950 MHz.

Lancaster and Fairfield County Hamfest

The Lancaster and Fairfield County Amateur Radio Club is pleased to announce their annual hamfest to be held this year at the Lancaster Fair Grounds in Lancaster, Ohio, Sunday May 31, 1970. The club will be happy to accept any prize contributions, large or small, for use as door prizes. If further information is required, please write for reply to Howard Schaefer, President, The Lancaster and Fairfield County Amateur Radio Club, P.O. Box 3, Lancaster OH.

Massachusetts Amateur Radio Week

Worked all Massachusetts cities & towns

These two contests under the auspices of the Massachusetts Chapter of the National Awards Hunters Club will take place the week of June 14-20 from 0001 GMT June 14 to 2400 GMT June 20. These will run simultaneously during this week which has been proclaimed by the Governor as Massachusetts Amateur Radio Week.

Dayton Hamvention A Real Blockbuster

by K6MVH

The Dayton Hamvention was the biggest smash success of any ham convention I've ever seen. Records showed that more than 4000 hams passed through the halls at Hara arena in Dayton to see the wares being exhibited by the manufacturers. The flea market area, where hams from all over the country displayed their goods for sale and trade, covered a seemingly endless territory from the arena proper to a dirt area a jillion miles from the buildings. Money changed hands faster and more furiously than in a Las Vegas casino, and many hams bought and sold to such an extent that they were able to run up a modest purchase into an impressive shackful of equipment.

The convention area was several miles from the nearest hotel, which might have presented a problem for many out-of-staters who flew in for the occasion. Anticipating such logistical dilemmas, the Hamvention planners hired buses that ran regular schedules during the convention. The distributors themselves, however, with their heavy displays and other exhibit material, found themselves in a veritable "transportation bind."

The 73 booth was so active that all the magazines and books I had taken were gone the first night of the Hamvention. If I couldn't get more from Peterborough I would have been out of business. A quick long distance call got more books loaded onto an airplane, but there was still the problem of getting the merchandise from the Dayton airport to the arena.

Thanks to the traditional ham spirit, as exemplified by Steve Holden

FREE SPEECH for HAMS?

by K2AGZ

If you read the May issue of 73, and I hope you did. . .and if you happened to see the lead story in the recently inaugurated Radio News Page, and I would be disappointed if you hadn't. . .you are aware that we may witness, eventually, some sort of court test of FCC Rule 95.83(a) (3). This rule spells out prohibitions of ". . . obscene, indecent or profane language, words or meaning." Commissioner Nicholas Johnson, in a detailed statement, which the Commission published as an appendix to Docket 18804, expresses serious reservations as to the constitutionality of 95.83(a) (3), due to an apparent abridgment of the guarantee of free speech, as explicitly cited in the First Amendment, part of the Bill of Rights.

This matter is of particular significance to amateurs because of the dialog which followed a specific editorial in QST, in which it was stated by inference that the FCC did indeed have the right to suspend or revoke ham licenses on these specific grounds, and in which the editorial took the position that free speech, while it may be guaranteed in all other respects in our society, may be undesireable on the ham bands. 73 disagreed with QST's position, as expressed in Leaky Lines. And the correspondence which was subsequently published in QST showed that there was disagreement among rank and file ARRL members also. In its editorial, QST also sanctioned the activities of a group of self-appointed monitors and vigilantes, who constantly roam the bands, gratuitously offering opinions and advice in the form of unsolicited and unwelcome anonymous comment as to the appropriateness or acceptability of other people's conversation. They were sanctioned thus, entire text of Johnson's statement. We urge you to refer to page 2 of the May issue of 73, for the text. Although it is merely an opinion, it is certain that it reflects the views of a growing body of persons with profound misgivings with respect to an apparent drift of public confidence away from the Bill of Rights. A growth of willingness among the public to repeal such guarantees, all of which are fundamental to our system, makes it particularly important to focus attention upon the dangers of a too equanimous approach.

This is a deadly serious matter, and merits the undivided attention of every American who values our way of life, for if ever we allow these time-tested cornerstones of our Constitution to be eliminated, we would be opening the door to the most heinous form of totalitarian tyranny. . .that of mob rule!

At this juncture, I can almost fancy that I hear the voices of some of my best friends, even, saying that I'm going crazy, for how could anything so unimportant as this possibly result in any type of totalitarian takeover.

So that there may be no ambiguity about this point, let me enlarge upon it and examine it. The Bill of Rights, basic threads in the fabric of our democracy, came about as a result of the experiences of other nations where no guarantees existed. Indeed, they were unique because they had never been embodied in any *corpus juris* prior to their adoption here, in our Constitution. This was a new experiment; untried and unheard of. There was but one purpose in them; to guarantee the rights of all citizens who might hold minority views at variance with the views of the majority. If you study them, you will find this implicit proved ability to tolerate all sorts of differences of opinion. We do not require the sort of conformity which would guarantee our leaders a type of authority minus checks, balances, or criticism. Our country is the best on earth because of this apparent contradiction; not in spite of it! And when we forsake this fundamental principle, that is the day we will begin to deteriorate into something less than the best.

The drive toward conformity of ideas, ethics, morals, dress, manners, standards, and goals, is fraught with the most fearful consequences. The most alarming result of all this is the seeming docility with which many persons are accepting the idea. We are growing so used to having the government rule every facet of our lives these days, we are beginning to lose our ability to think like free men. If we do not put a stop to it, we may be getting close to the adoption of the "Big Brother" system. (*Ed. note: 1984 is less than 14 years away!*) That would be the end of our free society.

Commissioner Johnson recognizes this. When we go on the air and voice opinions, no matter how distasteful they may seem to some, we are guaranteed the right to express them, as spelled out in the Amendment. Until there is devised a meaningful set of standards which will clearly delineate the limits in unmistakable and unequivocal terms, then no one has the right to muzzle us. . .not the FCC, the Vice President, the attorney general, or even some self-righteous hams, who appoint themselves the sentinels of public morality.

The Constitution was never meant to provide anyone with a guarantee against somebody else's freedoms to

K8RZL, the problem wasn't one after all. Steve, the trustee of Toledo's FM repeater, not only made the trips to and from the Dayton airport, but he made his services available to 73 on a no-strings basis throughout the whole convention.

It is sometimes difficult to determine what makes one show such a phenomenal success and others no more than adequate. Looking back and analyzing the convention objectively, I can see several factors that might be key contributors to Dayton's popularity. Other convention planners take notice:

Plenty of active on-the-air exposure, with continuously manned talk-in frequencies.

Carefully planned and well executed advance advertising and coordination, including interesting publicity releases.

Saturated publicity around Dayton. Motels carried special "welcome" signs, a Foster & Kleiser billboard screamed out the Hamvention message, and special buses sported huge banners giving the essentials.

An atmosphere of friendliness pervaded the arena. This is extremely important, and was handled professionally and proficiently by the Dayton Hamvention people. In many conventions, you get the feeling everyone is after your money – but not at Dayton. The local amateurs, for example, set up a coffee and donut area the first night, right on the convention floor; a large sign told the world the goodies were free. And there was plenty of refreshments to go around.

Local amateurs participated in the convention, giving the impression that they really cared about how the attendees felt. K8RZL's support to 73 was but one example among many.

The ham booths were taken seriously, carefully prepared, continuously manned, and were not "junky" in appearance. The FM booth, in particular, was a winner. The clever local FM group which operates on the local repeater output frequency of "seven-six," managed to get some advertising gimmicks from Union Oil Co.'s "76" gasoline promotion campaign. They were able to display a huge orange ball with a boldly imprinted "76" in the booth, and distributed smaller versions of the balls to local FM'ers, who fixed them to the tops of their handie-talkie antennas.

The safest way to assure a successful ham convention, it would seem, is to plan all activities, promotions, meetings, and logistics well in advance, and to treat all attendees with as much respect as you'd show your own relatives. And after all, aren't we all related anyway?

despite the fact that they, the vigilantes, are in clear violation of a totally unambiguous rule pertaining to station identification.

It now appears that there are serious doubts, not only with respect to the previously condemned use of prohibited styles of language, but also concerning the very rule which spells out such prohibition. We have always contended that since there are no precise standards for permissible speech over the air, and that those standards which do exist merely reflect an arbitrary individual point of view, depending upon the criteria of the party in judgment, then it is clearly an abridgment of individual liberty when speech is limited, so long as such limits are not in conflict with what is clearly against the Constitution, as in cases of sedition or treason, as spelled out in the Smith Act, for example.

We cannot, of course, reprint the

in each and every one of the Amendments of the Bill of Rights. The First assures freedom of speech, press, and the right to petition for redress of grievances. It also guarantees against laws respecting an establishment of religion, or prohibiting the free exercise thereof. This is clearly designed to protect the rights of minority opinion. And the others are similarly designed, whether the Fifth, which protects against self-incrimination; the Seventh, which guarantees trial by jury; the Fourth, which prevents unreasonable search and seizure, or any of the others. They were created explicitly to protect those who might hold minority views, and to protect their right *to express* those views.

There happens to be, however, a very strong current running just now, encouraged by powerful persons, including the Vice President, which opposes the spirit of these Amendments. Mr. Agnew keeps talking about the will of the "silent majority," and about the "liberal press which thwarts that will," and about "intellectual punks." He has been extremely vocal in his attempt to stir up public outrage against those persons and groups representing views which differ from the norm. A recent poll by CBS-TV disclosed that many people are now expressing willingness to repeal all or part of the Bill of Rights, and one cannot separate this growing willingness from the context of the Agnew statements and others. Consequently, the end result would be a stifling of all but majority opinion and majority will. . .clearly an example of the precise condition which the Bill of Rights was designed to avoid.

It must be stated here that I do not presume to tell the Vice President of the United States that he is wrong and I am right. I do not disrespect Mr. Agnew; I regard him as an articulate, capable spokesman for a point of view with which I happen to disagree, that is all. One thing I know. . .the strength of this nation is based largely upon our speak or think. Your freedom depends upon mine. And when I lose my freedom of speech, you begin to lose yours.

So where does all this leave us? It simply means that we come down to the same old standards we've always observed; common sense, good taste and tact. Speech cannot be legislated. Neither can feelings, instincts, ideas, thoughts, or tastes. Just as you cannot regulate prejudice by statute, you cannot impose a state of verbal unanimity. Goodwill can be found not in a law book, but in the human heart.

The point is, though, that when someone doesn't quite measure up to your idea and mine of what constitutes proper behavior, it may not be within the Constitutional rights of the FCC to deprive him of his license. This is the tenor of Commissioner Johnson's statement. If this view should be upheld in a court of law, it is likely to cause a great deal of change in ham radio.

But once again, we can recognize the deep need for a rewriting of the FCC regulations. This one ambiguity, resulting from the confusing language of the regulations, is like the proverbial one-eighth of the iceberg which is visible.

INDIANA HAMFEST

The Madison County (Indiana) Amateur Radio Club will hold its annual "Hamboree" on Sunday, July 12, 1970. Doors will open at 11 a.m. at the county Civil Defense Control Center located 4 miles north of Anderson at Linwood. Activities include a general get-together and flea market. Door prizes will be awarded thru the afternoon, and refreshments will be available. Talk-in freqs. 50.4, 145.35, 146.940.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

A Visit to Jordan

With nothing more to go on than a note in Gus' DX bulletin to the effect that King Hussein of Jordan had been heard on the bands fighting off tremendous piles of QRM, I sent a cable to him asking if he could use some help for a few days to beat down the multitudes. With Radio Today just being started and the tight U.S. economy making its pinch felt all too clearly on 73, I wasn't really too enthusiastic about my proposal.

On the other hand, the insurmountable problems at 73 have continued without any real letup for a long time, with me there or away, so perhaps a few days off wouldn't be too serious. And uppermost in my mind was the opportunity to possibly make a good friend for amateur radio, one who could have a strong long-range impact on the hobby. If amateur radio could be developed in the Arab countries this would not only benefit them tremendously by encouraging the growth of engineers and technicians, but would help amateur radio by giving it a few more votes at the ITU conferences in the future.

Much to my surprise an answering cable arrived from His Majesty asking me to come. Within a few days I was off to Jordan and whatever lay ahead. Where would the station be? At an army base? Perhaps in the palace? Would I be able to operate much? Would I get to do more than just meet His Majesty? Those of you who have been reading my editorials know that all sorts of ingenious plans for solving the mid-East crisis started coming to my mind.

When I checked in at the airport in Boston they suggested that I hand carry all films with me since all checked baggage is xrayed at London before going on to the mid-East. This called for a complete repacking of my bags in the black of the parking lot, and I ended up by carrying on two bulky bags full of cameras and film.

Lin didn't think I should go in my dungarees, so I hope the IRS will agree that the business suit I bought for the trip was a necessary business expense. You don't need business suits very much in New Hampshire.

The plane left Boston in the evening and arrived in London the next morning. As usual on these trips I managed zero sleep. They had some fool movie that I had seen so I saved the $3 for the earphones, but still couldn't keep my eyes off it.

After a couple of hours wait at London in the passenger lounge I was off again to Beirut. I'd written Bob OD5BZ there, hoping he would have time for dinner between my planes. Late that afternoon I arrived at Beirut, but no Bob. I found out later that he was out of the country on business. I put away a great Arabian meal at the airport restaurant and continued on to Amman on a Royal Jordanian Airline plane, landing there about 9:30, wide awake on my second wind, beyond being tired.

There was a big commotion outside of the plane, with newsreel photographers and all ... the man beside me said, "Look out there and see our King." Sure enough! I could end that there, leaving you with the notion that he had come to see me, but actually he was greeting his sister. I was met by a man from the palace who expedited my passport and bags through, told the King that I had arrived, and drove me in a beautiful Mercedes to the Jordan Intercontinental Hotel where I was to be the guest of His Majesty!

I slept.

The Hotel Jordan, as it is called, is an American style hotel ... showers, wall-to-wall carpeting, the whole bit. It has a serviceable coffee shop and a first rate restaurant on the roof. The "maids" are men, but they know all the ropes such as opening your door at 6 a.m. to see if the room is occupied. Just like America. They try the door again at 7 to make sure they were right at 6.

The next morning a phone call explained that a Mrs. Salti would be picking me up shortly. Mrs. Salti turned out to be the private secretary to His Majesty and a very nice looking English girl. She explained that there was some sort of big do on shortly if I would like to come ... I grabbed my camera case and we were Mercedes'd to the gigantic sports arena ... jammed with people. We sat up in the grandstand, not far from the King's box and awaited developments.

The "do" consisted of a couple hours of speeches, His Majesty presenting flags to a number of artillery groups, inspection, parades, and some really beautiful precision marching by both military and bagpipe bands. There were some-

what over 15,000 people in the stands for the big show.

Mrs. Salti delivered me back to the hotel and promised to pick me up later to meet His Majesty. She surprised me by arriving in her little Renault instead of a Mercedes and we were off to see the King.

We drove for some ten miles or more out of town, stopping at several checkpoints and gates along the way, ending at a beautiful two-story modern home atop a hill with a little vertical antenna on top. We were met at the door by His Majesty and shown into the study where he has his ham station. He has a Drake R4B, T4XB, L4, and MN2000 tuner. A nice setup.

During the next two weeks I operated the station using the call JY1 on a daily basis, usually operating from about 3 p.m. until 8 or 9 p.m. Since the station was installed in the King's home (palace) I appreciated that he and his family were not too anxious to have me sitting there around the clock. We did arrange for one all-night session in order to make JY1 available to the eastern U.S. stations who missed the 1300 GMT openings.

I had the opportunity to talk with His Majesty on many occasions, sometimes for an hour or so. I found him to be interesting, well informed, warm, friendly, and reasonable in every way. I in no way found an emotional and intransigent Arab leader. He is modest, rather shy, and gracious almost to a fault. The list of problems he has to face would fill a book . . . a lack of resources . . . shortage of water . . . lack of power facilities . . . extremist groups galore . . . little industrial capacity . . . undeveloped agriculture . . . recent loss of a large part of his people and the most productive and advanced territory (Palestine) . . . a loss of brainpower to more developed countries . . . a loss of money from the wealthy to safer banks in Switzerland. . .

Bleak as the picture might seem to be – and I should hasten to say that His Majesty offered no complaint, only optimism – the list above is one I gleaned from talking with others. He has accomplished miracles already, considering what he has to work with. The State Department paper on Jordan is most enthusiastic about the rapid strides that Jordan has made in the last few years since King Hussein came to power at 17 years of age in 1953.

One evening I was invited to dinner by His Majesty. Along about 10 I joined the family in the living room watching television. The children were off to bed much earlier (twin girls, two years old, and two boys about five and six). With His Majesty was his English wife and her parents, his sister and her husband, etc. Dinner was served and we went to the dining room. There was an oval glass-topped table about 12 ft long, just loaded with dishes of food in the center. We sat down and helped ourselves family-style to roast lamb, hamburger patties on rice, salad, cheese omelette, ad infinitum. For dessert, sweet fresh strawberries and whipped cream.

After dinner we all got in the cars and were off to the downtown palace for a movie in the King's private movie theater. The feature this night was billed as a comedy, but it was "If," and the imagination has to be stretched a lot to call that grim exercise a comedy. Mrs. Salti dropped me at the hotel at 2 a.m.

Well, so much for the royal life . . . now, what about the ham radio end of things? I did manage to get quite a few stations contacted, even with the time restrictions. I doubt if there are any stations in Europe with any serious interest in DX that have not contacted JY1. For that matter, there really should not be many stations around the world that missed working JY1, if they set their minds to it.

For the most part I found everyone most cooperative and helpful on the air. There were exceptions, of course, but they were exceptions. One of the biggest problems in this area is the wonderful propagation just about around the clock into Italy . . . or should I say from Italy into Jordan? Couple this with the absolute fact that somewhat over 90% of the Italian operators do not understand one single word of English and have no intention whatever of not making a contact exactly when they want to, no matter who else is involved or what they want. I am afraid that I am guilty of taking advantage of this once or twice, being quite insulting because I knew darned well that the offending station would not understand. For instance, only once during the entire two weeks at JY1 was I able to get through to my home station and actually hear them. All through this contact I1VEL continued to call almost continuously, ignoring the most pitiful pleas to wait. You might think that the best answer to this is to just sigh and go ahead and let him make his contact. This is probably so, but it is discouraging to know absolutely certainly that this chap is going to have a very long name which he will spell phonetically twice for you, followed by an even longer city name which he will also spell twice phonetically. Then he will demand to know my name and where to send the QSL card and will not be placated in any way until he gets this information spelled out phonetically twice. Since I had to go through this routine well over a hundred times I am absolutely certain that one of the worst enemies of our hobby yet to turn up has been licensing Italians and giving them a card with their contacts all spelled out for them. All they have to do is read from the card to make contacts and there is no need whatever to understand any English.

There are other devils to slay. While I found most of the USSR amateurs quite polite and cooperative, I must say that the bulk of the really rotten signals also came from their direction. They have a virtual monopoly on bad signals.

Most of the time I was quite successful in using the transceive system of operating. About

(continued on page 140)

I've been dying to talk about New England, and now that the boss is gone, there's no one to stop me. Wayne got an invitation to spend a few days with Jordan's King Hussein, and like a lightning flash he was gone. Now if I can get this editorial into print before he gets back, I'm home free.

The reason I wanted to talk about New England is because I am an impressed Californian. I was born in California and I lived there all my life. Like most other out-of-staters, I had heard a lot about New England, but nothing that would warrant making me want to go there for any length of time. But now I'm here and I'm hooked on the place. (Imagine – four different seasons every year!)

Now, I'm a ham and this is a ham magazine, so I don't suppose I'll be readily forgiven if I deviate from the track for any elaborate travelogs. But I feel like Wayne must have when he got his International Crystal Co. microwave oven – it's so great I *have* to talk about it. There's a whole new realness to American history when you live in New England. It's so easy to get all the behind-the-scenes facts.

Take Paul Revere, for instance. Now, it could be that California schools are a trifle uninformed when it comes to historical events that took place before the state was even a territory. And I might be basing my judgment on Longfellow's misleading "Midnight Ride" epic. But since I came to New England I have learned that old Paul was only one of several who spread the word about those consarned Redcoats. And he failed his main objective – to get word to the citizens of Concord that the King's "Regulars" were high-tailing it from Boston to confiscate or destroy supplies that the Provincials had stored in and around Concord.

Paul took off from Boston all right. He split as soon as he and his companion learned how the Regulars would be traveling. Just a jump and a half ahead of General Gage's troups, Revere and his companion, Dawes, went riding toward Concord. They stopped in Lexington with a message for upstarts Hancock and Adams (the Hoffmans and Seales of the day). Part of the British troops' assignment, they said, was to arrest these rebel leaders. So when John Hancock and Adams were safely salted away, a Dr. Sam Prescott suggested they head on up to Concord to warn the unsuspecting colonists who were storing arms.

Concord wasn't too far away, so the three of them – Dawes, Revere, and Prescott – set out. At about the halfway point, they were met by a British patrol. Dawes fled back toward Lexington. Revere was captured. But the real hero, Dr. Prescott, was the only one of the three who made it to Concord, and he passed the word.

A few hours later, when the troops did march into Concord, they met the first resistance of the war. And at the outskirts of Concord that same day, the famous shot, described by Emerson as being "heard round the world" rang out, and several soldiers – on both sides – fell dead at the old north bridge. Not 200 yards away, from his bedroom, William Emerson, the father of Ralph Waldo, watched the entire incident, a fact which doubtless helped to inspire the younger Emerson when he phrased those immortal words about this initial action.

Is that the way you learned it in school? Well, it wasn't the way I learned it either, but that's the way it really happened.

Someday, when I really feel brave, I'd like to tell you about my experiences in homebrewing maple syrup: what happens when you confuse the sap from a diseased elm with the good stuff from a sugar maple, and the curious effects on wallpaper when the kitchen stove is used for the boildown process. Later, though – I've taken enough chances for one issue.

A Word to Authors

A very large percentage of you readers are part-time authors. Sometimes you write articles for 73; sometimes for Ham Radio; and sometimes for CQ. Rumblings have been finding their way recently from more and more of you fellows that payment for your services is not always easy to come by. One of our top authors even offered to write an exposé for us on the pay-avoidance policies of one of the other ham journals.

Specifically, the complaint seems to be that when an author submits a manuscript to one of the journals, an acceptance or rejection is received within a reasonable period – several weeks to two months. But when the article is accepted, the authors tell us, there is an inordinately long period of waiting before the publisher makes out a check.

As a parenthetical "aside," it is perhaps time for me to interject a word or two about 73's policy with respect to manuscripts: When articles come into my office, I evaluate them as fast as I can, usually within a few days. I place the rejects in a special basket for return to the authors. The accepted articles are graded for amount of editing required, interest value of material, eye appeal of photos, etc., and a dollar value is assigned. The article is placed in a folder and given to the bookkeeper for payment. Nobody in the production department can touch that article until it has been paid for and returned to me, the editor. There is practically no way for an article to sneak into print without being paid for first. That's our system and it was established by Wayne because

of some bad experiences he had with a former employer who let a number of authors down. Wayne has religiously upheld his emphatic resolution that it won't happen at 73.

All this notwithstanding, there are increasing numbers of reports that authors are being shortchanged by some of the publications within the amateur fraternity. Perhaps some of the authors are afraid to say anything for fear of being blackballed. But it is the journals who should do the fearing – suppose all top authors blackballed one ham publication; who then would bother to read that journal?

Maybe 73 can help. You readers who are part-time authors let me know the problems you've had trying to collect money for your material after it has been published. I will compile a record of your experiences for publication in 73. If you'd rather your name not be mentioned, you can just tell us the essentials along with a request for anonymity, and we'll have the facts that, once published, will help future authors.

To be quite frank, I am not totally naive in this issue. Before I came to 73 I submitted articles to other publications from time to time. In one instance I had to wait for five months after an article was in print before I got paid for it, and even then I was only paid after writing several unfriendly letters to the publisher. I suspect that prospective authors will begin to get better treatment if the guilty publisher reads this editorial and realizes that he'll be getting some undesirable publicity.

Be fair when you write and tell us your experiences. If you've contributed articles to the other journals and have received immediate payment, we'd like to know about that, too. There's no point in printing only the bad if there's even a grain of good in there somewhere.

Magic Ears

People sometimes get curious expressions when I refer to Wayne Green as "Magic Ears." But I have good reason; old Magic Ears hears everything. His office is on the third floor, in what we laughingly (and realistically) refer to as The Garret. Now, The Garret is a long way from just about everywhere; even those CB walkie-talkies barely hack it from Wayne's office to mine. Boistrous activity can be in full blossom in The Garret while the rest of the place is as placid as a churchyard at dawn. All kinds of things happen up there; radios go in and radios come out – desks are moved hither and thither – test equipment gets stacked up one day and vanishes the next – bookshelves come and go. But there's never so much as a stir as far as the rest of the inhabitants of 73 can hear.

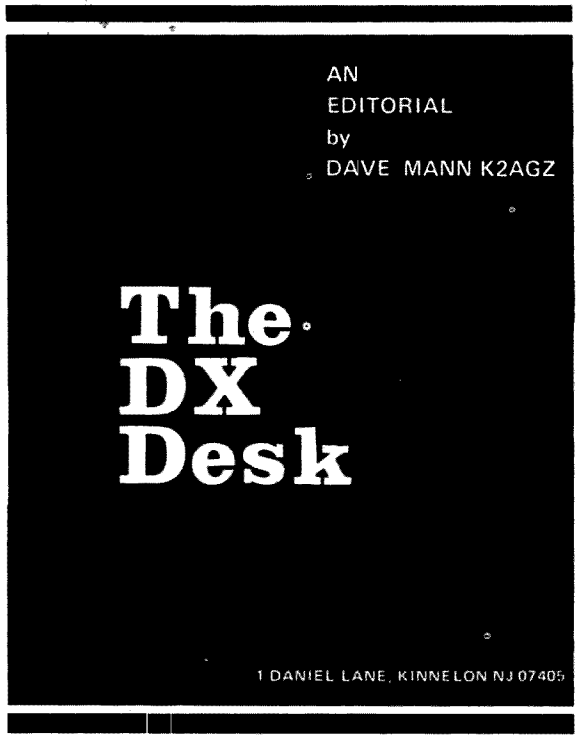
It seems only logical that if what happens in The Garret can't be heard downstairs, the converse must also be true. And maybe it would be true except for that special ability of old Magic Ears. Three floors down and a hundred yards away a printing press will stop running. Seconds later, there's Magic Ears, wondering what the holdup is.

Two flights down and on the other side of the mansion from The Garret, an interesting but quiet discussion will develop. At about the high point, in will walk Magic Ears, completely prepped on all facets of the discussion that have taken place before his entry.

But the most fascinating aspect of Wayne's phenomenal ability is when he's operating the station. He hears calls, locations, facts and figures, names, and other vital statistics when I would swear there's nothing but noise coming from the speaker. The last time it happened, I sat down beside him at the operating table with my ear glued to the speaker; I was convinced he was putting me on.

Right after he put out a short CQ he pressed the transmit switch and called UV3FD in Moscow, seemingly returning a call. There were several short exchanges, and each time I strained my ear at the receiver trying to hear the drummer Magic Ears was marching to. I watched him fill in his log: 0420Z, UV3FD, Al, Moscow. If I were to tell you that I was skeptical I would be grossly understating the facts.

But believe this or not – and I can still hardly believe it myself – some semblance of a signal began to work its way up through the mire there on 14.205. And suddenly, amid the din and garbage that characterizes 20 meters, there was Al. He had been asked about his occupation and was making his retreat after "an enjoyable discussion." Calling Wayne by name, he then signed off, giving both his call letters and Wayne's.



I don't know how he does it. But don't feel bad if you enter a contest and get beat out by Magic Ears. That's the breaks – some of us have it, some don't. ... K6MVH ■

"Not Yiddish, you lid! British!! Bravo, Romeo, India..."

If the attitude of some amateurs is to be credited with any validity, there would seem to be a grossly misunderstood provision of the regulations, or at least of the FCC interpretations and administration of those regulations. I refer to the rules governing third party traffic.

There are cases in which it would be normally assumed that violation notices would inevitably ensue. But there are other instances which pose some doubt. There is an area of ambiguity in the minds of many, although the rules are spelled out with clarity. I find the following passage in the ARRL License Manual, page 65 in my issue: "Amateurs may handle, in emergencies, traffic relating directly to safety of life or property."

In a recent instance during the passage of priority emergency medical traffic, some overzealous, self-appointed vigilantes were heard to make snide comments, causing unwarranted interference, and making pests of themselves. A physician-ham, WA2RAU, was attempting with difficulty to ascertain the exact particulars of a life and death case in an African locality, in order to determine the proper drug shipment to the patient's doctor. The traffic was finally passed, but it took four times as long as it would have taken if it had not been for the interference from persons who took it upon themselves to intrude. It could be that in their determination to horn in, they themselves might run afoul of a few regulations and run the risk of violation notices. And in this particular instance this would have been poetic justice, in my view.

In order to clarify this situation concerning the rules for third party emergency traffic, the FCC District of Columbia Bureau was called. A man named Mr. Sam Ferraro gave the caller permission to quote him directly. This is what Mr. Ferraro said:

> "Under any circumstances, emergency, that is, life and death traffic, is permissible by the FCC with *any country*."

He stated further that the Commission will not prosecute any ham for handling any emergency traffic with any country. In other words, not only is such traffic permissible, but the FCC policy is that it does not wish to discourage it by implying any threat of prosecution or other punishment.

Unfortunately, there are some who insist upon complicating the simplest matters. Certain net control stations, in spite of Mr. Ferraro's assurance, have stated that they would still insist upon *written permission for each such emergency*. This rigid approach, sadly, does not fit in with the nature of emergencies! While an operator is chasing around in order to satisfy these requirements, cutting all the red tape strung by these petty, picayune martinets with their own homebrew regulations, a seriously ill human being, waiting for a life-saving drug, might be expiring in his final agony!

Let's get it straight, once and for all. If there is a medical emergency, and if an amateur decides on the basis of the information that it is indeed a matter of life and death, therefore serious enough to fall within the limits of the regulations, don't let's all jump in to advise him of the third

party rules. . .he knows them as well as we do. And he is mature enough to determine for himself the consequences of his own actions, without reminders from the rest of us. All we succeed in accomplishing with our unsolicited advice is to cause confusion and interference.

If the stations require relaying, translation, or other assistance, they will request it. But there is nothing worse than the bedlam caused by a mob, all talking at once, making nuisances of themselves, when a life may be hanging in the balance.

And while on this subject, I would like to toss a few orchids to those intrepid doctors among us, who have been doing this mercy work, to the everlasting credit of ham radio. The aforementioned WA2RAU, Sam Rosen, has been involved in so many such jobs that it would be impossible to calculate the numbers of lives which have been affected. Of my own knowledge I can recall a few of these. Doc sent over $300,000 worth of drugs to a certain country. The certificate which was issued to him by this grateful nation states that the drugs were responsible for the saving of 38,000 lives. He spent 72 hours running continuously, working patches during the Alaskan earthquake a few years ago. He has pestered the large pharmaceutical houses, promoting these shipments of drugs, and arranging for the airlifts by which to transport them. The drug companies may regard him as a pest, but he always succeeds in getting them to send the drugs. And for that, he's more than willing to be called any name they can think of.

I've selected Sam at random. I can assure you that there are dozens of these dedicated men, fulfilling one of the finest functions a ham can possibly find. In my opinion, for what it's worth, I regard such drug shipments to be at least as valuable as the Peace Corps, in terms of enhancing the image of the United States of America.

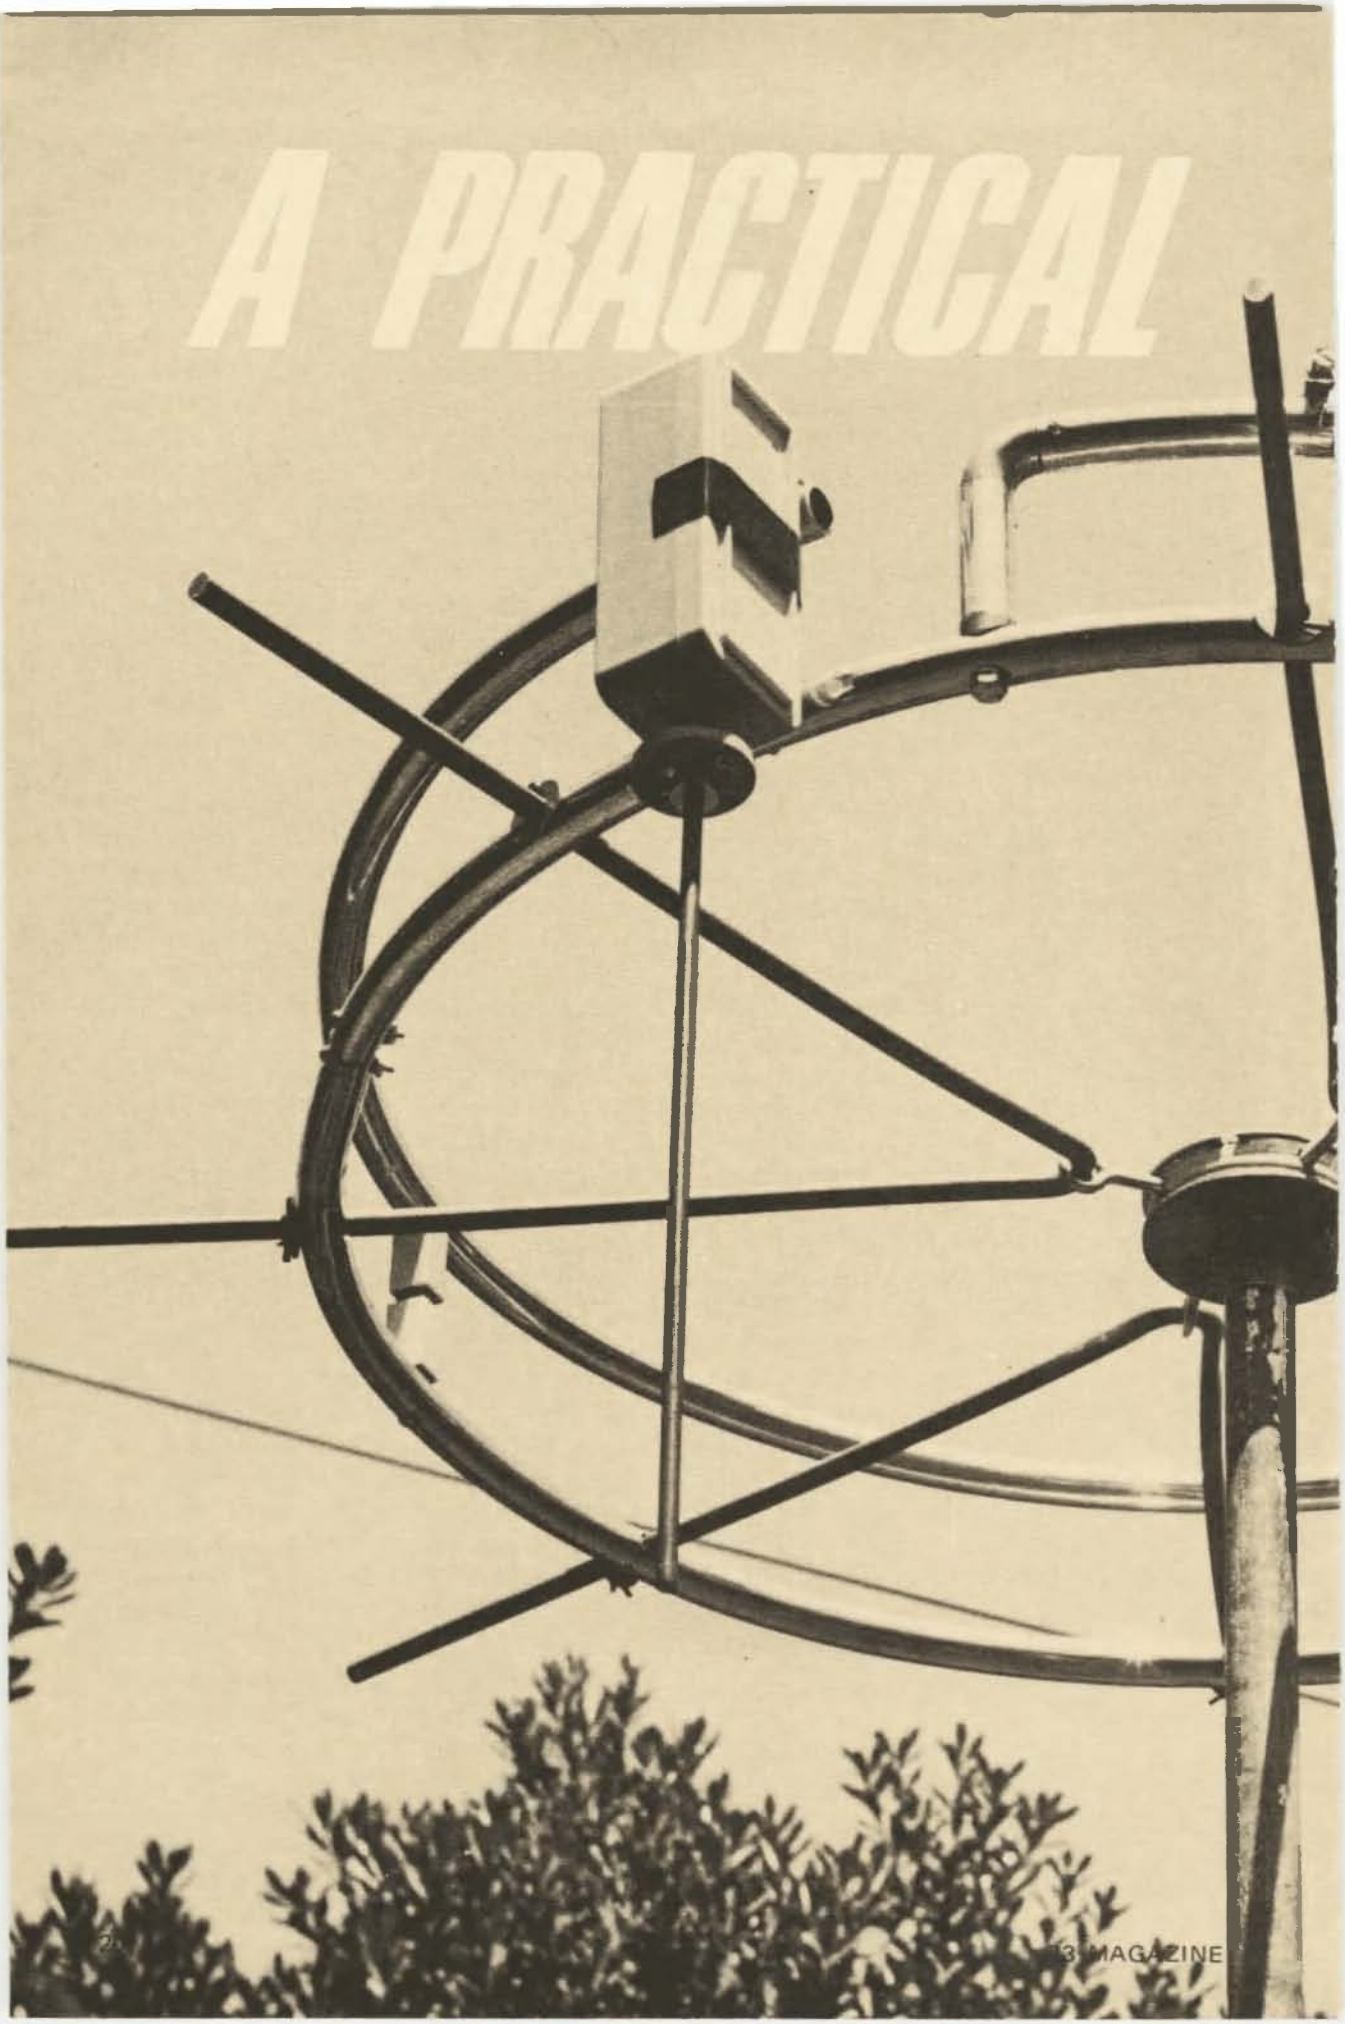
* * *

DX has not provided us with too many exciting events in recent months. True, we have had a new country, Market Reef, OJØMR, a rather surprising one which came out of the blue. AC3PT was activated for a short while by Dr. Fred Lieberman, a music professor from Brown University, who was in Sikkim to tape the songs of the hill people. That station is owned and operated by the Maharaja, P.T. Namgyal. He does not get on the air very frequently, and when he does, he becomes confused by pileups, and leaves as soon as the confusion begins.

There is current activity at Qatar, with a fine operation, MP4QBK, on both phone and CW on 15 and 20, with special permission from the Sultan. ZS2MI, Marion Island, has been coming through with booming signals. And W9FIU/KS4 has been 5/9 from Serrana Bank.

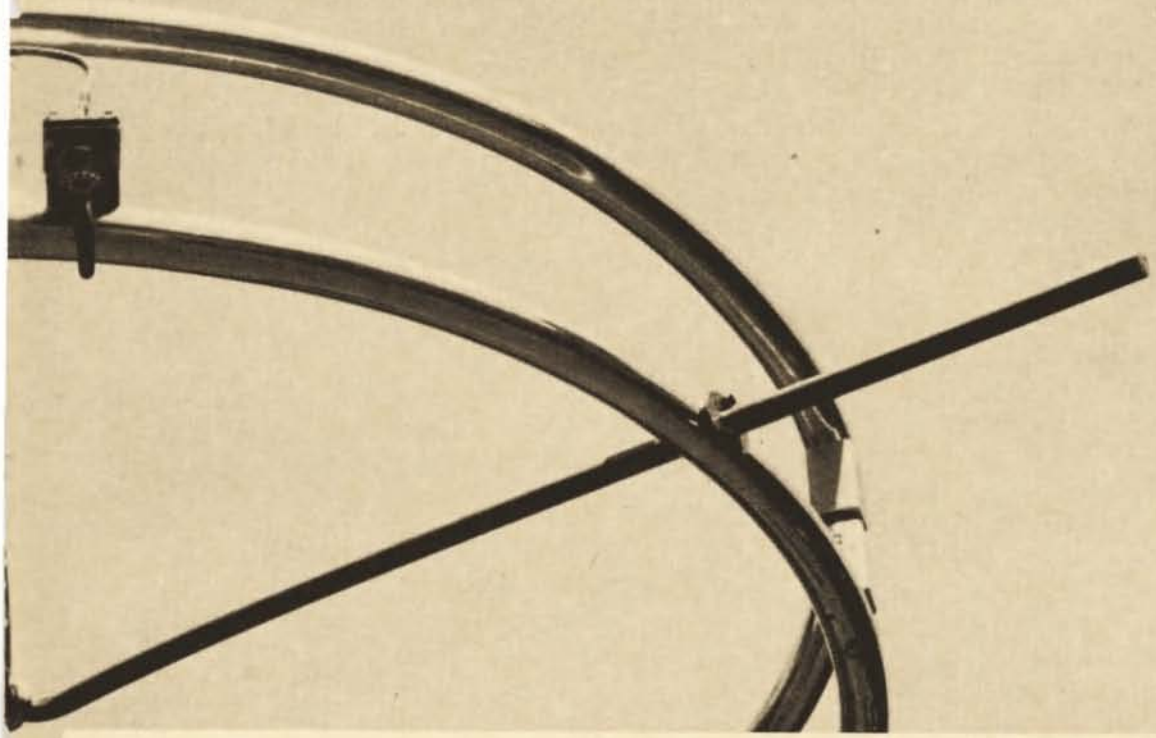
There are a few items due to come up this year which will make it a memorable one for the DX fancy.

One of the most exciting was Wayne Green's operation from JY1. This was one of the most intriguing prospects in a good long time, since JY is one of the most wanted prefixes on everybody's list. The JY episode, however, is Wayne's own story, and he's included it this month under "Never Say Die."



We hear all sorts of rumors concerning a French operator, testing on FO8, Clipperton Island. It is said that the chap is there on some sort of installation in connection with a satellite tracking station. It is further rumored that a regular amateur operation will be activated. This is another of the most wanted ones.

The projected Spratley expedition, which was due to begin shortly, has had to be tabled, due to a leaky schooner hull. Jens has slowly been making his way toward Hong Kong for the repairs, and then he is supposed to resume the trip. This one will take about two years, according to the best information, and should afford us a number of interesting possibilities.



Our old pal Gus is planning another DXpedition for the Spring, also. Let's hope that all the details are ironed out on this, and that Gus will be successful with all the preparations. It's just what is needed to give DX a shot of adrenalin and put some life back into the game. We've had some

(continued on page 143)

A PRACTICAL

DDRR ANTENNA

Since the DDRR (Directional Discontinuity Ring Radiator) was first announced by its inventor, J. M. Boyer; and the article by Clifford E. Hicks appeared introducing this new antenna to the ham fraternity, very little serious work has been done in this area. Yet this lightweight, compact antenna has many features which recommend it for use by hams. I, for one, have found it a most interesting antenna to work with. In spite of its many advantages the DDRR has some drawbacks which might discourage the otherwise interested amateur.

The two major problems are: construction difficulties which stem from the unorthodox (to the average antenna builder) fabrication of the DDRR, and the extremely high voltage which develops at the termination of the fed ring. The former tends to discourage experimentation because of the difficulty of bending tubing with reasonable accuracy and in arriving at a configuration with the mechanical stability that the sensitive nature of this antenna demands. The latter challenges the average junkbox to produce a tuning capacitor which will withstand the voltage and not

W. E. English W6WYQ
1841 Pinecove Drive
San Luis Obispo CA 93401

exceed the dimensions of the antenna itself. Indeed, it is difficult to locate a suitable capacitor for this service among the standard units available from the manufacturers. Another discouraging factor is the fairly large ground plane employed, which makes the antenna difficult to mount and gives it the appearance of a hovering flying saucer.

After working with antennas of this nature since 1965, I have evolved a design which overcomes, or at least minimizes, these problems. This design is such that any amateur, reasonably proficient with common hand tools, should be able to construct a DDRR antenna which will not only work well, but which is also easy to mount and easily equivalent to a quarter-wave vertical in performance.

For those who may not be familiar with this extremely interesting radiator, a brief description is in order. Essentially the DDRR consists of a quarter-wavelength element bent to form a ring, open for a small percentage of its circumference, mounted, horizontally, a few inches above a ground plane surface. The feedline is connected between one end of the circular element and the ground plane. It is usually tuned at the end farthest from the feedpoint by means of a low-capacitance variable condenser between the ring and the ground plane. (See Fig. 1.)

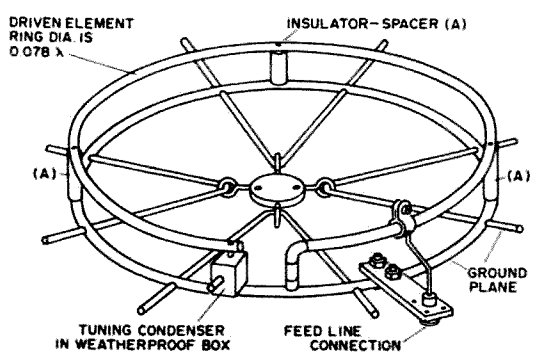


Fig. 1. Basic DDRR.

In contrast to its appearance, this antenna, like a ¼-wavelength vertical, develops a vertically polarized radiation signal. It is also interesting to note that this antenna displays exceptionally high Q and is sharp enough in tuning to be considered an additional tuned circuit in the communications loop. If the fed end of the discontinuous loop is grounded to the ground plane surface, the antenna can be shunt fed with coaxial cable (I used 50Ω RG-8/U and easily achieved an swr of 1.1:1). The physical size of the antenna is one of its most significant advantages. Since the ring is only .078 wavelength in diameter and the ground plane but 25% greater than that, with overall height for any frequency a matter of inches, it is easy to see that the DDRR is an amazingly compact antenna. The 10 meter antenna has a maximum diameter of 36 in. and an overall height of 4 in. The 2 meter version is almost pocket-size, 8 to 10 in. in diameter and 2 in. high.

The following construction details pertain to the 10 meter version of the DDRR. Tabular data in Table 1 provide dimensions

Table 1. Dimensions for antennas for other bands.

		10	15	20	40
Ground Plane Diameter	GPD	36"	50"	78"	135"
Feed Point	FP	1"	1.5"	2"	3"
Gap	G	2"	2.5"	3"	5"
Capacitor	C	15 pf	15 pf	35 pf	70 pf
Spacing	S	3"	4-3/4"	6"	12"
Tubing Diameter	TD	3/4"	3/4"	1"	1-1/4"
Radial Diameter	RD	3/8"	3/8"	3/4"	1-1/4"
Ring Radius	RR	28"	40"	54"	108"
	NR	8"	8"	12-16	12-16

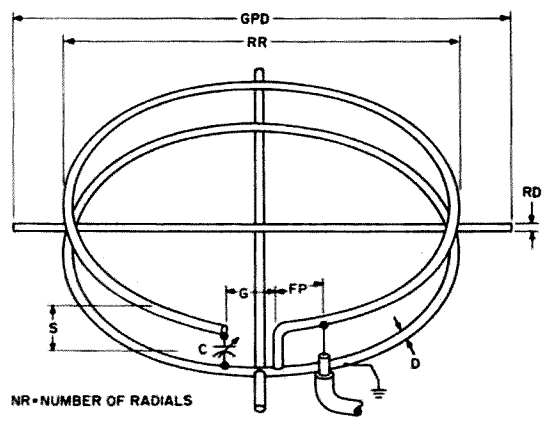

Fig. 2. Dimension key for DDRR.

for antennas for other bands. General construction details are suitable for all frequencies with sizes of assembly hardware being modified accordingly. Signifi-

cant variations, when they occur, such as with radials for low frequency units, will be described in detail.

Constructing the 10m DDRR

The solution to the construction difficulties mentioned earlier stems from use of standard hardware items commonly available in hardware stores throughout the country. If all of the recommended materials are procured before construction begins, assembling the DDRR should be little more difficult than assembling a kit antenna from the commercial supplier. (See Parts List, Table 2.)

Misc. Hardware – Lockwashers, washers, cotter pins, pipe clamps, etc. (See Text)						

[1] This is an electrical light fixture box known in the trade as a "Pancake Box"—other numbers are Bowers 410, Appleton 4-CL, Raco 293.

[2] This is a Butter Dish, the Loma Classic Flair, manufactured by Loma Products, Fort Worth, Texas, available in department stores, hardware stores, etc.

[3] The larger DDRR antennas require greater spacing between elements. We found it best to make insulators for the larger units from plastic stock. The selection of these items is left to the ingenuity of the builder.

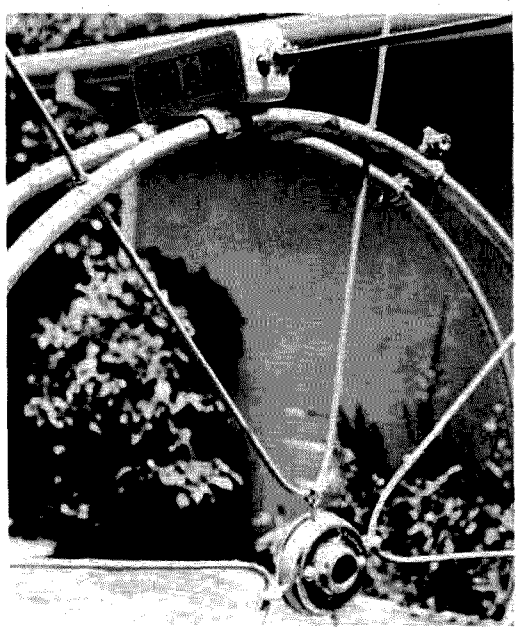
[4] Standard 1/2 inch EMT (Thin wall Conduit) can ba substituted wherever Reynolds 4222 is specified. The Reynolds fittings can be filed to adapt them to the slightly smaller inside diameter. The prototype antenna seen in many of the photographs was made with EMT. If you wish to make this substitution, you can save money, but there will be about a 30% increase in weight.

Forming the Rings

In my experience, the most difficult operation is bending the tubing to form a 28 in. diameter circle. In the pilot model the tubing was bent by hand (with a little assistance from the foot) and satisfactory results were achieved; however, a more esthetic appearance will result if a jig is used. A 26 or 27 in. bicycle wheel with the tire removed is satisfactory for this purpose. There is sufficient spring-back in the tubing to allow for the slight difference in diameter. With the wheel locked so that it will not rotate, position one end of the tubing in the groove of the rim and secure it. This can be done with a C-clamp, a vice, or simply by wrapping a few turns of wire around the rim and tubing. The free end of the tubing may be pulled around with even pressure until the complete circle is formed. If you do not achieve a perfect circle, no serious electrical problems will result; moreover, minor deviations can be corrected by tightening the radials later. The principal objective is to make two rings as close to circular and as similar as possible, with a center-to-center diameter of 28 in. When this task is completed, your DDRR is practically finished because the remaining construction is very simple.

Assembling the Ground Plane

Join the ends of one of the rings using the coupler (Reynolds 7840). Be sure to allow for "makeup" for inserting this part. To do this, the total circumference of the ring should be cut ¼ in. shorter than required.



Measuring around the outermost perimeter of the assembled ring, divide the entire ring into 8 equal parts. This spacing, measured around the perimeter, is approximately 11¼ in. Mark each division on the centerline of the tubing with a center punch. Drill completely through the tubing from the center punch mark toward the center of the ring with a 7/16 in. drill. These drilled holes are for the radials.

Cut the 3/8 in. rod (Reynolds 1806), into 36 in. lengths. Bend each length of the center to an angle of 45°. Drill a 1/8 in. hole in each leg of the vee 6 in. from the ends.

Thread a 3/8 x 2 in. eyebolt onto each of the four vees and let it hang at the mid-point.

Mark the fixture box (Universal 56111) around its perimeter at the mid-point between top and bottom. Mark the 90° points around this line with a center punch and drill each point with a 5/16 in. drill. Make sure that the eyebolts remain on the inside of the assembly. Push the vees out far enough to leave about a 6 in. diameter at the center with all of the vees installed. You may find it difficult to get radials started in the holes, but they will go and fit easily when in the final position.

With the ring and radials resting on a flat surface, place the fixture box in the center. Pass the threaded end of the eyebolts through the holes drilled in the sides of the fixture box and run a nut onto each of the eyebolts until one or two threads are visible past the nuts.

The prototype DDRR, a view from the bottom showing details of the hub, mounting flange, feed connection, and tuning condenser.

Slip a washer over each rod tip and push it past the drilled hole toward the ring and install a 1/8 x 3/4 in. cotter pin in each hole. As the work progresses it may be necessary to loosen the nuts at the hub slightly in order to fit the cotter pins and washers.

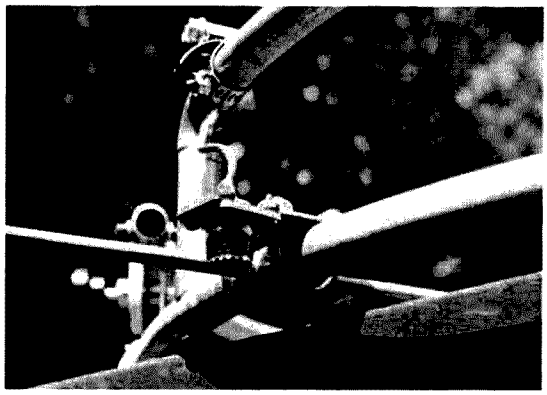
Once all cotter pins and washers are installed, tighten the nuts at the hub until all radials have equal tension and the circle is not distorted. As a check, the visible portion of the threads inside the hub should be nearly equal for all four eyebolts.

If the outer dimensions are critical for your installation, measure 18 in. from the center of the hub along the radials and cut off the excess length. If outer dimensions are not critical, just make sure that all radials are of equal length. The minimum is 18 in. from center. Any greater length, within reason, will provide a slight improvement in operation.

Turn the assembly over and install the pipe flange on the bottom of the fixture box with two ¼ in. bolts and nuts. You will find that two holes in the fixture box align almost exactly with the two holes in the pipe flange when the flange is centered on the box. When these mounting bolts have been securely tightened, install the cover plate (Universal 54-C-1) on the top of the box using the two 10-32 screws which come with the box. This cover will help to keep water from collecting inside the box and thereby reduce corrosion problems. It also adds a professional finish to the job.

The ground plane for your antenna is now complete. It should be rigid enough to be supported on a pipe, threaded into the pipe flange, without sagging.

Attaching the Driven Element

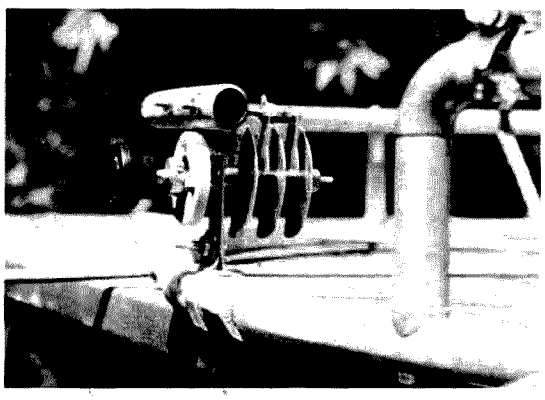


Place the second ring of ¾ in. tubing on top of the ground plane assembly and make any last-minute adjustments necessary to cause the two rings to coincide.

With a tubing cutter or a hacksaw, cut the end of the tubing so that a gap of 3-1/8 in. is left in the upper ring.

If you intend to use the base loading feed system, omit installation of the 90° elbow and its associated parts. Cut the gap in the upper ring to 6 in. and proceed with the installation of insulators. You will have to install a fourth insulator an inch or so in from the gap on the fed end of the ring.

Install the 90° elbow (Reynolds 7832) in one end of the tubing and position it so



that it points downward toward the ground plane ring. The elbow comes with an expandable spring clip which is screwed onto the end of the elbow. This attaching system may be used, but it is preferable to omit it and attach the elbow to the ring by drilling a hole horizontally, through the

A view of the feedline connector attached to the prototype DDRR.

tubing and the elbow to take a 8-32 x 1 in. screw. The latter system insures a good electrical connection at this junction and is a stronger mechanical assembly, less likely to fail after the antenna is erected. This precaution was not necessary on the closed ground plane ring at the joiner, because the tension of the radials serves to hold the joint in solid contact.

Cut a 2-1/8 in. length of tubing from the scrap left over from the rings and slip it

The home-made tuning condenser mounted on the prototype DDRR.

over the remaining end of the 90° elbow. Insert the T-butt connector (Reynolds 7824) in the opening at the lower end of the short piece of tubing.

Position the upper ring over the ground plane ring so that the T-butt connector on the lower end of the elbow assembly is midway between two of the radials. Make sure that the joiner in the ground plane ring is not in a position to interfere with installation at the tuning capacitor, T-butt connector, coaxial connector bracket, or any of the insulators. (See Fig. 1.) Drill a ¼ in. hole straight down through the ground plane ring at the selected point. It is important that this hole be as close to vertical as possible. The T-butt connector may be used as a drilling guide.

Discard the bolt supplied with the T-butt connector and replace it with the 3 in. ¼-20 bolt. This bolt passes upward through the hole in the ground plane ring, through the T-butt connector and the short length of tubing, and engages the threads in the 90° elbow. Tighten this bolt just enough to take all of the slack out.

Carefully measure the distance between the centerline of the upper ring and the top of the lower ring close to the 90° elbow, to insure a 3 in. dimension. If this dimension has not been achieved, remove the short length of tubing and adjust its length accordingly. A good electrical connection at this point is crucial.

Installing the Insulators

Mark a point directly opposite the center of the gap on the upper ring and drill a ¼ in. hole directly downward for the first insulator. Measure around the circumference of the upper ring, a distance of 24 in. each side of the hole for the first insulator. At each of these two points drill a ¼ in. hole directly downward for two more insulators. Mark the corresponding points on the ground plane ring and drill each of these points with a ¼ in. drill.

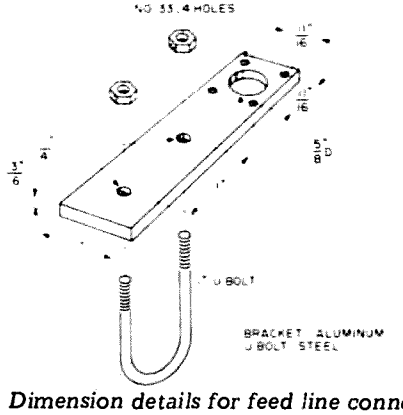
Install the insulators (Smith 2649; Allied 47-C-4357), between the two rings at the drilled points. These insulators are 2½ in. in length, and a 1/16 in. washer must be installed at top and bottom of each insulator to provide the 2-5/8 in.

separation required. Fiber washers sold in plumbing supply houses are ideal here. Once again, a lockwasher under the heads of the 1 in. ¼-20 screws will serve to keep the mechanical structure solid even with vibration caused by wind.

The mechanical construction of your DDRR is now complete. The next operation is to provide for feedline connection and to install the loading condenser.

Installing the Feedline Connector

Cut a length of the 1 in. by 3/16 in. aluminum bar (Reynolds 1821) 2¾ in. long. Drill two ¼ in. holes, ½ in. and 1½ in. from one end and on the centerline. At the opposite end, drill the holes to accept the coaxial fitting (SO-239). (See Fig. 3.)



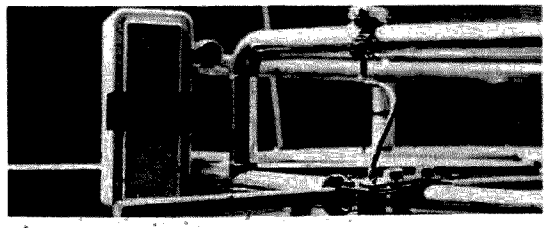


Fig. 3. Dimension details for feed line connector.

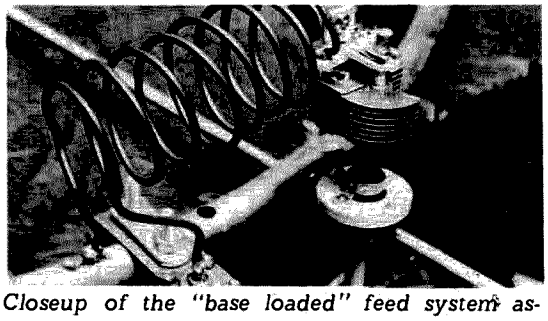
Install the coaxial fitting in the bracket and attach the bracket to the ground plane ring about 4 in. from the junction of the 90° elbow and the ground plane ring. (See photo.) The bracket should be on top of the ground plane straddling the ring and passing through the holes provided in the bracket. When the bracket has been clamped in place, any excess of the threaded ends of the U-bolt should be cut off flush with the top of the nuts. If you are planning to use the base-loading feed system, follow these same instructions, but position the bracket at about the mid-point of the 6 in. gap.

Installing the Tuning Condenser

There are a number of variables affecting condenser installation. These have been discussed in the section on condenser considerations. If you do not intend to use the recommended part, it would be advisable to review that section before proceeding. If you are planning to use the base-loading feed system, you will not need to install a tuning condenser at the top end of the ring. (See the section on alternate feed system.)



The Cardwell ET-30-AD dual-section condenser was chosen as the best component for this application, because it has the low minimum capacitance required; and, with the two sections connected in series, it withstands the high voltage encountered.

Details of the DDRR built in accordance with the instructions in the article. Note the methods of attaching the radials, the feed connections and the box containing the tuning condenser.

Since most antenna installations using the DDRR will involve manual tuning, the condenser has been oriented with the shaft extending downward. This position allows easy access for portable, mobile, or emergency installations. Horizontal positioning may be used and is advisable if motor-driven tuning is contemplated.

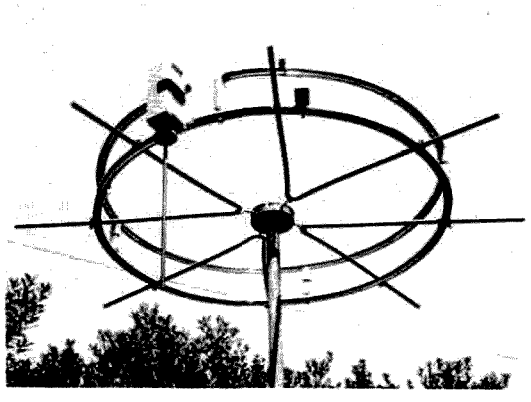
To mount the ET-30-AD in a vertical position with a plastic box for protection, proceed as follows:

Closeup of the "base loaded" feed system assembled on the prototype DDRR.

In one end of the box (Loma 401) drill a 7/16 in. hole on the centerline and 11/16 in. from the inside bottom. Drill four holes 5/32 in. diameter in the bottom of the box to accept the mounting screws which come with the capacitor. These holes must be symmetrical about the centerline, in pairs and on 1-1/8 in. centers. The first pair must be 13/16 in. from the end with large

holes drilled previously. The next pair must be 3-3/8 in. from the first pair and in line with them. On the centerline of one side of the box, drill two holes for 10-32 screws 1 in. from each end. In this last pair of holes, install two 10-32 x 1 in. screws with solder lugs under the head of each screw on the inside of the box. Run nuts onto these screws and tighten them securely. Install the capacitor in the box by slipping the shaft through the large hole in one end and with the mounting bars toward the bottom. Install the four capacitor mounting screws and tighten them securely. Connect a short length of wire from the solder lug under one of the 10-32 screws to the solder lug on the nearest set of stator plates. Connect the other set of stator plates to the other 10-32 screw in a similar manner. The solder lugs for the rotor, at each end of the shaft, must be cut off flush with the ceramic end plates to provide clearance for the cover.

Measure 1¼ in. in from the gap end of the driven ring, that is the end farthest from the feed point. Drill a hole horizontally and on the centerline through the tubing with a #10 drill. Directly below this hole drill a similar hole in the ground plane ring.



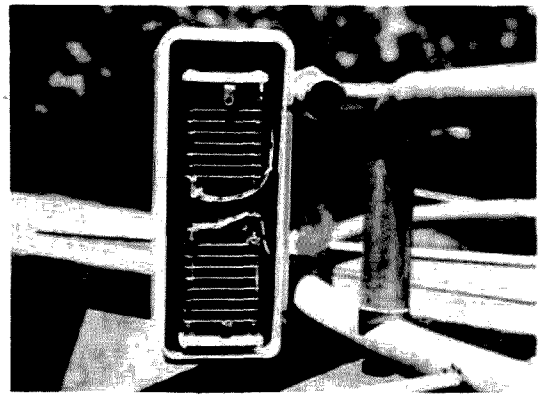
Slip the two 10-32 screws protruding from the side of the plastic box through the two holes in the rings. Be sure that the shaft is pointing down. Using lockwashers and nuts, securely fasten these two points.

Install an insulated shaft coupler on the shaft of the condenser.

There is a base attached to the cover of the plastic box which may be removed. This is the olive green portion cemented to what was originally the bottom of the box and which now serves as a cover. This unnecessary portion can be removed by carefully cutting around the edge with a knife to separate the glued area. The friction fit of the cover should be adequate to hold it in place; but for mobile service, and if the antenna is to be mounted at considerable height, it is advisable to provide some means of locking the cover securely in place. The simplest approach is to wrap the joined edge of box and cover with plastic electrician's tape, which will also provide a degree of weatherproofing.

Connect a 6 or 7 in. length of 1/8 in. flexible braided lead to the coaxial connector in the bracket. Slip the free end of the lead through a ¾ in. pipe clamp installed on the upper ring about 1 in. from the end of the elbow. Tighten the clamp only enough to provide a good sliding connection.

Your DDRR is now ready for tuning.



The final version of the DDRR atop the pipe mast.

Tuning The Antenna

Tuning the DDRR is a relatively simple operation, when done with an swr bridge in the line – and very nearly impossible without one. If you do not own one of these valuable devices, it would be wise to borrow, build, or buy one before attempting the tuning procedure.

With the DDRR supported at least two or three feet above the ground, connect a coaxial cable to the connector on the bracket. Install an insulated shaft on the coupler at the bottom of the tuning con-

A view of the dual section condenser installed in the "butter box" and mounted on the prototype antenna.

denser. Connect the other end of the coaxial cable through the swr bridge to a low-power rf source on the desired frequency. (I used a Globe DSB 100.) The low power is a safety precaution to hold the high voltage hazard to a minimum. With power on, *slowly* adjust the tuning capacitor for minimum indicated swr. With an insulated screwdriver or plastic rod, push the sliding connection at the feed point back and forth until the minimum swr is indicated.

There appears to be a transformer action which occurs between the different diameters of the tubing and the lead from the coaxial fitting by moving the bracket on the lower ring. You should be able to achieve a match with the bracket nearly directly under the contact point on the upper ring. Slight deviation one way or the other from this position will have no significant effect on the efficiency, so any pair of points which provide a satisfactory swr should do. Whatever the end point of the lead is, it should be direct and fairly taut so that it will not shift position later.

There will be interaction between the setting of the condenser and the position of the feed point, so it will be necessary to adjust each one alternately during the tuning procedures. Once a satisfactory swr has been achieved by adjusting the condenser and the feed point, tighten the feedline to the transmitter to be used or increase power to normal operating level and recheck the swr. If the low-power source had the same output impedance as the operating rig, no further adjustment should be necessary. If an unacceptably high swr is encountered, retune the condenser for minimum swr. You should be able to achieve an indicated swr of 1.2:1 with ease. If not, the feed tap must be reset to match the transmitter. This must be done by moving the tap slightly with transmitter power off and checking the resultant swr with power on. It is a bit tedious, but usually a satisfactory setting located in this manner will be good for any antenna location. Once the preliminary adjustments have been made, you should be able to vary the transmitter frequency over a range of ±250 kHz and maintain an swr below 2:1 without resetting the capacitor. By resetting the capacitor, you should be able to maintain an swr close to 1:1 over the entire band.

Erecting the Antenna

The 10m or 15m DDRR antenna constructed as described can be mounted atop a pipe threaded into the pipe flange bolted to the fixture box used as a hub. A length of pipe may be used as a mast or clamped to any existing tower or pole. After the antenna has been raised to the desired height, it will be necessary to readjust the capacitor setting to center the minimum swr on the desired frequency. Once this has been done, the condenser shaft should be locked in place to avoid undesirable movement from vibration. After all adjustments have been made and all mechanical connections secured, it is a good idea to give the entire assembly a protective coating of acrylic to reduce corrosion.

When choosing the permanent location for your DDRR, consider the following factors: Extreme height does not appear to be a significant consideration with this antenna. As with other antennas, it should be located clear of metal objects which might alter its characteristics. Sometimes height is the best way to accomplish this. As height increases so, necessarily, does the length of the coaxial cable. As the length of coaxial cable is increased, the capacitor setting needs to be adjusted to compensate. Therefore the final adjustment of the tuning condenser must be made with the antenna at, or near, the final operating position. This is fairly easy if the antenna is to be relatively close to the ground as in portable or mobile installations. It may become more difficult if the antenna is to be mounted atop a high tower or pole. In this latter case, if it is impossible to do the final tuning in place, one approach is to tune the antenna at the highest possible height and with the full length of feedline connected. If this is done at least one half-wavelength above the ground, satisfactory final tuning adjustment should result.

An Alternate Method of Feeding the DDRR

If the conventional tuning method proves to be too troublesome, or if you

wish to avoid the high-voltage problem, an alternate method of feed is possible.

If we consider the ring radiator as a quarter-wave vertical which is resonant just above the desired frequency, we can feed it as though it were a short vertical whip. In this case base loading lends itself to the mechanical configuration. (See Fig. 4.)

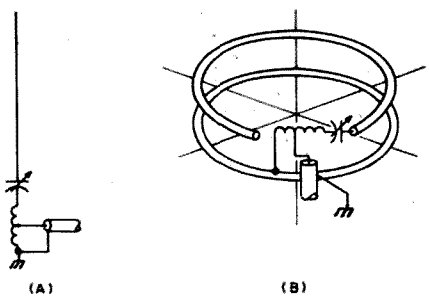


Fig. 4. Comparison between base loaded whip antenna (A) and "base loaded" DDRR (B).

Technical considerations concerning feeding quarter-wave vertical antennas in the manner described can be found in the ARRL handbook in the antenna section. The application of this method of feed to the DDRR is consistent with the electrical principles contained in the reference.

Some modification of mechanical construction is required to incorporate this method of feed for the DDRR antenna described herein. Essentially this amounts to omitting the 90° elbow and its associated hardware and replacing that part of the structure with tuned circuit elements. Mounting of these components must provide for sufficient mechanical strength and also yield the electrical characteristics necessary for proper operation.

The method devised and tested in experiments of W6WYQ is as follows:

Drill a hole horizontally through the upper ring 3/8 in. in from the end. Bolt the rear foot of a 100 pF capacitor (Johnson, Type R, 149-5), with an 8-32 screw through this hole. The capacitor shaft should point downward. Wind a coil of 1/8 in. copper tubing; 7¾ turns, 1-5/16 in. inside diameter, evenly spaced over the 4 in. length. Leave sufficient length at one end of the coil to provide a 1½ in. upright support. Solder a lug to the end of this length and bend it at right angles, in line with the axis of the coil.

Drill a hole downward through the lower ring at a point 2 in. into the gap space measured from the upper end of the fed ring. Bolt the upright support of the coil to the lower ring with an 8-32 screw through this hole. The other end of the coil should terminate at a point very close to the stator connection of the capacitor. A good solder connection should be made between these two points. Attach a length of 1/8 in. copper tubing, or similar size wire, from the coaxial connector to a point ½ to ¾ turns in from the grounded end of the coil. Some experimentation will be necessary to find the exact point for your setup. I matched a 52Ω feedline to this antenna 5/8 turn in on the coil. When mechanical mounting is complete, the gap end of the coil should be bent to re-establish the 2 in. gap prescribed for the 10m DDRR. I found that I could tune the entire 10m band with less than half of the 100 pF capacitor. The standard Type R, with .024 air gap easily handled all that the Galaxy had to offer. If you run higher power, you might need wider spacing. The Type R is available with: .036, .050, .071, and .095 in. air gap. If you must go to wider spacing to handle your power, space might be saved by going to a 50 pF maximum capacitance. Whatever capacitor is used, it should be protected with a weatherproof cover. Since minimum capacitance is not a limiting factor with this type of feed, a minibox should do nicely for the purpose.

Tuning the Base-Loaded DDRR

Tuning procedures are the same as for the shunt-fed system except that the lead from the coaxial connector is moved along the coil until a minimum swr is obtained. We found this point to be 5/8 turn from the bottom end of the coil for RG-8/U.

The advantages of this method of feed are: A narrow spaced capacitor is quite adequate, extremely high voltages are not encountered in the tuning circuit, the system is not highly sensitive to stray capacitance, and the problems of minimum capacitance associated with the shunt-fed system do not apply.

Theoretically, this method of feed should be less efficient than the shunt-fed method. This may be true for the long haul, poor conditions, DX work; however, no significant difference could be detected between the two antennas under normal operating conditions.

Expanding Band Coverage

One of the advantages of the DDRR is its high-Q characteristics, which greatly reduce noise and help to minimize interference. Unfortunately, these characteristics limit the band coverage of a fixed-tuned DDRR. This shortcoming can be circumvented by providing some means of remotely adjusting the capacitor. This consideration applies to both the shunt-fed and base-loaded feed systems. If the antenna is to be mounted close to the operating position an extension shaft is all that is required. In some installations, chain drives, pulley and cord, or other mechanical linkage can be applied. By far the most satisfactory arrangement is a low-speed reversible motor geared to the capacitor's shaft. There are numerous reversible motors available on the surplus market which would be suitable for this purpose. Since no specific unit is identifiable, no detailed installation instructions are included here. However, certain general precautions must be observed when installing any motor. To begin with, if the motor is to be installed close to the capacitor, which is the most logical location for it, the motor windings are in a strong rf field. To minimize the effects of this environment, the motor should be mounted directly to the ground plane ring and bypass condensers installed on the leads to the motor as close as possible to the grounded case. Leads to the capacitors should be as short as possible. The power lead for the motor should come away from the antenna as nearly as possible to a right angle with the ground plane for a distance of one-half wavelength. A well grounded shielded cable would be an advantage, but is by no means mandatory. There is no requirement to incorporate a selsyn indicator in the system as the minimum swr indication is all that is required.

Capacitor Considerations

It is anticipated that many who read this article will wish to make modifications to the design to incorporate their own ideas or introduce improvements. Some will also wish to press into service some of the junkbox components they have on hand but which do not conform to the specifications in this article. Most aspects of the mechanical construction allow for fairly wide deviation; however, there are some restrictions on the type of capacitor which is suitable for the DDRR which limit the selection severely. I discovered these by the age-old method of trial and error, with the latter leading all the way. To save the adventuresome experimenter from frustration, these considerations are included here. Most of the limitations mentioned pertain to antennas for 20 MHz and above. The lower frequency antennas require more capacitance for tuning and a little stray capacity has less effect on the overall circuit. The high voltage problem, however, seems to be more aggravated on the lower frequencies.

In my experiments I first used a single-bearing capacitor similar to the E. F. Johnson Type M with .017 in. spacing. While the capacitor was completely satisfactory in terms of minimum capacitance, it arced at rf power levels above about 300W. I tried substituting a glass-insulated piston trimmer with about 1/32 in. glass walls, which arced at 400W. Next, I went to a wide-spaced unit (Bud 1543), with a .175 in. spacing. This capacitor withstood the voltage easily, but even in the fully open position, the antenna system would not resonate above 26 MHz. (It was at 29 MHz with the other components installed.) The cause of this was determined to be the high minimum capacitance caused by the large metal end bearing plates which were a little over 2 in. apart and with an area of about 4 sq in. I had on hand a Cardwell NG-35-DS which was of similar construction to the Bud unit but with end plates spaced 4 in. apart. This, too, proved to have too much capacitance, even at the minimum setting. I then found that the Cardwell ET-30-AD, specified here for the 10m unit, was entirely

satisfactory. This condenser has ceramic end plates and the minimum capacitance is well within bounds. Plate-to-plate spacing is 1/16 in. and connecting the two sections in parallel gives an effective plate spacing at 1/8 in., which is adequate for the 500W maximum power used. Wider spacing might be necessary if higher power is applied. Although the ET-30-AD was satisfactory in electrical operation, it is a little long for the installation. I hoped to find a capacitor which would fit between the two rings. Finding no suitable unit listed in the manufacturer's catalog, I manufactured one. The plates were removed from a National capacitor of similar construction to the Bud and Cardwell units which were rejected. The National capacitor was tried and rejected also, but the stator and rotor plates were mounted on shafts with a bolt and spacer arrangement which made it ideal as a source of parts. With the parts from this capacitor, a capacitor was assembled directly onto the antenna. The stator plates were bolted to the driven ring and the rotor mounted to a bearing attached to the ground plane ring by a bracket. The plates, two stators, and three rotors were spaced to about ¼ in. This arrangement seems to be the most satisfactory all around, since it not only withstands the voltage, but also fits within the limited space. This method has not been prescribed in this article because of the additional mechanical construction involved and because of the difficulties in providing a weatherproof housing for it. It is described here because it may well be that those running full legal power may have to resort to this approach in order to make the antenna work at those power levels. Of course it is not necessary to dismantle an old capacitor for parts. Suitable plates may be cut from stock. Those I used had an area of about 2 sq in.

If you have an old disc-type neutralizing capacitor (Millen 15011) this can be made to work. It is particularly well suited to fixed-tuned applications but can be used as a variable with proper linkage.

If you are only interested in fixed-tuned systems, by far the easiest solution to the capacitor problem is to install a length of coaxial cable between the two rings with the shield connected to the ground plane and the center conductor to the driven element. I found that 2-5/8 in. of RG-8/U tuned the 10m antenna to 29 MHz.

DDRR Antennas For Other Frequencies

Details for construction of the 10m DDRR described herein are suitable for frequencies down to 21 MHz. Above 30 MHz, sheet metal or screen ground plane surfaces are more easily fabricated. Smaller tubing sizes recommend copper, and soldering techniques replace pipe clamps and U-bolts. Those who wish to use this antenna on 6 or 2m would do well to review the article by G. W. Horn I1MK, in the September 1967 issue of CQ.

The general construction details described above for the 10m DDRR are applicable to lower frequency units, but below 21 MHz. The method of making and attaching the radials requires some modification. The V-shaped radials of ¼ or 3/8 inch aluminum rod do not provide adequate mechanical strength, and there is some doubt as to their electrical efficiency when used in conjunction with the larger size tubing. Moreover, a larger number of radials should be used to improve both electrical efficiency and mechanical strength. Obviously the small utility box used as a hub would not be adequate on these large antennas.

We tried several methods of making radials for the 20m antenna and finally adopted the following system as most suitable. (See Fig. 5.)

The hub on this larger antenna is a disc of aluminum ¼ in. thick and 12 in.

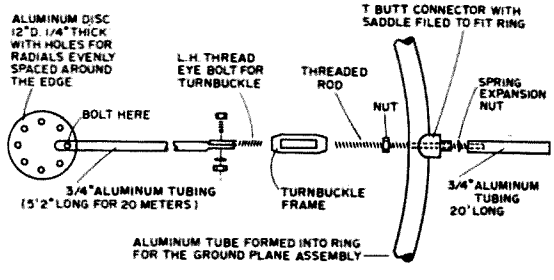

Fig. 5. Assembly technique for DDRR ground plane radials for 20 and 40 meter antennas.

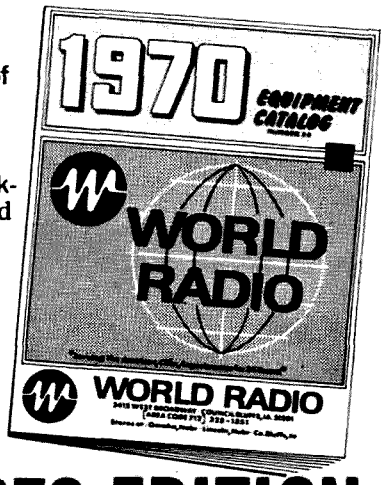
diameter. The radials are ¾ in. aluminum tubing. The inner portion of each radial is 5 ft 2 in. long. A 1¼ in. section on each end of these radials is flattened and a ½ in. hole drilled through the flat part one inch from the ends. Radials are bolted to the edge of the aluminum disc, at about 3 in. intervals. The left-hand-thread end of a 6 in. turnbuckle is bolted to the opposite end of each radial; 20 in. lengths of ¾ in. tubing are mounted around the outer perimeter of the ring. These stubs are attached using T-butt connectors with the bolt replaced with a length of ¼-20 threaded rod with a nut run on it to cinch it up against the ring. The right-hand-thread-end of the turnbuckle is run onto the rod; then, by turning the turnbuckle, tension can be applied to each rod in turn. The whole assembly presents a neat appearance and is quite strong enough for pole mounting, although we added 3 legs from the midpoint of 3 radials down to the mast to provide more stability.



Performance

The 10m DDRR as described in this article has been in use at W6WYQ for about 4 months. On-the-air checks show its performance to be equal to that of a standard isotropic radiator mounted on the roof. The DDRR has been handicapped by being located variously: on a box in the middle of the garage, in the rafters of the garage, on the roof, on top of the car, and even resting on the ground. In spite of this, solid contacts have been made with W1s, W4s, VE7s, and many stations in between. The DDRR doesn't compete with the multielement beams, but it seems to be right in there with the verticals. It has shown itself to be superior to the multiband trap-type verticals. Most of the best contacts have been made with stations using verticals or quads, which is, no doubt, the vertical polarization of the DDRR antenna being demonstrated. The sharp tuning characteristic markedly reduces QRM and noise, and that aspect has been quite enjoyable.

The 20m DDRR is presently undergoing evaluation at another station. Initial tests indicate that its performance is very similar to that of the 10m version. . . . W6WYQ ■

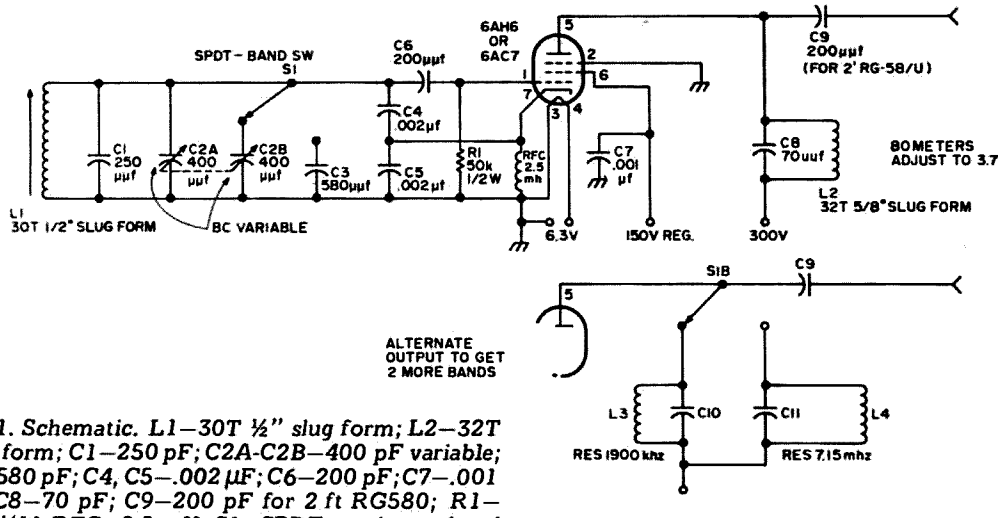
VFO CIRCUIT

Horton Presley KØHVK
1126 S. Hickory
Ottawa KS

If you want a stable, simple vfo for 80 and 40 with full bandspread on both bands and possible 20 meter usage with bandspread on about 2/3 of the dial, read on. This is basically the rig from *GE Ham Tips* of March-April 1959 without the complicated inductance and capacitance switching which is used there to get full bandspread on all bands.

This unit starts at 160 then doubles in the plate circuit to come out on 80. Switch S1 (Fig. 1) cuts out C2a and inserts C3 in order to give full bandspread when doubling in your transmitter to 40. Depending on the slug-tuned form you used and the BC capacitor, you may have to juggle the turns of L1 and possibly C1 to get full 1.75-2.0 coverage, and C3 may be somewhat different



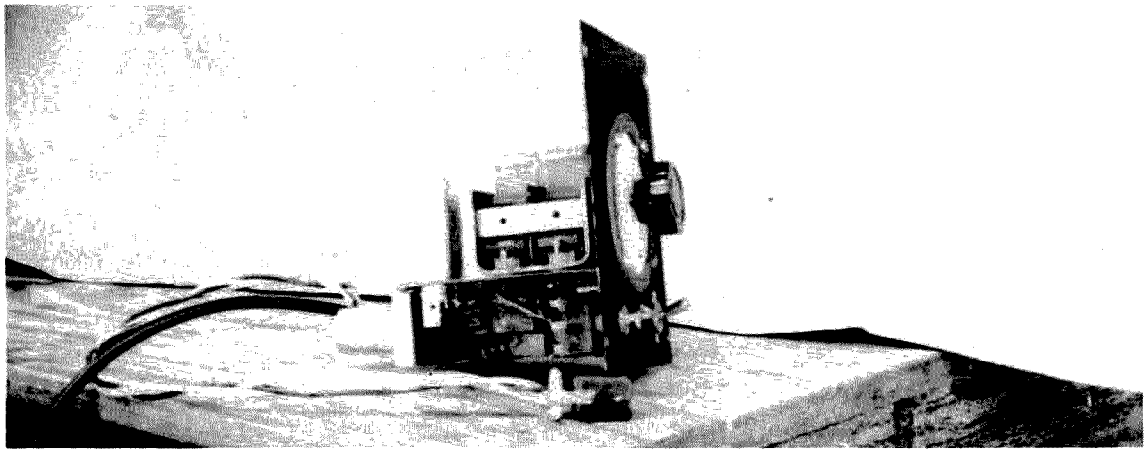


Fig. 1. Schematic. L1—30T ½" slug form; L2—32T 5/8" form; C1—250 pF; C2A-C2B—400 pF variable; C3—580 pF; C4, C5—.002 μF; C6—200 pF; C7—.001 μF; C8—70 pF; C9—200 pF for 2 ft RG580; R1—50K ½W; RFC—2.5 mH; S1—SPDT toggle sw—band sw.

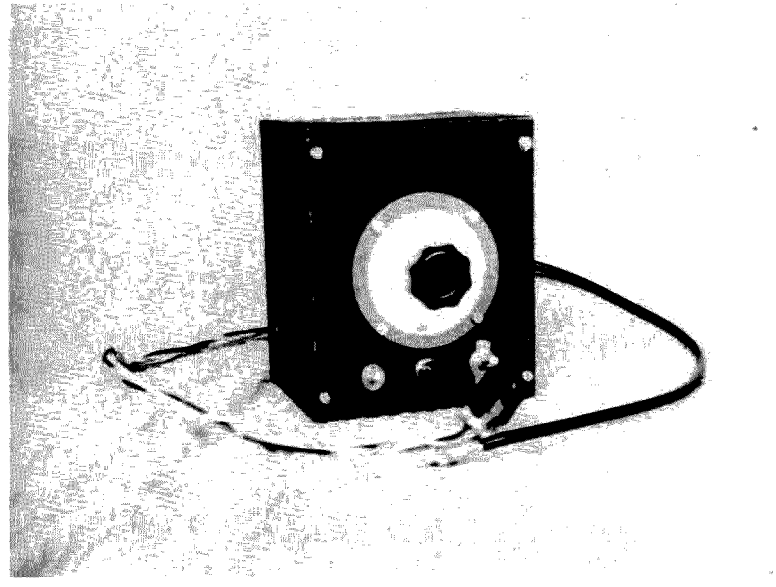
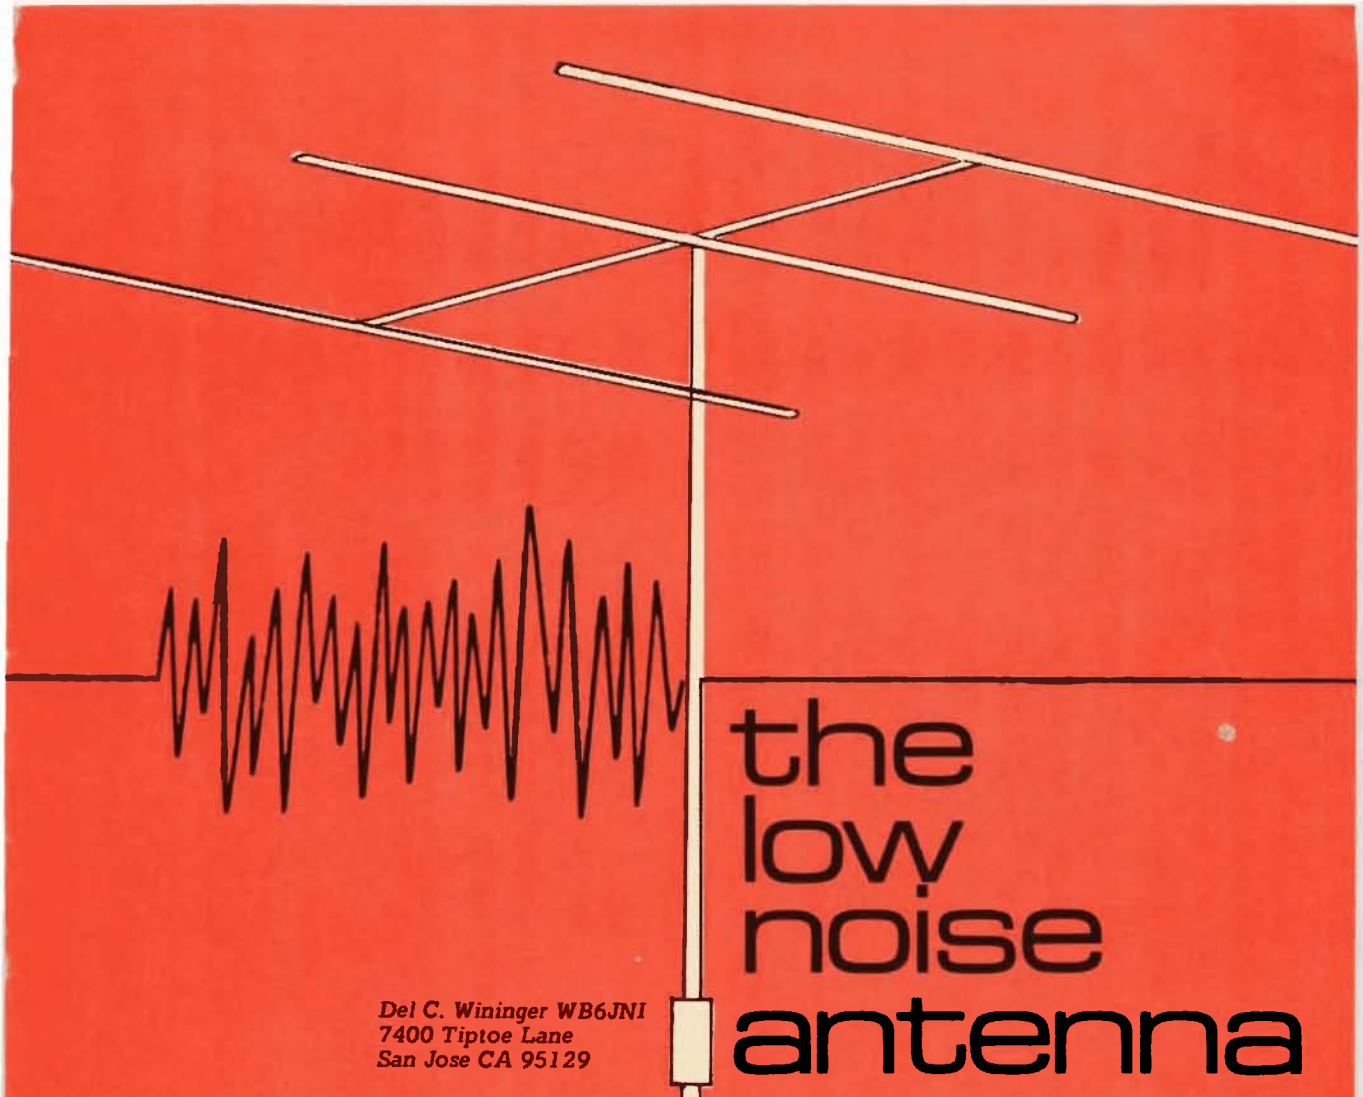
As this view of the unit with its cover removed shows, the vfo can be attractively packaged within a very small volume. Power is furnished to the unit from the transmitter. If no "external power" connector is provided on the transmitter chassis, it can normally be installed with little effort.



from mine in order to get full bandspread on 40.

The fixed condensers I used were ordinary micas from the junkbox. Probably as a consequence, the vfo takes about 15 or 20 minutes to settle down where it will stay zero beat with a BC221. I know that I should spend a couple of bucks for zero or negative-temperature-coefficient ceramics so that it will not drift more than a hertz or two from a cold start, but my old much-chopped-up National 100X takes that long or longer to settle down, so what good is it to have a vfo that stabilizes faster? Obviously though, the better the fixed condensers you use, the better the stability.



This is my first vfo project and if the same is true for you, take heed! *Don't* put a pilot lamp right under the confounded main tuning capacitor! It sure makes a nice looking, symmetrical front panel, but does it ever play hob with drift! Also, keep all tube heat away from L1. I put the tube on the back, outside the case.

One further suggestion you may want to try: Make S1 a DPDT unit and follow the suggested alternate output circuit. Make L3-C10 tune 160 meters and L4-C11 tune 40. This will give a 160 meter output in addition to the former 80 and 40, and better 20 meter usage than is the case with the simpler circuit (since you will be only doubling to get to 20 instead of quadrupling).

. . . KØHVK ■

What's wrong with this picture? The pilot lamp has been installed immediately below the tuning capacitor. The glowing lamp looks great when the vfo is in use, but the heat of the lamp does interesting things to the frequency of operation.

the low noise antenna

Del C. Wininger WB6JNI
7400 Tiptoe Lane
San Jose CA 95129

The hypothesis of antenna reciprocity—that is, a good transmitting antenna is a good receiving antenna — is only conditionally true. A tuned antenna will give you a signal that is twice as loud as an untuned antenna, but it may have four times the noise. The controlling factor in the noise transfer is the impedance match. For efficient transmission of power, the reflected antenna impedance must match the transmitter output impedance. But, "...the best receiving noise figure is usually obtained with some degree of mismatch between the receiver and the antenna." The quote is from S.N. Van Voorhis, MIT Radiation Series Volume 23.

I found this out experimentally while looking for a better signal. I have two antennas, a 13 ft vertical for the receiver, and a balun-fed three-band inverted vee for the transmitter. The transmitting antenna is trimmed to an swr of 1.5:1 in the middle of the CW section of each band and pushes 40W very nicely.

Bearing in mind the adage that says you can't work 'em if you can't hear 'em, I put the transmitting antenna on the receiver. Although the signal was twice as loud, the noise was almost impossible to work through—I heard it, but I didn't believe it! Then I did a little research.

The signal-to-noise figure is dependent upon a poor match for the noise and a better match for the signal. This can be obtained at the expense of signal gain, but most receivers have plenty of gain to spare.

There are a large number of variables in any working system and one cannot say that any specific fix will lower your signal-to-noise ratio; but at least now you know that it is possible to improve the situation by experimenting. Just remember that the loudest signal will not necessarily be the most readable. ...WB6JNI ■

John J. Schultz W2EEY, 1829 Cornelia St., Brooklyn NY 11227

REMOTE SWR INDICATOR

Conventionally placed swr meters often do not indicate the true swr at the transmission line/antenna junction. Remote location of the reflected power sensing portion of an swr unit is the key to true swr value indication.

Rather than using a combined swr indicator and sensing unit in the transmission line by the transmitter, there is a great advantage to placing the swr *sensing* unit at the junction of the transmission line and the antenna. For one thing, the true swr would then be shown on an *indicator* placed by the transmitter rather than an swr reading which depends upon transmission line attenuation characteristics. Also, one would have a means of checking the condition of the transmission line continuously, all the way to the antenna termination.

The constructional problems in placing the sensing portion of an swr unit at the far end of the transmission line have prevented most amateurs from building a remote-type swr meter. A separate enclosure must be used for the sensing unit which adds additional weight at the antenna. Generally, this would be no problem with a beam antenna where the boom can be used to support the necessary enclosure. However, such an enclosure could cause quite a droop in the center of a thin wire antenna. Another problem is transferring the output from the sensing unit to the indicator unit at the transmitter, unless a separate wire pair is used for this purpose.

Most of these problems have been overcome in the simple experimental swr unit described in this article. The unit described was constructed for use in a 300-ohm twinlead transmission line, but the techniques used are applicable to other impedance transmission line systems. Some minor problems that are noted later arose because of the particular antenna system in which the unit was tried, but the basic validity of the construction and circuitry used was established.

Basic Units

Figure 1 shows the arrangement of the swr sensing and indicator units in the transmission line. The sensing unit is a

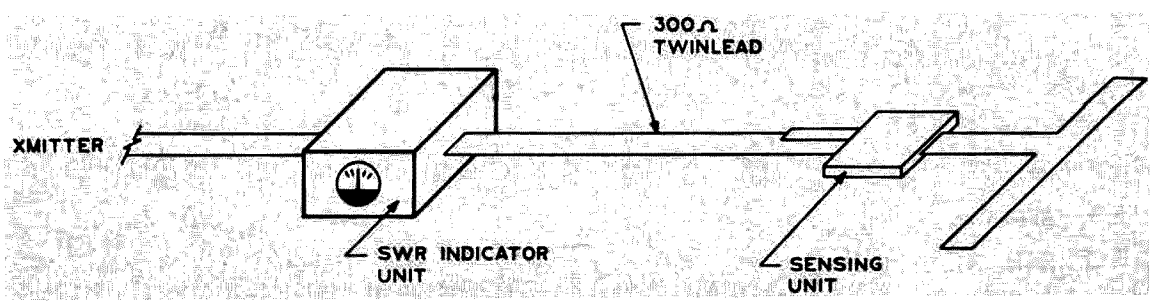


Fig. 1. Basic setup of components used in the remote swr monitoring unit.

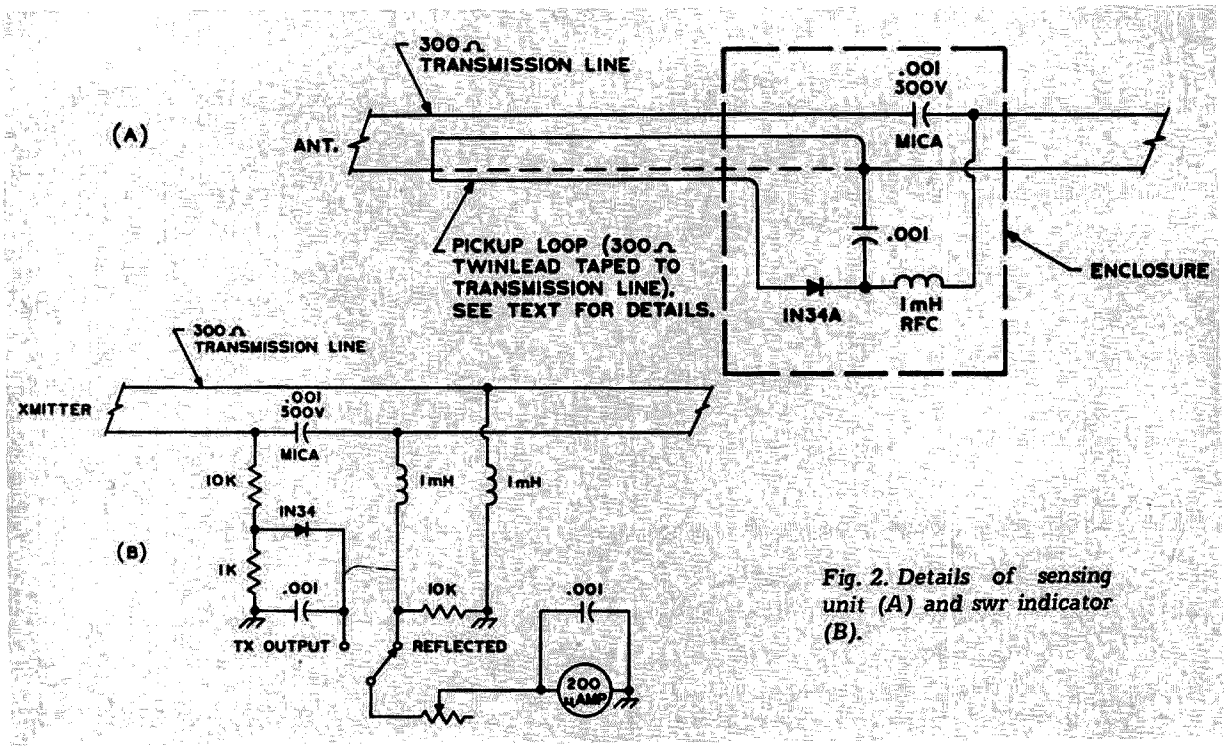

Fig. 2. Details of sensing unit (A) and swr indicator (B).

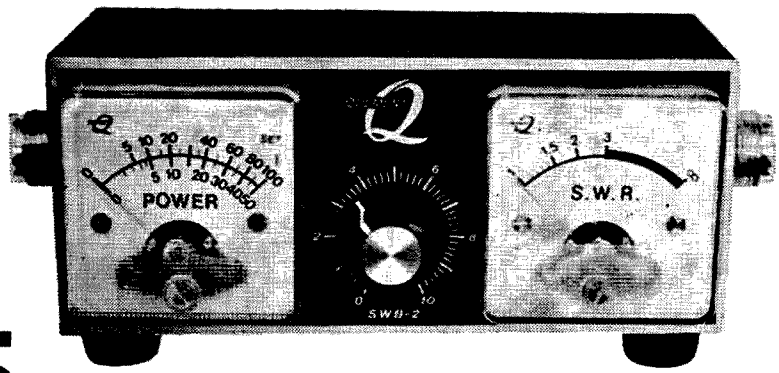
modified form of the old twin-lamp swr indicator for twinlead transmission line but arranged to only respond to reflected power pickup. The indicator unit functions as a combination rf voltmeter to indicate the relative power output of the transmitter and as an indicating dc voltmeter for the reading of a dc voltage generated by the sensing unit which is proportional to the swr. The connection between the two units is via the same transmission line between the transmitter and antenna. The same line can be used simultaneously for both purposes since the rf power flow and the dc voltage generated by the sensing unit can flow on the same line but then be separated by appropriate capacitor and rf choke combinations. This feature is indicated more clearly in Fig.2(A) and 2(B) which show the details of the sensing and indicator units.



The sensing unit consists of a length of 300-ohm twinlead identical to that used for the transmission line. The assembly is taped onto the transmission line. One end is terminated in a short. A small rectifier/capacitor unit is placed at the other end where a pilot lamp would normally have been placed in the old "twin-lamp" swr indicator. The dc voltage generated is placed on one side of the transmission line via the rf choke. The dc blocking capacitor prevents a dc short circuit path from existing via the antenna (a folded dipole, for instance). The dc voltage, then, which is proportional to the reflected power level at the transmission line/antenna junction is transferred along the transmission line to the transmitter as a dc voltage difference between the two transmission line conductors.

At the indicator unit, a dc ground reference is established via an rf choke to ground for the side of the transmission line directly connected to the sensing unit pickup loop. The rf choke and blocking capacitor in the other side of the transmission line perform the same general function as in the sensing unit, only this time the capacitor is used to prevent a dc short between the transmission line conductor via the transmitter output circuit. A resistor voltage divider network and rectifier circuit on the transmitter side of the blocking capacitor provide a dc voltage proportional to the transmitter output level. The meter is switched between reading this voltage and that transferred along the transmission line from the sensing unit. The variable resistor in series with the meter allows the meter to be adjusted to a "set" value before being switched to read swr. However, the operation and meaning of the "set" reading is

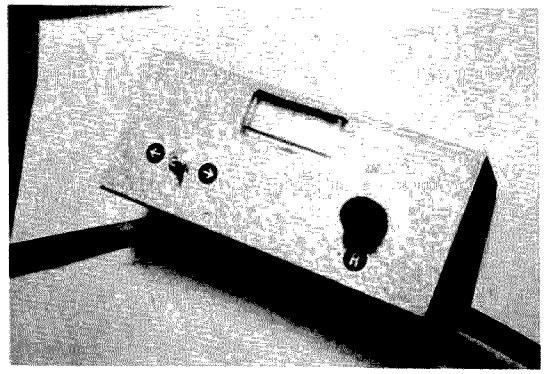
quite different from that of the usual swr meter. The differences, which are explained later, should be well appreciated.

Construction and Adjustment



The use of the swr indicator was mainly checked on 40 and 20 meters. The length of twinlead used as the pickup loop was taped to the transmission line. The components shown in Fig.2(A) were compactly assembled in a plastic snap-open box measuring about 2 x 1 x 1 in., which was acquired as the result of some now unknown purchase. However, almost any similar lightweight enclosure would suffice. Particularly when dealing with coaxial transmission lines, it would be advisable to also use a shielded enclosure instead of a plastic unit in order to preserve the continuity of the outer shield. With some care in construction, it would seem to be perfectly feasible to use the smallest minibox available for this purpose (Bud CU3000A).

The indicator unit, as shown in the photograph, was assembled in a Bud CU-2103A enclosure. Most of the components were mounted on a 6-lug terminal strip to which sections of twinlead going to the transmitter and antenna were also connected. Before soldering to the terminal strip, the twinlead sections were passed through access holes drilled in the mating part of the minibox enclosure. The toggle switch and potentiometer used were special miniature types and, therefore, appear quite small in relation to the other components. Regular size components can, of course, be used and there is more than ample space for them in the enclosure specified.

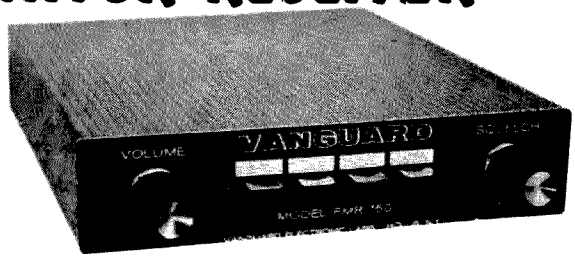
After connection of the sensing and indicator units in a 50 ft transmission line, the far end of the line was terminated in a 300-ohm dummy load and the line swr checked using a conventional swr meter. This was done to verify that the rf chokes used in the sensing and indicator units did not upset the line conditions. Although the chokes should present a reactance of some 40 kΩ on 40 meters, it is possible that some odd resonant condition might affect their performance on a specific band. The swr was found to be essentially 1:1. Next,

All components are assembled on a terminal strip or wired between it and the panel components in the swr indicator unit. IN34 diode is shown connected between terminal strip and switch on right side. Panel unit on left is miniature potentiometer.

Front view shows simple controls arrangement. Meter scale must be calibrated for various swr readings as described in text.

while using a transmitter with about 50 watts output, the "set" potentiometer in the indicator unit was used to obtain a full-scale meter reading with the switch set to measure the relative transmitter output. A deliberate swr of 2:1 was then introduced by substituting a 150-ohm resistor for the 300-ohm dummy load. The switch in the indicator unit was set to measure the reflected power and the pickup piece of twinlead connected to the sensing unit – extended as necessary to produce about a .2 reading on the meter's 0–10 relative scale. About 2½ ft of twinlead was required. The same procedure was followed using other resistors, as available, to simulate different swr indications. Of course, the length of the twinlead pickup piece cannot be changed once established. One has to accept the relative reading that results on the meter scale for various swr measurements (or make a new meter scale). Also, during the calibration of the scale for swr, the potentiometer setting should never be changed.

The above procedure calibrates the indicator unit for a particular set of conditions – transmitter output, frequency, and transmission line length. Once calibrated, the swr unit can only be used under different conditions with some reservations. The calibration will remain correct for a range of transmitter powers, the same as a conventional swr meter. The potentiometer in the indicator unit is used in the same manner to "set" the meter while reading the relative transmitter output. The calibration will not remain correct over a very wide frequency range since the pickup proportional to reflected power will not vary in the same manner as that used to measure the relative transmitter output – unlike the action in a conventional swr meter. The calibration will generally remain correct over two bands and the scale can, of course, be specifically calibrated on any band. The calibration will also be affected by any major change in the transmission line length due simply to change in ohmic resistance affecting the transfer dc flow from the sensing unit.



Practical Results

The swr unit described in this article was developed as an experimental idea and it was not expected that it would work in practice the first time without some flaws. Actually, the test results with an antenna were surprisingly good. Used with an antenna that had previously exhibited essentially a 1:1 swr with a 50 ft twinlead transmission line, the indicated swr using the remote swr system was about 1.5:1. This difference in swr reading probably was due to "antenna current," since the transmission line could not be run away exactly at right angles from the center of the antenna. Also, using a shielded enclosure for the sensing unit might have helped. As best as it could be done, various discontinuities resembling transmission line faults

VHF FM MONITOR RECEIVER

Only $79.95 Postpaid in the U.S.A.

100% MADE IN U.S.A.

The new **VANGUARD FMR-150** is not just another frequency converter but a complete FM receiver with outstanding performance.

Check the following features and see why it's the best. Collins IF filter for separating those closely spaced stations you hear together on other sets● Double conversion to eliminate interference from image frequencies● Dual Gate MOSFET RF stage for low noise. .2 uv. sensitivity, and minimum cross modulation● Automatic squelch for eliminating noise● Self-contained speaker● Operates on 12v. D.C. negative ground● Heavy gauge anodized aluminum case 6" x 7" x 1-3/8"● Provision for 4 crystal controlled channels at the push of a button● One channel of your choice supplied with receiver. Additional channels available just by plugging in another crystal at $4.95 ea. No need to buy another RF unit as in some other sets● Factory tuned to cover any 6MHz segment from 135 to 175 MHz.

HOW TO ORDER: The **VANGUARD FMR-150** is available only direct from our factory. Include remittance in full plus sales tax if you reside in N. Y. Be sure to state the 6MHz segment you will want to cover and the exact push button frequencies to be included.

VANGUARD LABS Dept. H, 196-23 Jamaica Ave., Hollis, N.Y. 11423

were created. The faults were reflected in the readings observed on the indicator unit – a situation which would not occur with a fairly long transmission line. Some of the faults created were observed on the indicator unit as even a slight improvement in swr – as when metal foil was wrapped around portions of the transmission line or antenna to simulate dielectric condition change. But, the foil probably acted in some manner to improve matching conditions, such as a stub would. The important thing is that changes in the transmission line or antenna condition were indicated. Drastic faults such as an open conductor were clearly indicated by a high rise in the swr on the indicator unit.

Summary

There are many refinements that could be incorporated into the swr unit as described. Nonetheless, the type of swr monitoring scheme demonstrated is a definite advance over conventional ones.

Ideally, it should be possible to place a sensing unit at the far end of the transmission line which would transfer back near the sensing unit and antenna faults *over the transmission line* voltages proportional *both* to the forward and reflected powers at the sensing unit. Then, one should be able to monitor independently the transmission line condition and the swr existing at the very termination of the transmission line. One could build a suitable sensing unit if two independent dc paths from the sensing to the indicating units were available. The only simple solution to this problem would seem to be the use of a shielded balanced transmission line, either 70 or 300 ohms impedance. More sophisticated, time-sharing current flow schemes over a two-conductor transmission line are certainly possible, but their reliability and economy might not make the total effort worthwhile. The incorporation of a dc amplifier in the sensing unit, which could be of the Monimatch type, would also allow the construction of an extremely compact sensing unit. It could easily be rf powered directly from the transmission line current flow.

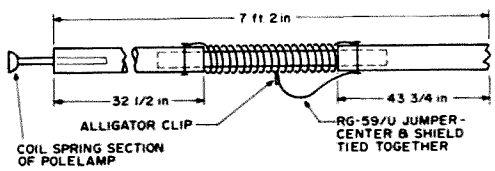
Bossier City LA 71010

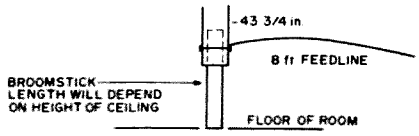
The Little Wonder: MARK II

While in college this past school year we designed the "Little Wonder" antenna described in *73* Magazine of May 1969. This article brought a flood of mail from amateurs all over the world. Moving from the college dorm back to my permanent home the "Little Wonder" for the most part was discarded in favor of the "Skeleton Cone Antenna" which appeared in *73* Magazine, August 1969. The reader will quickly note the simplicity of the "Little Wonder." The "Little Wonder: Mark II" has the same simplicity, but two added charms: (1) its appearance is more attractive with its scant 7 ft stature; and (2) more important, it has a strong radiation characteristic which is a benefit to any ham on today's crowded bands.

For those who missed the original article of *73*, May 1969, a bit of a review is in order. Two pieces of hard-drawn ¾ in. copper tubing 43¾ and 31½ in., were connected via a coil which was 197 turns of 12 AWG Nyclad close wound on a wooden dowel. The unit was end-fed with a single feeder to an L network or Viking Matchbox and tuned for 1:1 swr.



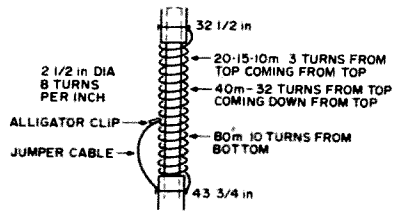
The *Mark II* uses the basic concept of the original "Little Wonder" antenna with four exceptions: (1) the hard-drawn copper tubing is now two sections from a discarded polelamp stand; (2) the low-Q 197 turns of Nyclad wire is now a high-Q BW 3034 coil stock, 2½ in. diameter (8 turns per inch and 135 mH; (3) the *Mark II* is tapped for the band being used; and (4) the antenna can stand anywhere in the room due to the polelamp construction concept.



Construction is simple and all parts can be purchased or scrounged:

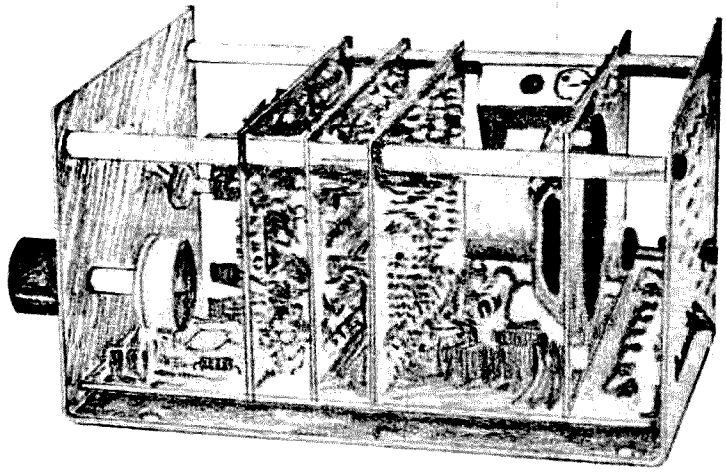
1 used polelamp or spring-type stand
2 "bar stool" rubber feet
1 BW 3034 coil stock or equivalent (2½ in. dia, 8 turns per inch)
3 6/32 x 1¼ bolts and nuts
1 3 ft dowel rod or an old broomstick
1 alligator clip
1 8 ft single-wire feedline to run from the Mark II to the antenna tuner.

How to construct. The pole stand is cut in two pieces, one 43¾ in. and the second 31½ in. Before cutting the 31½ in. section, press the spring section until the tension is



tight. When the spring section is depressed *then* measure for 31½ in. The two sections of the pole stand are connected together via a 1 in. wooden dowel rod or broomstick. The two metal poles are spaced 10 in. apart to accommodate the coil stock. A small hole is drilled in each pipe and dowel so the poles will not slip together and provide for a mechanical and electrical connection for the coil. A second dowel rod is placed in the opposite end of the pole from the spring coil section. The length of the dowel will be determined by

the height of your ceiling. A standard 8 ft ceiling will require a 14 in. dowel. The 8 ft single feedline is connected to the *Mark II* at the same point in which the 14 in. dowel is attached to the pole stand. A jumper wire with an alligator clip attached to the bottom of the coil end is used to short out part of the coil, depending on what frequency you are operating. For 75 meters, the coil is tapped 10 turns from the bottom; 40 meters is tapped 32 turns from the top; and 10 meters are all 3½ turns from the top. The use of an swr bridge and a field strength meter will determine the specific tap for each for each location. Both the east and west coast have been worked on 75 and 40 meters on both a barefoot KWM-2 and the KWM-2 with the SB200.



The *Mark II* is tuned in the same manner as the original *Little Wonder*. The equipment is first tuned into a 50Ω load and then connected to the antenna tuner. (Do not tune the rig.) The antenna tuner is tuned for 1:1 swr utilizing 275W Viking Matchbox or L network.

I trust the apartment dwellers will try the *Mark II* and find hamming is still the best hobby of them all.

. . . W5ZBC ■

WITH THE ORD DK-1 CW CAN BE FUN

Disenchanted with CW? Is the code too old a mode for you? If so, you might be an ideal candidate for ORD's DK-1 digital keyer, a fantastic little package with a brain inside. Believe it or not, the ORD actually makes it fun to send CW.

If you're already sold on CW but haven't yet tried the DK-1, by all means stop in at your nearest radio store and give it a go. This unit is nothing short of fantastic!

With a built-in memory and "interchange" circuitry, the DK-1 "remembers" which paddle was pushed last, even when both the dot and dash keys are activated at the same time. This feature minimizes errors that might otherwise be caused by an operator's inadvertent keying of the wrong paddle.

It shouldn't take long to achieve proficiency on CW with the DK-1, though you may never be able to utilize the full capability of the keyer: a breathtaking 60 wpm. A panel knob allows smooth and continuous adjustment of sending speed all the way down to 7 wpm.

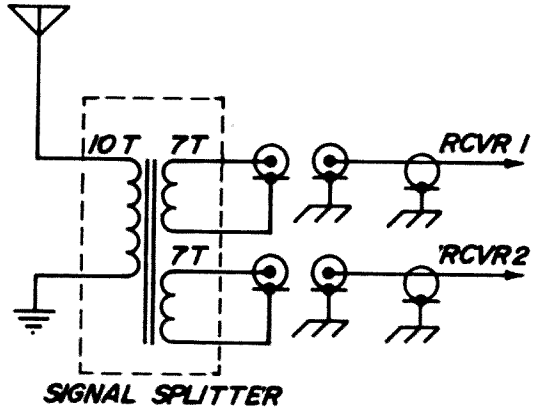
Regardless of code speed, the spacing of and between digital pulses remains at a constant ratio, with the dashes always exactly three times the duration of the dots.

An engineer looking at the guts of the DK-1 might well mistake it for a modern missileborne package. That same high-density, modular-construction approach used in the aerospace industry is employed in the assembly of the ORD keyer. With cover removed, the unit resembles a "card rack"; three circuit cards and the monitor speaker frame are stacked vertically over a "mother board," which contains a transistor-regulated power supply.

The paddle assembly is not included in the purchase price ($130) of the DK-1. To be compatible with the electronics, the mechanical portion must be a dual-contact paddle set. A conventional keying mechanism would also be a handy "extra" for the paddle assembly, since the DK-1 can be keyed on a "manual" as well as "automatic" basis.

The Brown Bros. key set is an ideal choice for the DK-1. It contains precision-machined, adjustable speed paddles as well as an adjacent standard key, all mounted on an extra-heavy cast metal base. Terminal boards on the rear underside of the mechanism make interconnection to the DK-1 a snap.

All in all, CW's a ball, 'cause the DK-1 makes "sending" fun!



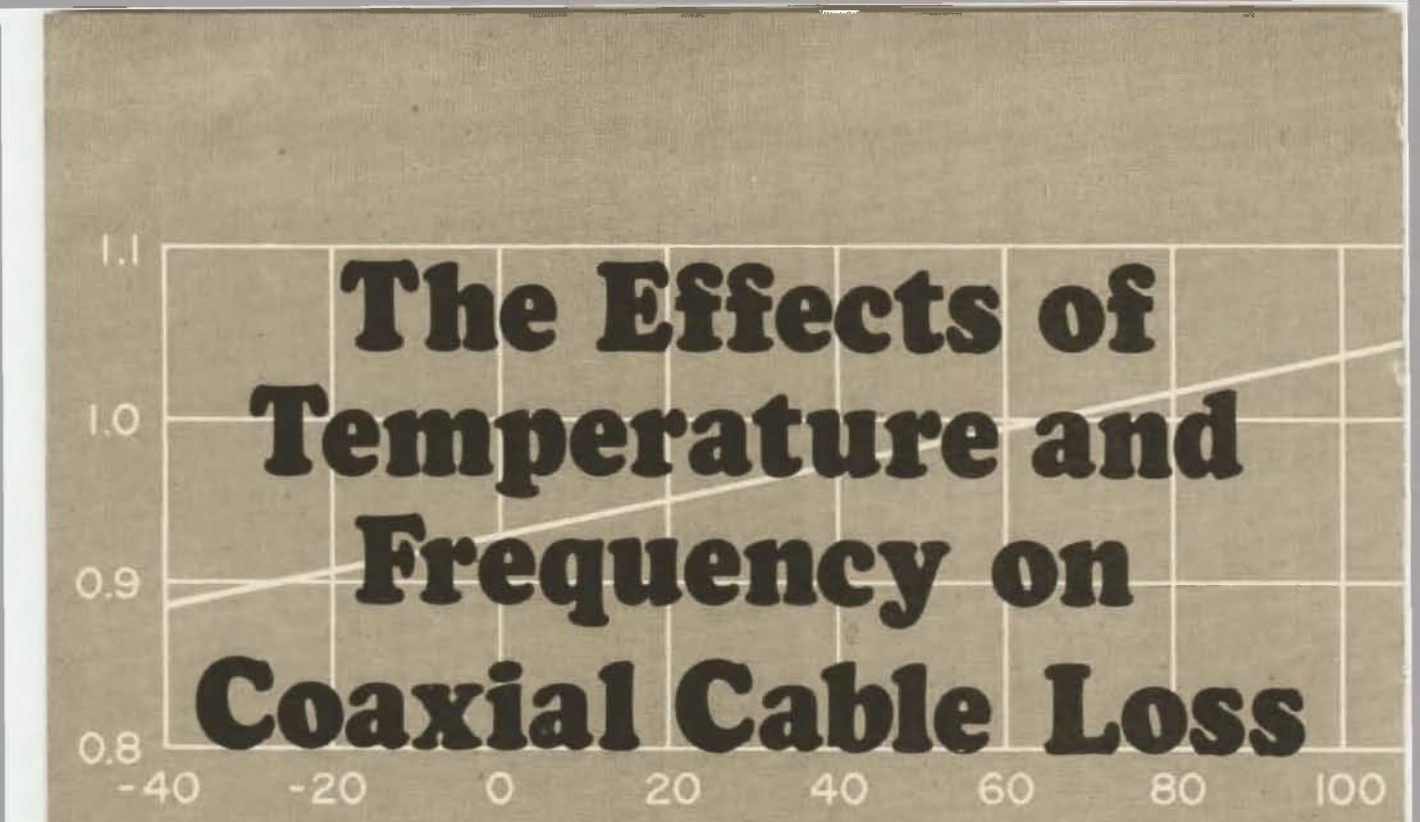
two receivers from one ANTENNA

The classic method of using two receivers on the same antenna is to tie them in parallel directly or use decoupling resistors. But for my money, both methods result in unacceptable compromises in performance. Being a purist, and more importantly, a DXer, a 1 or 2 dB drop in signal can mean the difference between hearing a rare one or not.

As an alternative, I purchased (from Permag Pacific Corp., 5441 West 104th St., Los Angeles, California 90045) a ferrite core, Indiana General CF 108-Q2 ($1.25). This core is good to 50 MHz.

Three trifilar windings of 26 AWG wire were wound on the core, care being taken to space the turns around the core. I then used coil dope to hold them in place. The primary (antenna input) is 10 turns and the two secondaries (for the receivers) are 7 turns each. All three are used for 50Ω antenna and receiver input impedances.

In my case I use two Collins receivers, a



75S3B and a 75S3. No "suckout" or loss is noted on either receiver, regardless of what band either receiver may be tuned to. In fact, no difference in S-meter reading or audio level can be detected from the antenna straight into the receiver or through the toroid.

One caution: If two different makes of receivers are tied together, some loss may be noted. This occurs because of the differences between the two input circuits of the receivers, and it can be corrected by varying the turns ratio of the two secondaries.

In my case, the toroid was mounted in a small Minibox with three RCA jacks on it. It could just as easily mount in the transmitter or one of the receivers. If used with a transceiver and a separate receiver, the toroid must be put in the tranceiver receiver side at the input of the receiver. It cannot handle transmitter directly!

. . . WA6UFW ■

The Effects of Temperature and Frequency on Coaxial Cable Loss

As transmission line temperature increases, so also does loss — and vice versa. Complicating matters, the losses get worse as the operating frequency is raised . . .

Elliott S. Kanter W9KXJ
3242 W. Hollywood
Chicago IL 60645

Perhaps the most common concern of the amateur radio operator is to get the most signal to his antenna with the least possible loss. This has been true since the first spark-gap was heard, and is equally valid today. This fact of maximum power and minimum loss is a prime consideration in both UHF and VHF communications.

There are many factors which will determine the loss or attenuation we might experience in a coaxial cable run. Some are constants but two specific factors are variable and frequently overlooked. These factors are temperature and frequency. Most of us have seen cable charts where the

loss or attenuation in dB/ft is given, but the figures do not reflect the two very important parameters of frequency and temperature.

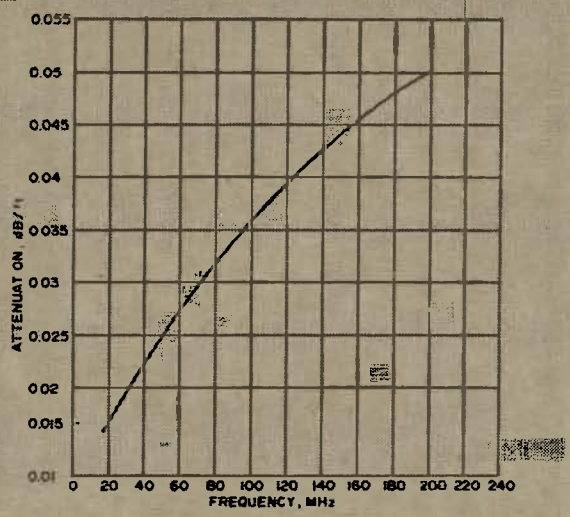


Fig. 1. Signal loss of RG-59/U cable at a temperature of 68°F. Note that loss increases with frequency. The effects of temperature are shown in Fig. 2.

For the purpose of explaining these two parameters more completely, Figs. 1 and 2 were prepared. Figure 1 is a graph showing the attenuation in dB/ft of RG-59/U coaxial cable. If you note the lower scale of this graph, you will find that this graph shows the effects of frequency change on the attenuation. For example, at 20 MHz we can expect a 1.5 dB loss per hundred feet of cable; at 50 MHz a 2.5 dB loss per hundred feet; and at 200 MHz, we note a loss of 5.0 dB/100 ft.

These facts are interesting, but the most important factor is usually ignored. This graph was prepared to show the attenuation of RG-59/U cable at 68°F. Few of us are blessed by living in an area where the temperature is a constant 68° year-round. The midwesterner could expect temperatures of from -40° to +100° in a given year's time. Hams living in the southern states can experience changes of from 40° to 100° in a *single* day. Our graph at 68° is useful, because some basis for measurement must be made, but this does not reflect the various extremes the coaxial cable will be subjected to.

If you dispute the effects of temperature on attenuation, remember the last hot afternoon you operated. Your receiver just wasn't as hot as it was later that night – a

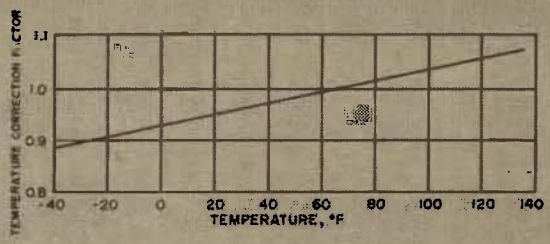

Fig. 2. As the chart shows, coaxial cable exhibits less loss at lower temperatures. To calculate attenuation, the correction factor, determined by ambient temperature, must be multiplied by characteristic loss of cable (Fig. 1).

lot of those weaker stations were lost in the noise. During that day your antenna cable probably underwent temperature extremes from 50° to possibly as high as 120° at mid-day and then back down again.

Figure 2 is a temperature correction graph which will permit you to arrive at the necessary factor by which you can calculate the accurate attenuation loss in dB/ft at any temperature. For example, by consulting Fig. 1 you see that at 20 MHz a 0.015 dB/ft loss exists at 68°F. However, you want to know what attenuation you can expect when the sun is up and the temperature is 100°. By referring to Fig. 2, note that the correction factor at 100° is approximately 1.03. The formula thus tells you that attenuation at 100° is equal to:

1.5 dB x 1.03 = 1.545 dB/100 ft

Similar calculations can be made to arrive at attenuation for lower temperatures as well. Although Fig. 1 was prepared for RG-59/U cable, the correction factor derived from Fig. 2 will apply to any type of coaxial cable you might choose. To make the best use of Fig. 2, you must know what temperature and at what frequency the information in your cable chart was made from. A letter to the manufacturer will usually get this information so that you may make the necessary calculations.

IMPROVING THE PERFORMANCE OF TRAP-TYPE VERTICAL ANTENNAS

The addition of another element can considerably improve the performance of multiband vertical antennas such as the Hy-Gain 12AVQ or 14AVQ models. The added element can be automatically bandswitched and a transmission line system used which allows simple changeover from an omnidirectional to a directive radiation pattern.

Multiband trap-type verticals such as the Hy-Gain 12AVQ or 14AVQ (or homebrew types) provide many amateurs with a multiband antenna system in a limited space. Provided that a good ground system is used, such antennas can prove to be very effective for DX work. The disadvantage to such antennas is that their radiation pattern in the horizontal plane is omnidirectional. If one is interested in DX in any specific area, it is discouraging to realize that only a fraction of the total radiated power available radiates in any specific direction. One solution to this problem is to use another element with the basic antenna. Such an element should be economical, provide an effective directional radiation pattern, automatically bandswitchable on desired bands, and not require any major change to the transmission line system used with a multiband vertical antenna.

This article describes such an add-on antenna element which will provide automatic bandswitching from 20 to 10 meters, develop a directive pattern with at least 3 dB gain, and not require any change to the transmission line system to the trap antenna. Basically, it is a stub bandswitched element properly spaced from the main antenna and fed in such a manner that the current distribution between the main and secondary antenna is such as to effect a directional pattern on the desired bands. Since the scheme used employs direct feed of the secondary antenna or element, rather than a parasitic-type excited element, it is really applicable to a wide range of multiband antennas including horizontal multiband trap dipoles. Of course, when considering a horizontally oriented antenna, the secondary or add-on element would also have to be horizontally oriented.

Basic Scheme

Figure 1 shows the basic antenna arrangement. Either antenna 1 or 2 can be considered to be the trap antenna and the

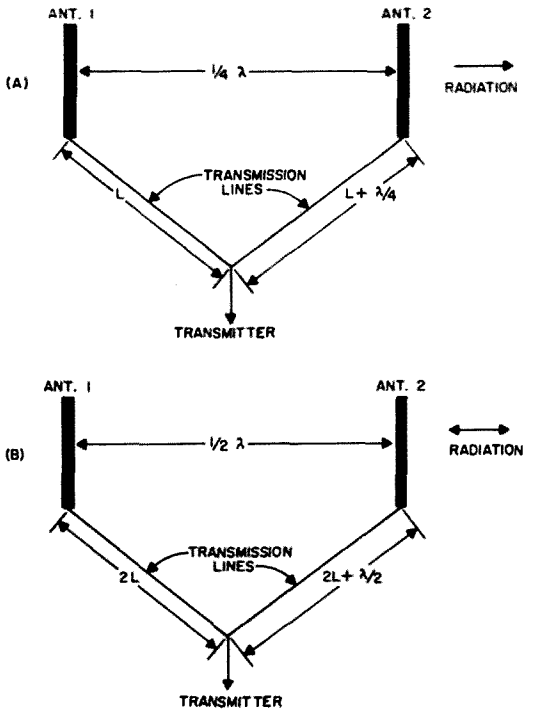

Fig. 1. Two-element antenna spaced ¼λ and fed 90° out of phase (A) automatically becomes ½λ spaced 180° out-of-phase array (B) on second harmonic frequency without changing feedline lengths.

other antenna the secondary antenna. Figure 1(A) shows the antennas separated by ¼λ. The transmission line to the secondary antenna is chosen so that it is ¼λ longer or shorter than that going to the main trap antenna, depending on the direction in which the main radiation is desired. Fed in this manner (90° or ¼λ out of phase) and spaced ¼λ, a cardioid directivity pattern results in the horizontal plane with the direction of radiation as indicated in Figure 1(A). Assuming that each antenna still properly matches its transmission line on the 2nd harmonic frequency, Figure 1(B) shows the spacing and phasing relationships. The antennas are now electrically spaced by ½λ and the one transmission line is ½λ (180°) longer than the other. Under these conditions, the antennas will develop a bidirectional radiation pattern in the horizontal plane as shown by the arrows in Figure 1(B).

The transmission lines are simply paralleled together at the transmitter. This results in a resultant impedance of about 25–26 ohms which the transmitter has to load into, but such an impedance is well within the loading range of almost any transmitter with a *pi* network and variable

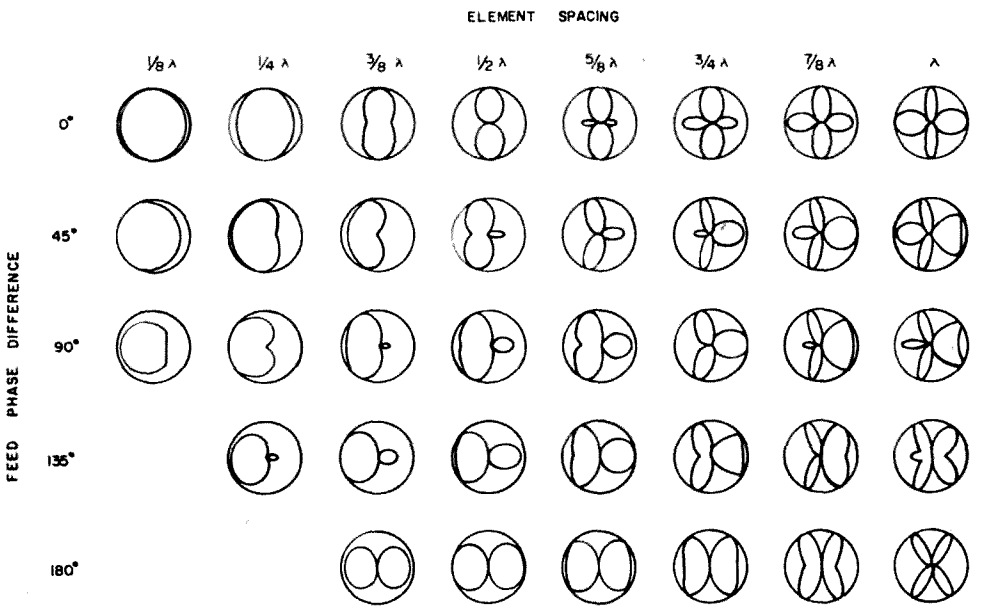

Fig. 2. Besides the usual in-phase (0°) or out-of-phase (180°) current feed systems that appear in antenna designs, a very wide selection of radiation patterns can be obtained by different phasings of two antennas. The patetrns shown are the horizontal radiation patterns. In all cases, the amplitude of the currents to both antennas is equal.

output loading. This is especially true on the higher frequency bands. In order to revert back to omnidirectional operation, the secondary antenna is disconnected at the transmitter and the transmitter reloaded.

The spacings and phasings shown in Figure 1 are conventional ones well known by any amateur acquainted with driven, phased antenna arrays. Many amateurs, however, falsely think that there are only a small number of spacing and phasing combinations that provide useful directional patterns for a driven array with two antenna elements (e.g., ¼λ or ½λ spacing, in-phase (0°) or out-of-phase (180°) feed, etc.). Actually, there are a great many more combinations that can be used, as illustrated in Fig. 2.

From all the combinations shown, it should certainly be possible to develop a useful directive pattern no matter how restricted one may be in the physical placement of the antennas. If the spacing and feedline lengths are chosen correctly, as illustrated in one case by Fig. 1, an effective directional pattern will be obtained without changing transmission line lengths or one or more bands harmonically related to the band for which the antenna array is designed. If there is any difficulty in interpreting Fig. 2, one should first locate the combinations illustrated by Figs. 1(A) and 1(B).

Practical Construction

Figure 3 shows how a secondary antenna was installed with a basic multiband trap vertical in order to provide a directive pattern on both 10 and 20 meters. The spacing and phasing used are those shown in portion of the antenna and the lower approximate 8 ft section acts as a ¼λ vertical on 10 meters. The antenna used was constructed from telescoping aluminum tubing with 1¼ in. o.d. tubing used for the base section. Any similar method of construction can be used but some provision should be made to allow adjustment of the length of the antenna and the stub. The secondary antenna should first be used alone and the transmission line to it checked for low swr (of at least 1.5:1 or less on both bands).

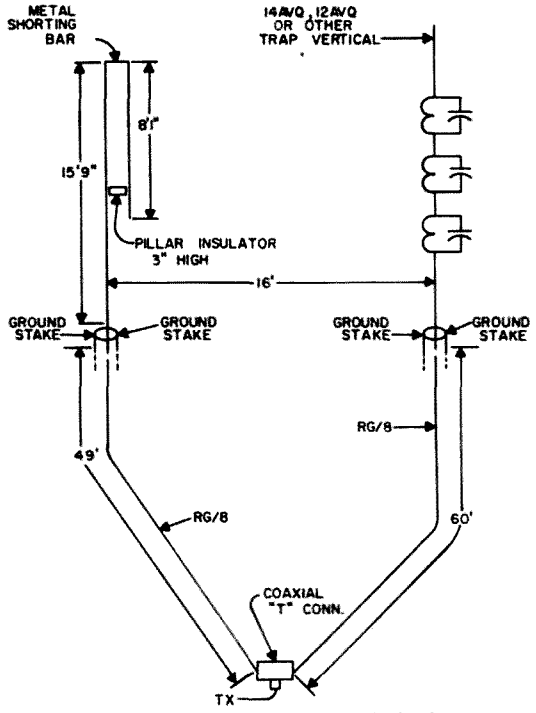

Fig. 3. Secondary stub-bandswitched antenna used with 14AVQ antenna on 10 and 20 meters to form directive array. Feedline system is based on Fig. 1.

The transmission line to the secondary antenna is cut to be ¼λ shorter on 20 meters than the line going to the trap antenna. Note that the velocity factor for coaxial transmission line (.66) must be used when calculating the ¼λ difference in length. The two coaxial lines are joined together via a coaxial tee connector which mounts directly on the coax output jack on the transmitter. For omnidirectional coverage or for operation on a band where the secondary antenna does not resonate, the coaxial plug for the secondary antenna is simply unscrewed from one side of the tee.

Summary

The use of a simple secondary antenna can increase the gain in almost any desired direction by usually 3 dB or more when used with a trap vertical. There is no need to limit oneself to conventional antenna element spacings or phasings. One should carefully study Fig. 2 to decide which spacing and phasing suits a given situation. Then, one can proceed with usage of the secondary antenna in the manner shown for the specific construction example shown in this article. . . . W2EEY/1 ■

Measuring the Difference Between INCIDENT & REFLECTED RF

Bob Eldridge VE7BS
805 East 20th Avenue
Vancouver 10, BC

When there is some standing wave on a feeder, the actual reading on your directional coupler doesn't really mean very much unless you keep adjusting the "forward power" for full-scale deflection before reading the scale on vswr.

Generally speaking, you won't go far wrong if you concentrate on tuning your antenna or transmatch for minimum reflected power, but sometimes you may find the "forward power" has suffered by more than the amount by which the reflected power has improved.

On some meters you can watch the forward and reflected scales simultaneously; this is fine if you have the knack of reading two things at once and separating the two facts in your brain, or in effect reading the *difference* between the two readings.

This is the kernel of the whole affair. The only thing that really matters is the difference. True forward power, that is the power transferred to the load, is the difference between *incident power* (power registered on the meter as going forward) and *reflected power* (that registered as coming back). Don't forget that you are really reading *voltage* across the line, so halving the reading represents a 6 dB reduction.

If you want to be fussy, you don't really transfer that much, because some of the incident power is lost on the way up the feeder, and some of the reflected power is lost on the way down. This makes the picture look brighter than it really is.

At HF there isn't much loss in feeders, but at VHF and UHF it is quite a different story. If you have 6 dB loss in the feeder your vswr meter will read a reasonable vswr even if the antenna is quite seriously mismatched at the top of the cable. For example, an antenna with a radiation resistance of 250Ω (vswr of 5 to a 50Ω coax cable) will cause an apparent vswr at the transmitter of only 1.4:1.

Here is a graph which relates apparent to true vswr for various feeder losses. I hope it doesn't depress you.

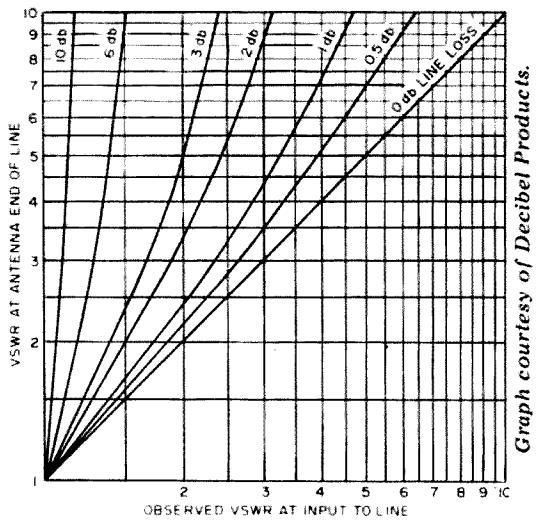

Fig. 1. Curves showing actual versus observed vswr for various line losses.

Tuning Indicator

There is a useful trick in wiring directional couplers (Mickeymatches, Monimatches, Micromatches are all directional couplers):

Close S1 and read incident power.

Close S2 and read reflected power.

Close both and read the *difference*, which is all you need most of the time.

Close them both and the TVI disappears.

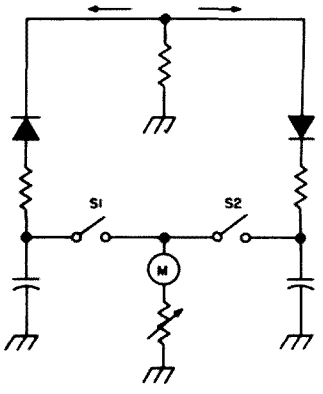

Fig. 2. Reversed diodes can be switched in the circuit to indicate incident, reflected, or "difference."

Note that the diodes are in opposite polarity. Each presents the opposite sign of dc voltage to the meter, and the meter reads the amount by which one exceeds the other. Incident power always wins out over reflected power; it had better, because there is something screwy if more comes back than originally got to the load!

The better the match the greater will be the true forward power into the transmatch.

If you have a short length of coax between the transmitter and the transmatch, and no 50Ω "black boxes" in the line (lowpass filters and the like), it doesn't do much harm if the transmatch cannot transform the feeder impedance down to 50Ω. If the best you can do is tune the transmatch to look like 100Ω, that is fine as long as the transmitter is adjusted to load into 100Ω. Be careful, though, if there are filters in the line, or you may hear your modulation talking out of the black box, and that spells trouble!

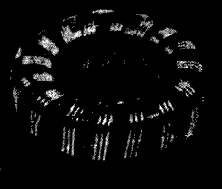
GUARANTEED CUBICAL QUADS

PRE-TUNED — COMPLETE
PRE-CUT — PRE-DRILLED



QUADS ARE BETTER BECAUSE: They have more gain than flat tops, element for element—Are quieter—less static and ingnition noise—Possess lower vertical radiation angle—Require less space—(½ width of flat tops)—Greater capture area, so better on weak signals—Negligible corona losses—Excellent SWR/Freq. characteristic—Light weight (30 lbs for 2 el, 60 lbs for 4 el) Detuning less from nearby objects. Your choice, bamboo or fiberglass—no aluminum spreaders. Bamboo exceptional quality and half the cost of fiberglass. SPECIAL DEAL on purchase of an E Z WAY Tower/quad combination. Free literature.

CB Quads from $59.95

For many years Uncle Sam's surplus electronics have been a gift horse to many hams and electronic experimenters alike. However, in the last few years, good surplus has become increasingly more difficult to locate. Yet, there is one open door to the bargain store. Buy government surplus straight from the horse's mouth!

There isn't anything difficult or mysterious about buying direct from the government. It's simply a matter of knowing who to contact and what procedures to follow in order to buy. Although the government sells as surplus almost any item imaginable, our discussion will be limited to the sale of electronic equipment. All government surplus is sold through two agencies. The Department of Defense sells property belonging to the armed forces and therefore has the most property for sale. Property from all other departments and agencies is sold through the General Services Administration. In the last couple of years, very little electronic equipment has been offered for sale by the GSA. Most of what has been available was airport navigation equipment, although some communications items and some test sets were sold.

Government sales are of the auction, spot bid, or sealed bid variety The latter is the only one that will be discussed here. A sealed bid sale will begin with the receipt of a catalog listing the items for sale. Each item will be described as completely as possible by the office issuing the catalog. But sometimes this is nothing more than the equipment "type designator" number or a federal stock number. Each listing will also contain the quantity offered for sale, whether it is new or used, its condition,

Letter	First Digit	Second Digit	Third Digit
A	Airborne (installed & operated in aircraft).	Invisible light, heat radiation.	Auxiliary assemblies (not complete operating sets).
B	Underwater mobile, submarine.	Pigeon.	Bombing.
C	Air transportable (inactivated).	Carrier.	Communications (receiving and transmitting).
D	Pilotless carrier.	Radiac.	Direction finder and/or reconnaissance.
E		Nupac (nuclear protection & control).	Ejection and/or release.
F	Fixed.	Photographic.	
G	Ground, general ground use.	Telegraph or teletype.	Fire control or searchlight directing.
H			Recording and/or reproducing (graphic, meteorological, and sound).
I		Interphone and public address.	
J		Electro-mechanical (not otherwise covered).	
K	Amphibious.	Telemetering.	
L		Countermeasures.	Searchlight control (inactivated; use G).
M	Ground, mobile (installed as operating unit in a vehicle which has no function other than transporting the equipment).	Meteorological.	Maintenance and test assemblies (including tools).
N		Sound in air.	Navigational aids (including altimeters, beacons, compasses, racons, depth sounding, approach and landing).
P	Pack or portable (animal or man).	Radar.	Reproducing (inactivated).
Q		Sonar & underwater sound.	Special, or combination of purposes.
R		Radio.	Receiving, passive detecting.
S	Water surface craft.	Special types, magnetic, etc., or combinations of types.	Detecting and/or range and bearing.
T	Ground, transportable.	Telephone (wire).	Transmitting.
U	General utility (includes 2 or more general installation classes, airborne, shipboard, and ground).		
V	Ground, vehicular (installed in vehicle designed for functions other than carrying electronic equipment, etc., such as tanks).	Visual and visible light.	
W	Water surface & underwater.	Armament (peculiar to armament, not otherwise covered).	Control.
X		Facsimile or television.	Identification and recognition.

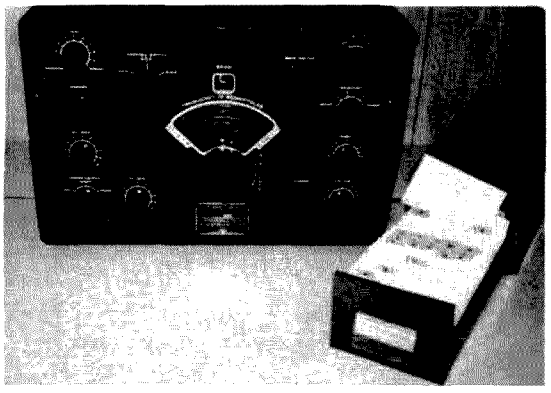
Table I. Equipment Indicator Letters, "AN" Nomenclature System.

(good, fair, poor, or scrap) whether it is packed or unpacked, the total acquisition cost, estimated total weight, and the location of the property.

After you've found an item that looks interesting, it's time to determine the amount of your bid and make an offer to buy it. Several important things figure into this process. First, all items offered for sale are "where is – as is." This means the government does not guarantee that the description covering the item under consideration is 100% correct. (The descriptions I've seen have *usually* been accurate, but they are not guaranteed.) With this in mind, I strongly recommend that you take advantage of the inspection period that precedes each sale. During this inspection period, all items are on display for prospective bidders to make their own determination of type and condition. Dates and times of the inspection period for a particular sale are found in each individual sale catalog.

Most bidders are unable to view the offerings first hand due to the travel requirements and must use the written description and their knowledge of military electronic nomenclature to determine the amount of their bid. I use a list of AN nomenclature (Table I) plus a card file as an aid to bid determination. Another important consideration is the location of the property. The bidder that is awarded the sale is responsible for removal of the property within a specified time, usually

30 days. Unless you can pick up the property yourself, the expense of having a commercial firm pack and ship it will be incurred. This cost should be taken into consideration when determining the amount of your bid. A list of packers and shippers serving the activity where the property is located is available from the office issuing the sale catalog. An item containing but one kind of property is offered for sale on a unit basis with the bidder being required to buy the total quantity listed. An item containing two or more kinds of property will be offered for sale as a *lot*. Property in a lot cannot be separated for bidding purposes. Everything listed must be considered as one unit. In bidding on a lot, a unit price bid is not required. Only total price.



After considering what it is, where it is, and how many there are, you enter your bid on the form enclosed with the catalog. Instructions for completing and mailing the bid form are contained in the catalog and on the form itself, and will not be covered here. The only point worthy of mention is the bid deposit. A deposit of at least 20% of the total amount bid is required to accompany the bid form. In this respect, I have found postal money orders are superior to personal checks. Awards are processed faster when money orders are used and they don't foul up your checkbook when returned from an unsuccessful bid. They are good for five years and can be used as deposits over and over again.

After submitting a bid, three things can happen. You can be outbid, in which case your deposit will be returned. You can be the high bidder and receive the award for the sale. In this case, you pay the balance of the amount you bid and start making arrangements for removal of the property. Or you might be the high bidder and have the government reject your bid as giving them insufficient return. You get the deposit back, but it's very disappointing to be the high bidder and lose. All the bidders participating in a sale receive an award sheet which lists all successful bidders and the amount paid for each item. The sheet also shows which items didn't receive any bids at all and which items were witheld for insufficient return.

Government property is being offered for sale in locations all over the country. The General Services Administration sells through 10 regional offices scattered throughout the country. Each of these offices maintains a mailing list for persons interested in bidding on property located within the region controlled by that office. For a list of regional offices and their addresses, see Table II. Write any office, requesting that you be put on the bidders mailing list. This request will bring a form on which you select the type of property you wish to bid on. Mailing this form back

Geographical Area	Address

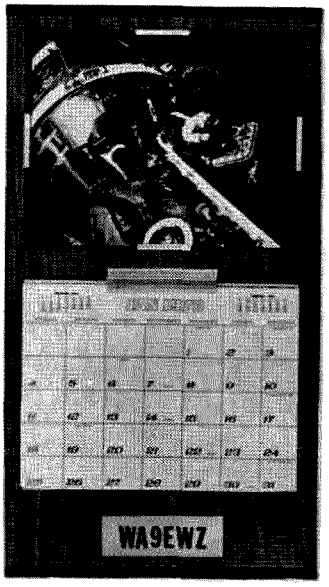
Table II. General Services Administration Regional Offices.



A bargain receiver purchased from the government and the card file the author used to identify it.

to the regional office places you on their bidders list. To be placed on the list for Department of Defense sales, write the Defense Logistics Services Center, Federal Center Building, Battle Creek, Michigan, 49016. This request brings a booklet listing the classes of property sold by the department and a bidder's application form. Fill out the form indicating the classes of property you wish to bid on and the geographical areas in which you wish to bid. When this form is returned to the logistics center, they will place you on the bidders list for the property and areas you have specified. They will also issue you an identification card containing a bidder identification number. Save this card. Your bidder identification number must be placed on all bids you submit.

That covers the highlights on how to bid and how to get placed on the lists. Now you're ready to try your luck. At the start of the article I said that this is one avenue to a bargain. That it is. But not all the time. It's hard to get a bargain when packing and shipping charges are added to the sale price. The closer you are to the location of the property, the better your chances. Another asset is a good knowledge of military equipment nomenclature. If you can identify a good piece of equipment from no description other than the AN nomenclature or type number, your chances of getting a bargain are materially increased. Don't be too upset about repeatedly being outbid. The ones you win will be worth waiting for.

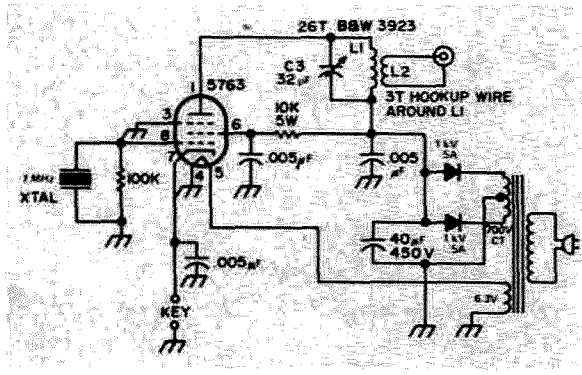
QRP

Whether you like low power or superlow power, you'll appreciate the simplicity of these two rigs for CW operation on 40 meters.



Ever want to try a hand at QRP operation? Here are two rigs that run low power on 40 meters at low cost.

The first rig (Fig. 1) uses a highly efficient 5763 tube and runs about 13W with a 350V supply. The B+ voltage may be dropped down for lower power operation. Almost any power supply delivering about 350V for B+ and 6.3 for the filaments can be used in place of the one shown. Adjust C3 and the position of L2 for maximum output and best keying.

The second rig (Fig. 2) runs about 40 mW with a 9V battery supply. Transistor Q1 can be a GE-1, 2N247, 2SA268, 2N416, or 2N394. Adjust R1, C1, and C2 for maximum output and best keying.

With the 5763 Rig running 13W, I've worked as far as Athens, Georgia (475 mi.) with a 5 x 9 report. Cutting down the power to 5W with a Variac, I worked as far as Syracuse, N.Y. (200 mi.) with similar results. With the transistor rig, I ran some tests with WA3EYL about 2 mi. away. Copy was solid, even when the output power was reduced from 40 mW to only 2 mW.

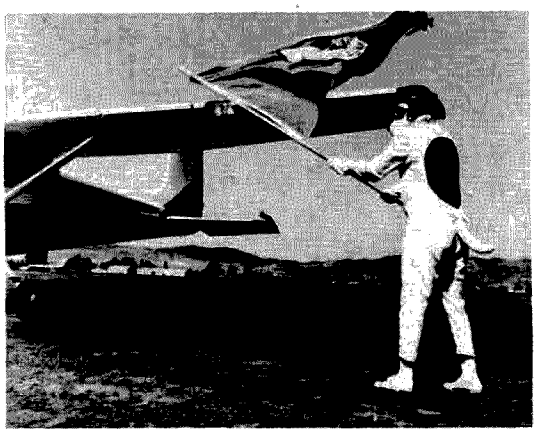
GROUND FOR The Powder Der

A. David Middelton W7ZC
Box 303
Springdale UT 84767

It is the morning of Independence Day, and Lindbergh Field is socked in – closed. Poised on the San Diego runways are 92 planes all with lady pilots ready to take to the air for the 23rd Annual Powder Puff Derby!

The destination is Dulles Airport, Washington, D.C., over a prescribed 2500-mile route with designated checkpoints and stopovers.

Amateur radio's problem: Relay to race officials, on both coasts, arrivals and departures of all 92 planes at every one of the nine checkpoints along the official route from San Diego to Washington.



Here is a true account of four days of genuinely worthwhile *communications* by a handful of dedicated ham operators. They sweated, cursed, (as off-the-air "asides"), and battled propagation that ranged from fantastically good to impos-

sible. And they provided a reliable and almost continuous flow of *intelligence* in a 12-station relay back and forth across the U.S.

Time was when the word "relay" was synonymous with amateur radio. Today, there is little or no relaying being done except on established traffic nets. Another facet of old-time ham radio has all but vanished: the requirement for total *accuracy* in the passing of information from one station to another. All thinking people know what happens to word-of-mouth messages: they usually come out well garbled.

The Powder Puff Derby relay network requires total accuracy, without delay, and full cooperation between operators who have no previous experience in working each other. Many are participating for the very first time, though the Derby is an annual event.

Honorary Starter "Snoopy" waves off first of the 92 planes in the '69 Powder Puff Derby, with the flag bearing official San Diego bicentennial emblem. (Who's Snoopy? – Ruth Ebey of San Diego.)

By the time the fog lifted at San Diego and the planes were cleared for takeoff, three of the entries had been scratched. But the 92 did get under way, and the radio operation swung into action.

At first, things were confused and hectic, as is often the case with such ambitious undertakings. An FAA official called, via ham radio, to ask how many planes had bypassed St. George. Such a question might be perfectly normal, but it had been asked before the race had even started. Once the gals were airborne, though, radio traffic began to fall into something of a routine.

Nervousness settled over race officials as well as members of the communications net when, 12 hours after the planes had departed, one of the contestants was unaccounted for. A concentration of cooperative effort within the framework of the nationwide network managed to turn up the elusive missing plane, and the net secured for the night. The first leg of the race had ended with no casualties and no critical problems. But that was just the first day.

The second day was no more than a few hours old when, from W7LYV, came the report: "Plane down and burning near Jacobs Lake, near the north rim of the Grand Canyon."

Quickly, the net control station passed the word that the downed plane was *not* one of the Powder Puff Derby contestants, although it was in the general path of flight. The ham who originated the call, W7LYV, alerted the Federal Aviation Agency and the Arizona highway patrol, but the net control station kept the message from being relayed east of Salt Lake City. No need to pass traffic that was not pertinent to the race, the reasoning was; and besides, like any message, news of an accident, even though unrelated to the Derby, could be misunderstood or misinterpreted at subsequent checkpoints, resulting in needless confusion and concern.

When the emergency traffic had cleared, the network bustled with routine messages going both ways along the route; thousands of bits of information were passed from one point to another. The planes began together, but now they were strewn in the air over the entire flight route; and the communications had to cover the complete range – from the area of the first femme pilot to that of the last. The network was alive with traffic all right; but it was organized, tersely worded, efficiently passed.

All afternoon and evening of July 6, radio and TV weather reports indicated rapidly deteriorating flying conditions in the midwest, with a bad front moving into the central and eastern portion of the U.S. The racing ladies were heading directly into very bad weather! Many set down and stayed put in various locations to avoid flying into the storm!

As the net ended its second day, all planes but one were once more accounted for. The FAA was alerted, and an official follow-up would provide data on that last elusive straggler.

The results of the first two full days of the Derby Relay Net indicated a splendid spirit of cooperation, a high order of discipline, and an intense interest on the part of not only the relay members but by nonparticipating amateurs as well, many of whom called in to briefly express an interest in the race and in the net. W6OII at Carmel, Calif. performed yeoman service policing the 40 meter frequency of oper-

ation during these first two long days of this hectic communication problem.

Problems

The weather was bad in the midwest and east as the third day began. Severe storms raged over all the route east of St. Joseph, Mo. At 1920 GMT, WØQOQ reported from Kearny that all planes were still on the ground. Not one of those sensible gals chanced a takeoff in the face of that storm!

Then that seemingly inevitable result of all huge nets happened. The messages became increasingly contradictory. Here is the log for the afternoon of the third day.

1423Z – WØNH reports via relay that 13 planes have departed but 9 still left at St. Joseph.

1432Z – W9JLL tells W8VA that planes 24, 14, and 21 departed Mt. Vernon. The ladies are moving east again!

1438Z – K7FCN says his two birds still on ground at SLC. No one knows why the delay.

1445Z – K7FCN breaks in to say that one plane is in the air and one on takeoff strip. This clears SLC of all his planes.

1447Z – Plane 21 had been scratched prior to the start of the race; yet it kept showing up in checklists. A critical look is taken at information sources and word goes out to correct and prevent such errors.

1529Z – WØQOQ says that NO planes have departed Kearny.

1543Z – WØQOQ reports that No. 8 departed Kearny on a "special V F R" after much deliberation between Kearny and San Diego regarding race rules.

1546Z – W7ZC reads W8VA, Huntington, directly (W8DUV, YL Kay, operating).

1640Z – WA7DUG, Fran, Las Vegas, checks into net. (She was to be active and a great help in checking racers' locations during the remainder of the race.)

1701Z – Plane 40 arrives at Dulles Field, the terminal point.

Marilyn Copeland and Pat McEwen, both of Wichita, Kan., ready to board Pat's snazzy checkered racing Beechcraft Bonanza V-35A.

1720Z to 1817Z – Scores of arrival and departure times relayed by stations east and west of Kearny as the racers move eastward.

1817Z – The RONS (required overnight stays) for the third night begin. And planes are scattered!

1956Z – WØQOQ sends W9JLL a request to determine accurate list of *arrivals* at Dulles, but no information was received in reply to this formal request.

The conflicting reports and incompleted message loops raised questions among the responsibles of the communications networks. And at 2013 GMT (or Z), W6KBT, the western net control station, suggested that all stations furnish "modus operandi" of relay station setups along with lists of participating personnel. It stood to reason that if the net operation was to be smoothed in future efforts, the place to begin was in the organization. Mailed questionnaires would be put into circulation after the Derby.

Meanwhile the gaps in the relay net were widening and difficulty was mounting in handling data from the midwest across to the west coast. And still no word on arrivals. At 2050, a message from W6KBT to destination stations K4EAM, W8VA, and W9JLL: "Imperative expedite arrival times your station". Still no reply. The net control kept pressing W7ZC to obtain

"Granny" Maybelle Fletcher, pilot, and Jackie Kelly (copilot not shown) made a fetching pair in their red dotted tops and tattered minis.

information from the east regarding arrivals. For some reason, information seemed to be flowing to the east but little data flowed from the east to the west.

Eventually, the long list of arrivals at Dulles was received in the west directly from WØQOQ by W7ZC. The Kearny station was the sole remaining link between east and west. Relay possibilities east of Kearny were scant; clearly, a communications breakdown had developed along the last leg of the route.

The snafu continued the following day. Western station W7ZC made repeated all-out attempts to establish contact directly with *any* Washington, D.C. station, irrespective of its net participation. Dozens of calls made on all modes and frequencies yielded no response from the Washington area!

Finally, at 1830, W7ZC raised W3NY, near Washington, and explained the situation. W3NY, unable to raise K4EAM, managed to make contact with a Huntington station. Thus, the net stepped out of the net to maintain a flow of communications. Through a series of schedules, W3NY passed additional data updating the location of racers.

There was no explanation of the failure of all other Washington area stations to reply to W7ZC's repeated directional calls, particularly in view of the fact that W3NY reported the western station's signal was consistently loud and clear.

Even though not a smashing success, the Derby relay net worked! The team had successfully moved traffic efficiently and accurately across the U.S.

There were a few unsatisfactory conclusions. Information is still unavailable as to why Dulles did not originate and forward more data to the western race officials, via the relay. Information from Dulles was frustratingly sparse, and especially on the last day.

In spite of the communications blackout in the east (or boycott), the event spoke well for the amateur fraternity. Had it not been for the fine cooperation of non-net W3NY, and the continued activity at W8VA, W6KBT (who was being queried by race officials) would have been left without any news.

Word reached W6KBT after the relay that K4EAM operated under a severe handicap due to station location and a poor antenna. And, of course, the complete lack of any transcontinental circuit severely hampered net operation.

On July 3, 1970, the 24th annual Powder Puff Derby will begin from Monterey Peninsula Airport in Northern California. As the damsels make their 2760-mile trip to Bristol, Pennsylvania, the ground-based observers will again be looking to the amateurs for their communications support. Will they get it?

Possibly! Here's some insurance measures:

1. Establish a *trunk* system, with relay terminal stations *not* located *at* the Race airports, but with these stations serviced by "drops" from the airport. These "drop" circuits should be on a different frequency from the net itself, preferably on VHF FM. This method was very successfully used at several stations along the relay.

Placing stations *away* from airports would permit *better* installations and antennas due to restrictions enforced by airport communications managers.

2. Establish adequately equipped and manned stations (with CW and SSB facilities) plus suitable antennas and operations space, for totally reliable communication along the net system. Redundant or at least multiband equipment is desirable. Each relay station must have *total* communication with the stations in both directions.

Though it is not necessary for a relay point to be able to communicate with stations beyond the next one, it is highly desirable – as proved in 1969 when communications was maintained across wide gaps because of poor conditions or other reasons.

Emergency power may well be a requisite, especially at key points! Mobile units might provide such links if the system chain is broken.

All stations should be capable of operating at their maximum potential, as this is badly needed when QRM, QRN, or propagation causes difficulty.

Station planning must be done *in advance.* Jury-rigged antennas and facilities prove a handicap to the system.

3. Alternate frequencies should be predetermined, preferably in the lower ends of the bands (less QRM) by providing upgraded licensees and equipment. At many points difficulty was had in finding *any* reliable operators. A few upgraded licensees *did* take time and have sufficient interest to be valuable to the net's operation.

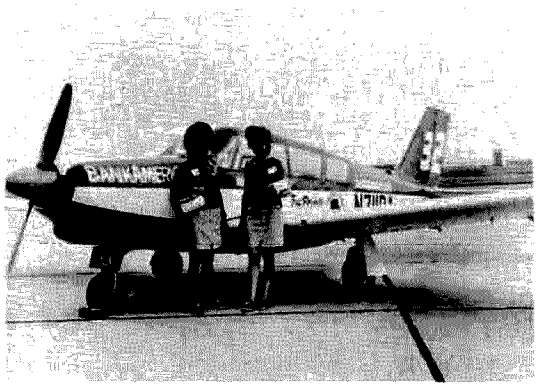
4. Establish better liaison between race officials (having data) and operators at relay points. This is a matter for race officials working with net personnel.

At each western station, operators were ready, able, and willing to do their job without delay. In some locations it appeared that race officials were indifferent or were uninformed as to the net's purpose and availability, resulting in a delay in passing information.

It is clear that the prime consideration is the safety of the pilots and crews – that the transmission and reception of arrivals and departures is secondary. However, this "flying safety" may require accurate updated information in the event of a mishap.

The amateur operators were aware of this and did expeditiously handle all information given them. But it was not charged to the net.

The Powder Puff Derby relay net is a *service* operation and all who participate should take cognizance of this fact. Net responsibilities include the establishment of suitable equipment and operational facilities to maintain solid communication back and forth across the country in order to handle data supplied by race officials.



It follows, therefore, that race officials should extend the same full spirit of cooperation to the amateur radio operators so that the fullest utilization may be made of far-flung net talent.

Now. What about that Powder Puff Derby coming up? Where and how do the misses and Mrs. fly?

On July 3, the 24th annual Derby will take off from Monterey Peninsula Airport in Monterey, Calif.

Safe and sound all the way from San Diego to Washington, D.C. Crew #55 from San Jose, Calif. are greeted by pilot/author and president of National Aviation Trades Association, Frank Kingston Smith. (At controls) Layne Hackett, "Cumulus" held by Betty Hicks, world famous golfer. (No dog-sitter could be found so Cumulus had to race, and loved it.)

It's Fess Parker's Piper Comanche PA-24; this team flew in the coast-to-coast dash, "Daniel Boone" himself capped the pilots of #32 just before takeoff. L. (Copilot) Billie Herrin.; R. (Pilot) Margaret Mead, winner of the Derby in 1968.

"Snoopy" on Louise White's Mooney Super 21 might have had a rough ride, but pilot Louise looks cool and relaxed after arrival at Dulles, although thunderstorms plagued the last half of the race route.

K7UGA Harmonic. – *All hail the happy winner of the 1969 Powder Puff Derby, as Congressman Barry Goldwater, Jr. hands her the trophy at the awards banquet held at Marriott Twin Bridges Hotel, Virginia.*

The race is open to all qualified women pilots flying stock model, fixed-wing, single or multiengine aircraft. As always, only daylight flying in VFR (contact) weather, as defined by the Federal Aviation Administration, is permitted. Winners are determined on a handicap basis, "par speeds" having been established based on figures available from manufacturers' data for each make and model of aircraft. Since takeoffs are in order of entry, winners cannot be known until all planes have crossed the finish line.

Climbout will soon take them over the fruited farms of Fresno, first of the 10 *en route* stops officially designated for refueling and remaining overnight. Stop towers will be equipped with Simplex time stamps so that after the flyby of the timing lines, time will not be counted in the final scoring until the wheels start their takeoff roll on the runway.

Racers will point their noses into the blue to clear Mt. Whitney's 14,000 foot peak. They will overfly the blinding gleam of Death Valley before letting down into star-studded Las Vegas. Eastward, they'll flash over the desolate beauty of a last frontier with its intricate spires and serrated ridges, the brilliant red sandstone of the Valley of Fire, and the goosenecks of the river canyons, to arrive at the foot of the penetrating blue, serpentine Lake Powell at Glen Canyon Dam and Page, Arizona.

Continuing along the north rim of the mighty Grand Canyon, contestants will enjoy unlimited visibility encompassing Zion National Park with deep purple gorges, sculptured Bryce Canyon, Rainbow Bridge – "one of the seven natural wonders of the world," Monument Valley with its red cliffs, and volcanic Shiprock before arriving at booming Farmington, New Mexico, "Energy Capital of the World."

From here it's still high country with a let-down over the Navajo Trail for a *must* flyby at Johnson Field in Walsenburg, Colorado, before heading for a *must* stop at Peterson Field, Colorado Springs in the shadow of 14,000 ft Pikes Peak. Desire to linger in the Garden of the Gods, red monoliths scattered among green fields, and at the architecturally beautiful Air Force Academy, must be denied with the longest leg still ahead: 375 miles into Hutchinson, Kansas. From this prosperous

city, contestants may press onward without oxygen if lower winds are favorable, to revisit Springfield, Mo., then into the business hub of northwestern Tennessee, Dyersburg. A high welcome awaits the racers at this mandatory stop.

Then it's a takeoff on a northeast heading for historic Louisville, Ky., which combines midwestern vigor with southern charm.

Off and upward the racers will press to Morgantown's splendid airport set atop one of the verdant hills of West Virginia.

The final lap is a hurdle over the sprawling Allegheny Mountains into the 3 M Airport, Bristol, where the Pennsylvania Turnpike Bridge over the Delaware River connects Lower Bucks County with New Jersey. Here, atop their tower, the timers will click off the final seconds for each plane as its crew flashes past the glorious orange finish line, salute to a challenge accomplished.

Contestants will be vieing for the $5,250 purse to be divided among the top five winners. Trophies will be given, as well as several thousand dollars more in additional prize monies for the best scores between stops, best in each horsepower class of aircraft, and in other specialized categories.

The racers will help Monterey celebrate its bicentennial. Sponsoring the start is the Monterey Bay Chapter of the Ninety-Nines. The terminus is being sponsored by the Eastern Pennsylvania Chapter of the Ninety-Nines.

And for the 18th consecutive year, the radio net will be furnished by ham radio.

Considering the checkpoints between the two terminal points, the total ground distance covered, and the very large number of people participating, it is truly no wonder that two-way coverage gets to be a problem at times. But improved procedures and a determination by conscientious amateurs will combine to make the next Derby the most successful of all.

COAX ADAPTER VHF to BNC

Many new converters, SWR meters, and other accessories are now coming out with the newer BNC coax connectors on them. Most hams have been using coax equipped with the PL-259 plug or similar larger size connector. A simple, easily-constructed adapter can be assembled as follows, at a cost of approximately 75 cents according to current "bargain-counter" prices. All that is needed is one PL-259 plug and one UG-1094/U. The latter is the BNC type also known as UG-625, and is the single-hole chassis-mount version.

Drill and tap the neck of the PL-259 3/16 inch from the end with a 6-32 thread, and fit this threaded hole with a flat-head screw. Solder a piece of 16 or 18 AWG wire to the center pin of the BNC fitting, cutting it long enough to extend through the center pin of the PL-259 when the BNC fitting is inserted into the neck of the PL-259. The BNC fitting has a flat on its threaded surface; tighten the setscrew against this flat, and solder the wire to the center pin of the PL-259.

The photograph shows the "before and after" views of the assembly. This makes a sturdy, short, convenient adapter, and takes ten minutes to assemble, preventing loose, haywire lash-ups.

21 dB of gain on 2 meters with a new approach to the construction of VHF beams

by A.H.C. Smirk, B.E. ZL4TAH
(Reprinted from Break-In)

Introduction

Of all the components making up a VHF installation the antenna offers the most potential for improving a station's capability. For those who may have doubts it is pointed out that with the low-noise transistors available today, such as the MPF107 of the field-effect type, it is relatively easy to obtain a good noise figure; however, the overall noise figure of a VHF receiving installation is affected by the gain of the antenna. The improvement that can be obtained by increased antenna gain depends only upon the size of array that it is practical and economical to construct.

In recent months I have developed a suspension system for VHF antennas where the rigid booms and structural framework of the conventional high-gain antenna are replaced by ropes under tension. With this system it is easy to construct very long yagi antennas which individually have the same gain as stacked arrays of conventional design.

The 32-element yagi described in this article has a length of 73 ft, a theoretical gain of 21 dB, and can be constructed from all new materials for less than $10. Photo 1 shows a completed 32-element beam before it was raised onto its masts. Antennas of this form could properly be described as suspended long yagis and I suggest that they should be called "sly" beams, using initial letters to form the acronym.

Electrically the sly beam is identical to a rigid boom yagi of equivalent length except that the elements are slightly shortened to compensate for the removal of the usual metal boom.

Suspension Cords

Ordinary cotton or hemp rope is not satisfactory for the suspension cords as these materials absorb water into their fibers resulting in swelling and shrinking. Furthermore, the length of such ropes depends upon the period for which they have been subject to load, a phenomenon known as "creep." For any VHF antenna it is a fundamental requirement that elements must have the correct spacing at all times when the antenna is in use. Nylon cords generally do not absorb water into the fiber, but some types will hold water by capillary absorption between the fibers. A 120 lb breaking strain fishing line made of "Ulstron" fiber has been found to have adequate mechanical properties. (It is New Zealand made, so may not be readily available in all areas. But parachute cords, deep-sea-fishing lines, and other high-strength nonporous cords should be equally suitable.)

Elements

With yagi antennas the directors may be all of the same length or of decreasing length with distance from the driven element. In the former case the optimum length for all director elements depends upon their total number. When there are more than 12 in number, the length of directors becomes less than 36 in. for a design frequency of 144.2 MHz. Aluminum welding rod of 1/8 in. diameter is supplied in 36 in. lengths and is a ready source of elements. The low-cost, lightweight and high-conductivity characteristics of aluminum make it an ideal material. For the driven element and reflector which are necessarily greater than 36 in. long at 2 meters, solid brass rod of 1/8 in. diameter has been used. It is available in long lengths from suppliers of nonferrous metals. The lengths and spacings of all elements for the 32-element sly beam are given in Table I.

Matching

Most of the usual forms of impedance matching should be satisfactory with the sly beam. I used a 300Ω delta match at the driven element and a length of 300Ω slotted, balanced TV feeder to a fully adjustable balun at the transceiver. To some, this system may seem a bit crude but it does contribute to the overall simplicity of the antenna. Results using the delta match are very satisfactory and checks made with an impedance bridge confirm that a good match is obtained at the driven element. When using balanced line it is necessary to keep the line taut, otherwise some fluctuations in forward and reflected power may occur with movements of the feeder. Details of the delta match are given in Diagram 1.

All directors – cut from 1/8 in. diameter aluminum welding rod.
Driven Element and Reflector – cut from 1/8 in. diameter brass rod.
Spacing of Fiber Cords – 14 in.
Design Frequency – 144.2 MHz

Driven Element	38.4		
Reflector	43.0	12.3	20.5

Note: The reflector spacing has a slight effect on the radiation resistance of the driven element.
If maximum front-to-back ratio is required the length of the reflector should be adjusted while making actual measurement.

Table I. Dimensions and spacing for 32-element sly beam.

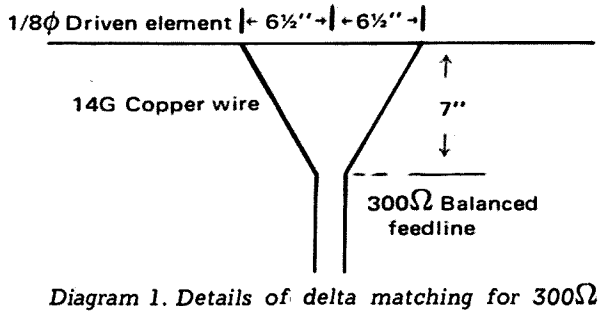

Diagram 1. Details of delta matching for 300Ω balanced feedline.

Fabrication

Even with the best artificial fiber cords available a small amount of creep inevitably occurs. A standard technique to minimize this is to prestretch the cords for 24 hours at about 90% of the breaking load. This is well worthwhile as about 80% of the ultimate creep will occur within the first few hours of loading, leaving only a small percentage to occur while the material is in service. The prestretching is conveniently done by placing two of the cords in parallel ready for the elements to be fixed and then tensioning between anchors as prescribed.

As an additional safeguard against creep it is recommended that when the sly beam is not in use the tension on its supporting cords be reduced to less than 50% of the working load. In practice, this is easy to do and only requires that the supporting cords pass through a pulley at the mast head and down to some convenient point from which adjustments can be made.

Two light wooden spacers about 15 in. long are used to maintain the cords at the correct spacing. These can be fixed to the fiber cords by passing the cords through small holes drilled near the ends of the spacers and then knotting the cords about the spacers.

It should be noted that the supporting cords are slightly elastic so that the spacing of the elements depends upon the tension applied. Also the sag of the array and susceptibility to lateral displacement in high winds is affected by the tension in the cords. It has been found that a total of 80–100 lb of tension in the antenna is satisfactory for a system employing two cords each of 120 lb breaking strain.

The elements should be cut to size and fitted to the supporting cords while they are subject to the intended working tension. Many methods of attaching the elements to the supporting cords are possible. However, wire ties should be avoided because of the risk of producing noise in the receiver due to the interaction of the unbonded metals. The simplest approach is to tie the elements firmly in place with a piece of cotton fishing line as shown in Fig. 2.

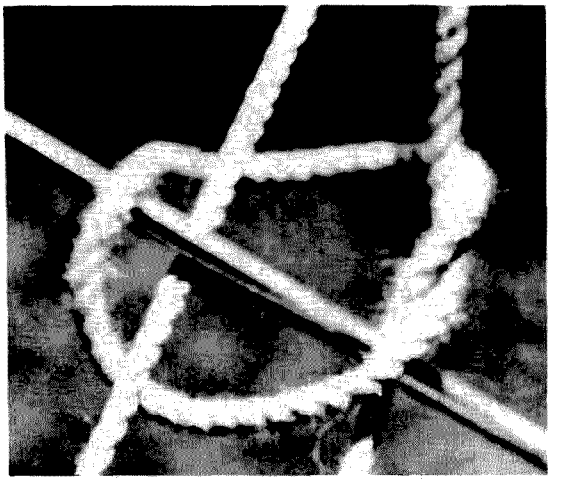

Fig. 2. Knot used to fix elements to suspension cords.

It is useful to arrange the knots so that they can be slid along the fiber supporting cords. The first step then is to tie all the elements in place and then working from one end slide each element into its exact position. A measuring stick with the leading dimensions marked on it simplifies this procedure. Knots are then trimmed and a drop of glue or varnish applied to hold them.

Masts

Two supporting points are required, one at each end of the array, and each of these must be capable of taking up to 100 lb of sideways loading. This sounds difficult but in practice is not really so. Use can be made of trees, chimneys and other natural objects although care is necessary to insure that the antenna's performance is not affected by objects within its effective aperture. If a tree is employed some arrangement is necessary to compensate for sway; otherwise the element spacing will vary. One solution is to use a pulley at the treetop and a counterweight which may rise and fall in a setup similar to that used for low-frequency longwire antennas. Even if two masts are required the cost need not be excessive. I used masts of 1½ in. galvanized pipe with three guy wires at every 10 ft of height. The guys used are

Improve your CW sending!

NEW AMECO CW MONITOR & CODE PRACTICE OSCILLATOR

■ Monitors Transmitter's CW ■ Transistorized
■ Kit or Wired ■ Built-in Speaker ■ Low Cost

The Model OCM is a combination Code Practice Oscillator and CW Monitor. It monitors your CW sending with a simple (no modification) connection to the keying terminals transmitter. It may be used with any transmitter or transceiver employing negative bias keying. A tone control, as well as volume control, and head phone jack are included on the front panel. Built-in back-to-back diode switching makes it unnecessary to turn the unit on and off, even when switching from CW to Phone. Current drain only takes place when the key is actually depressed. The model OCM contains one transistor and two diodes. Size: 6" x 3" x 2"

Model OCMW (Wired & Tested) (less batteries)
Model OCMK (Kit form) (less batteries)

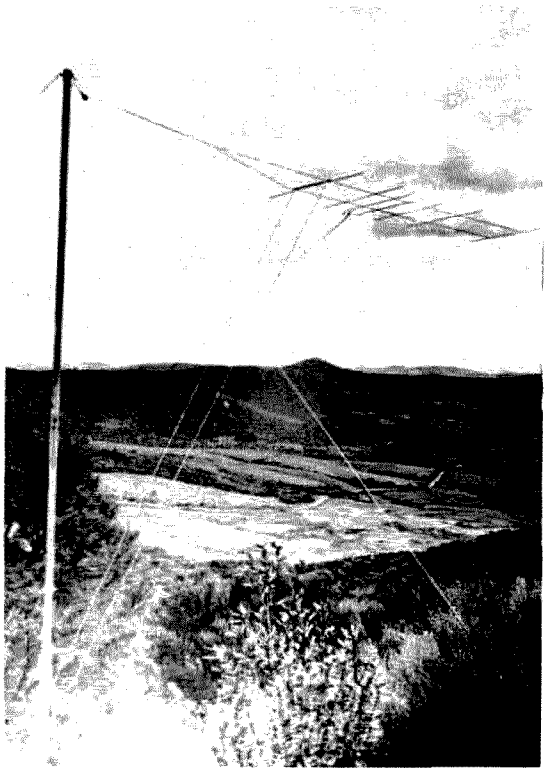

Fig. 3. The launching end of the "sly" beam.

10-gage fence wire, each fitted with a wire strainer for easy tensioning. With this arrangement there is no difficulty in obtaining the necessary 100 lb lateral load ability at 40 ft above ground, provided the guy anchors are firmly set.

Polarization

With the arrangement shown in Fig. 1 the two fiber cords are brought together to form a single cord at each end of the antenna. Generally the weight of the feeder is sufficient to keep the elements horizontal but in windy conditions the antenna may rotate, thus altering the plane of polarization. A simple solution is shown in Fig. 3. Two light cords are attached to the wooden spacer at the reflector element to maintain the desired plane of polarization of the array. A change from horizontal to vertical polarization or vice versa can be effected in a few moments by altering the relative positions of the two stabilizing cords thus rotating the array about its long axis.

Bandwidth

Generally speaking, the bandwidth of a yagi antenna is inversely proportional to the gain; for a 21 dB yagi, peak performance can only be expected over a narrow portion of the band. As normally defined, the bandwidth of the 32-element sly beam is probably about 0.5 MHz at 2 meters. Outside this range a noticeable drop in performance is expected. However, the sly beam has an unusual feature not found in conventional antennas: The supporting cords are quite elastic and by altering the tension on the beam it is possible to alter the spacing between adjacent elements. This *en masse* altering of element spacing tunes the array and has the effect of increasing the useful bandwidth of the antenna. It should be pointed out that to achieve maximum gain at a particular frequency the spacing between every element and the length of every element must be optimum.

Gain

Some authorities do not state performance figures for antenna arrays because of the uncertainties involved. However, I consider that an indication of the potential performance should be given so that different arrays may be tentatively compared. Provided the readers realize that many factors such as antenna height and multipath reflectors can markedly affect antenna performance, no serious disputes should arise.

The theoretical gain of the 32-element sly beam is close to 21 dB when compared with a dipole. Many weeks have been spent in attempting to verify this gain figure experimentally but a reliable and accurate figure has not been obtained. On-the-air comparative tests using a dipole and a 5-element yagi generally support the theoretical gain figure. The antennas used for comparisons were carefully checked for impedance matching and resonante frequency. Measurements were made with the aid of a reliable stepped alternator fitted between the converter and tunable i-f system. Tests were conducted from two sites under a variety of conditions with stations up to 180 miles distant. The improvement obtained with the sly beam over the 5-element yagi on receiving tests was typically 2 5-units, or 12 dB.

On the long path between Dunedin and Wellington (370 miles) the sly beam has shown its superiority. On December 14 when Bill (ZL2CD) was in contact with Peter (ZL4LV) and ZL4TAH (me), Bill's signals were barely perceptible on a 5-element yagi at my Pigeon Flat DX site. On the 32-element yagi Bill's signals were easily readable.

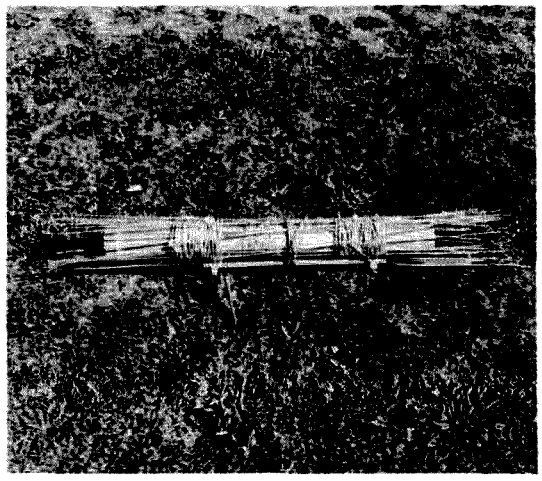

Fig. 4. A "sly" beam can be rolled on to a cardboard tube for transport.

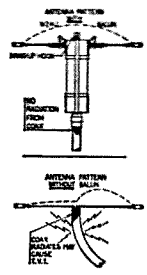
Portable

Because the sly beam has no rigid boom, it can readily be rolled into a cardboard tube for transport to field day or DX sites. The total packed weight of the 32-element beam, excluding feedline, is about 2½ lb.

Usefulness



Obviously the sly beam is not intended for across-town contacts. With a simple antenna, such as a 5-element yagi, it should be possible to consistently work stations out to 100 miles or more, given average conditions and moderate transmitter power. If you cannot do this, fix your gear first or find yourself a good portable operating site, then think about building a sly beam.

For most DX purposes the fact that the array is fixed in direction may be of little importance. The 32-element beam described here has a beamwidth in the "E"

plane of about 10° (at the half-power points). Thus at 200 miles the width of the main lobe is about 34 miles. My long yagi at Pigeon Flat near Dunedin has been carefully aligned so that the centerline of the main lobe passes close to Wanganui in the North Island. In the region of Wellington the main lobe (when it gets that far) would be 75 miles wide. Thus Christchurch, Wellington, and Auckland all lie close to the 10° solid angle enclosing the main lobe of the antenna on its present heading. In addition to the dispersion of a signal with distance, resulting from the diverging antenna beam, there is scatter due to topography and atmosphere. All this means that beyond 200 miles the area over which the transmitted signal will be heard and from which signals will be received is quite broad.

Future Development

Although the suspension system appears best suited to the yagi, it could readily be adapted for collinear or other types of array. Even with the yagi there is much scope for experimentation and development. An accurate measure of the gain of the sly beam and an assessment of the broadening of the bandwidth achieved by altering the tension of the suspension cords would be worthwhile projects.

A quick glance at Table I, which gives the length and spacing of elements, shows that apart from the reflector, the driven element, and the first four directors, the element length and spacing is constant. If a reflector, driven element, and set of launching directors were fitted to each end of the array, a switchable bidirectional antenna might result. This could prove handy for ZL2s who could then beam north or south simply by feeding the array at one end or the other.

Conclusion

The sly beam is an exceptionally high performance antenna which can be constructed in a single afternoon from all new materials for less than $10 (excluding feeder and masts). No special tools or fabrication techniques are required and anyone who can tie a knot could construct one. Unusual features of the suspended beam are its ability to be tuned by varying the tension on the supporting cords, its high gain resulting from its length, and its portable nature. It is best suited to fixed-direction communication beyond 100 miles and should make possible some rare DX communication on 2 meters and perhaps even a record-breaking contact between a first and fourth district station.

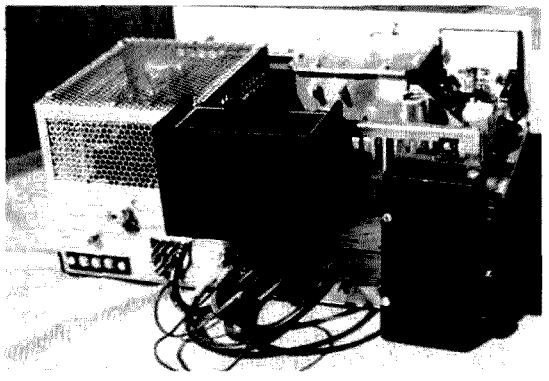
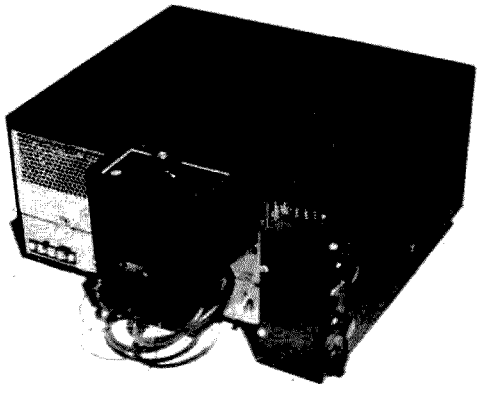
Installing the Swan 250-C Noise Silencer

Installing the noise silencer in the Swan 250-C can be a problem if it is done according to the factory directions. Their way requires the noise silencer to be disassembled every time the transceiver's top is removed. They're probably hoping that the purchaser will never have to open the top – except every couple of years or so to change a tube – however, this is not necessarily the case.



Inside view of 250-C showing the two bolts to mount the noise silencer (the other one is just right of the electrolytic).

I installed the silencer on the back of the unit. There was already one hole drilled there; careful planning will enable you to place another hole at a critical spot for two-point mounting.



Be careful not to mount the silencer snugly against the transceiver or the top won't fit on. An extra nut on each screw will act as a spacer providing the necessary clearance.

There is all sorts of wire left over which could probably be cut off. I just wound it up in a circle so as not to be bothered soldering connectors. Be sure to remove the jumper wire inside the transceiver between the IN and OUT jacks.

Back of unit after mounting silencer.

This silencer works quite well on silencing ignition-type interference that seems to be the curse of all 6 meter operation, but is ineffective against the "solar noise" that comes and goes.

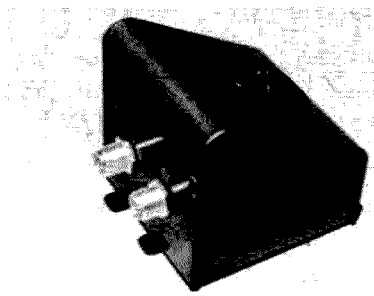
Back of unit after completing work. Wires probably could be shortened.

This silencer is also sensitive to any stray rf that the antenna picks up. There are three other 6 meter men within six miles of my home – this device will detect the rf and send it to the speaker whenever they operate, even if (especially if) I'm not tuned to the same frequency. The other day a police car drove by with the radio in operation, somewhere between 40 and 50 MHz, and it picked that up. The Swan factory advised me there was no way to eliminate that problem – inherent in the FETs.

Installing the noise silencer on the back of the unit makes it convenient to remove the top for service, does not distract from the appearance of the equipment; and it is no great problem to reach back there to turn on and off if you remember to keep the knob up.

Front view of completed project. Be sure to line top of silencer with top of transceiver.

Measuring RF Output



So your new Bandjammer 5000-Q is rated at 752W peak power. Big deal. How much of this is getting out where it counts?

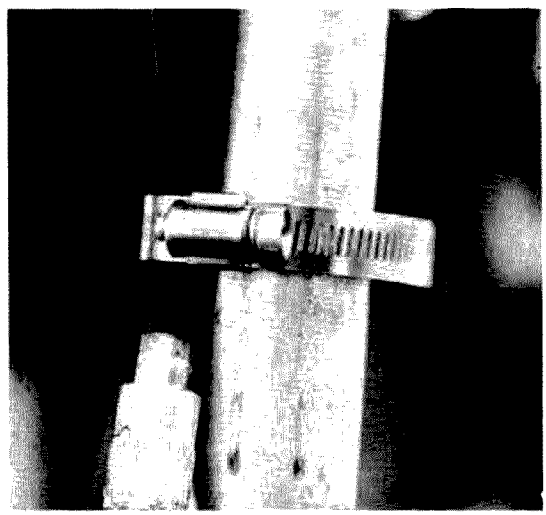
It's easy to find out by inserting an rf ammeter in series with the line. A more exact reading would be to have the rf ammeter at the antenna input terminals, but that might be impractical when it comes to reading the meter (although you could put a diode there and a remote-reading meter in the shack).

Recently I found an rf ammeter at one of the mail-order surplus houses for $2.95. I installed this in a little cabinet, put two coax connectors on the back (in and out) and now can read rf current in the line, into the dummy antenna, or wherever it is going.

Inside wiring is extremely simple. Note ground wire installed to insure continuity of the shield circuit.

The completed instrument showing the coax connectors on the rear.

Remember the formula $P=I^2R$? Square the reading on the meter, multiply by the impedance of the line you're using, and you have the power past that point. At the antenna, you could determine the antenna resistance and take the current reading at that point.



When tuning up the rig, place the ammeter on the antenna side of any tuning or matching devices and tune for maximum current.

It's amazing to learn how much (or how little) current these rigs produce. For instance, my Swan 250-C puts 1.35A into a 50Ω line. My friend's SB101 from Heathkit put out 0.7A until we worked on the antenna – then it put out about 1.25A. My Heathkit SB401 puts anywhere from 2 to 0.6A into a 50Ω Cantenna, depending on what band it's on.

Commercial stations determine their power by the antenna current. Knowing the antenna resistance at the operating frequency, they multiply that by the current squared. If the antenna resistance is 62½Ω, 4A rf would be 1 kW into the antenna. 126.48A would be 1 MW.

Remember the ammeter does insert a little reactance in the line (I never leave it in all the time), and the calibration changes with frequency, although you can tell what side of the ballpark you are on. An rf ammeter in the shack makes a nice piece of test equipment.

Useful Cable Clamps

Radiator hose clamp used for coax-to-mast application at WA6CPP.

After using plastic tape to hold coax to mast, and after having a big mess trying to undo the tape, I came up with the idea of using automotive radiator hose clamps to hold the coax to the mast.

These clamps are available at almost any automotive supply outlet or discount store, come in a number of sizes, and are relatively inexpensive.

Several coax lines can be held with one clamp.

The worm gear does not loosen in time and holds the coax securely. Be careful not to tighten down too far, however, as it could cause a problem in the future. Just "ease down" until the cable is snug.

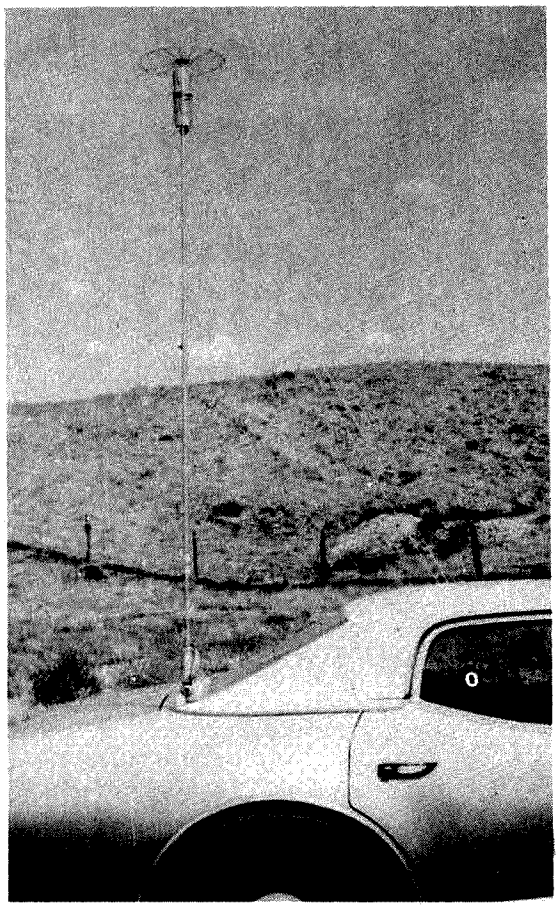
WA6CPP ■

1/4 TOP-LOADED MOBILE ANTENNA

. . .an efficient short 1/4 wave twenty meter dipole

Henry W. Strege W5AZE

Increasing the efficiency of a mobile antenna has always been a worthwhile project to me, especially so, after reading the first paragraph of the article, *The W8 High-RF Short Beam,* by David L. Walsh W8HRF, in the Feb. 1969 QST. This paragraph shows how a short dipole can be made more efficient by end-loading with a coil and capacitive hat: The radiation resistance is increased while the coil losses are decreased. An illustration on page 496 of the 1969 ARRL Radio Amateur's Handbook shows why more power is radiated with this type of antenna. Note the ground-loss resistance is given as 10Ω or more in the above reference. The W8HRF article applies to a ½λ dipole. I decided to try this idea with a ¼λ 20 meter mobile antenna, which is 7 ft 4 in. (including the antenna mount on the car).



Comparison

My commercial antenna has a continuously variable coil, adjustable from 3.8 MHz to 29.0 MHz. Both antennas were adjusted for resonance at 14.235 MHz. Reports from different parts of the country, including one from the Hawaiian islands, indicated that the top-loaded antenna is one S-unit better than my commercial antenna. This difference was obtained by checking each mobile antenna with the trap vertical on the house, switching quickly from one to the other, to avoid fading effects. The two mobile antennas were interchanged on the car near the house, fed through 75 ft of coax cable from the base station. The commercial antenna was down two S-units while the top-loaded antenna was down only one S-unit from that of the house antenna. The transmitter PA current changed only 7% when switching antennas, which would not significantly affect the results. This 6 dB gain should be equivalent to increasing the transmitter output by a factor of about 4. This is a cheap and easy way to increase power output as well as receiving ability.

The top-loaded antenna is a little top-heavy and needs guy cords or light ropes to keep it from leaning back or swaying out from the car. I used two nylon cords, anchored at the coat hooks above each rear window, passing through the top of each window to the bottom of the coil. At speeds of over 60 mph a low howl can be heard; however, a person usually slows down when using the mobile rig.

Input Impedance

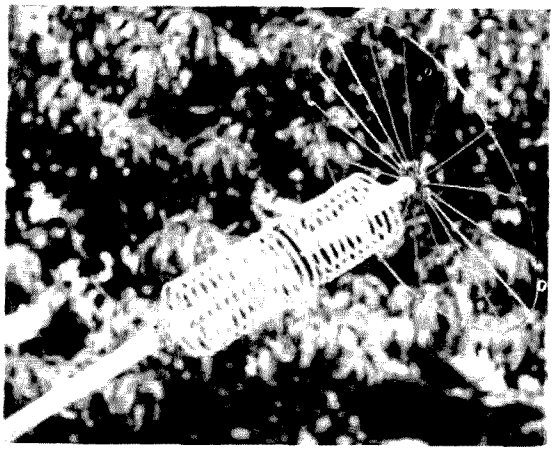
To find out how much the radiation resistance was increased, an rf bridge was

constructed similar to the one described in the article, *How to Hang d Dipole*, by James Ashe W2DXH, in 73, May 1968. The input impedance of the commercial antenna was measured as 30Ω and that of the top-loaded was 42Ω; both antennas resonated at 14.3 MHz. This would indicate a 12Ω increase in radiation resistance, as the ground-loss resistance would not change appreciably for the two measurements. The coax feedline was disconnected from the antenna, and the rf bridge connections were made as short as possible – in my case, 3 in.

Construction

The construction of this antenna is similar to that used in the W8HRF article except I used only half the driven element. I used a 12 in. capacitive hat from a previous project, with 16 spokes made of 12-gage hard-drawn enameled wire. With the total length of the ¼λ dipole, the required coil was made with 25 turns of 9-gage aluminum clothesline wire (2½ in. outside diameter and 8 in. long). I made this dipole in two sections so that it could be dismantled and carried in the trunk of the car. I used ½ in. aluminum tubing for the bottom half and a slightly smaller tubing that would slide inside for the top half.

One of the two sections was made 3 in. longer to allow for telescoping. For the insulating section I used a 5/8 in. wood dowel trimmed at the ends so it would make a tight fit 1 in. into the top half of the dipole and into a 1 in. piece of ½ in. long tubing. Two opposing sections were cut off and the other two sections were bent in at right angles, one over the other. In the center of this bent-over section, a hole was drilled and tapped for a 10-32 bolt. A 1 in. long bolt was inserted and threaded through from the open end of the tubing before being fitted over the wood dowel.



It is advisable to secure the dowel inserts in the tubing with small bolts or screws.

Before mounting the coil the wooden insulating section should be given one or two coats of shellac and after thoroughly drying, one coat of marine spar varnish should be applied. This should keep the moisture out for a long time. One end of the coil was formed into a small loop to take the 10-32 bolt; the other end was straightened out to lie parallel to the aluminum tubing.

The loop end of the coil and the capacitive hat were put on the 10-32 bolt at the end of the insulating section and fastened with lockwasher and nut. The insulating section should be centered in the coil. The other end of the coil was fastened to the aluminum tubing with a small stainless steel automotive hose clamp, available at most car repair or filling stations.

Four equally spaced slits, about 2 in. long, were cut at one end of the bottom tubing section, the one with the largest diameter. The two sections of tubing were then telescoped together for about 3 in. and clamped with another stainless steel hose clamp. The junction was marked so that it can be assembled again to the same length.

This type of construction allows the antenna to be taken apart and carried in

the trunk of the car when not in use. The bottom of the antenna was fitted with a bolt which would fasten onto the antenna mount on the car. The center of the coil should be supported as suggested in the W8HRF article. I used two small Bakelite strips fastened with small wood screws to the center insulating section. I tied the coil wire to the Bakelite strips with fishing line through small holes drilled near the ends of the strips and covered them with coil dope.

Adjustment

With the antenna fastened to the antenna mount on the car and the feedline disconnected, a small half-turn link was connected between the bottom of the antenna and one of the mounting bolts on the car body. A grid-dip meter was used to check antenna resonance. The coil was adjusted by moving the hose clamp, at the bottom of the coil to spread or compress the coil until the grid-dip meter showed resonance at the chosen frequency With the meter left in the dip position, the frequency should be checked on the station receiver for a more accurate reading.

I found a small change in the position of the hose clamp gave a large frequency change. I bent the end turns a little for the fine adjustment after making the coarse adjustment with the hose clamp. Other adjustment procedures using an swr bridge or a field strength meter can be used to tune the antenna to resonance. The swr reading changed very little when the frequency was changed from 14.2 to 14.3 MHz.

DUAL GATE MOSFET

PRE-AMPS

to 175 MHz. $21.95 ppd.
to 300 MHz. $25.95 ppd.

NEW FOR 1970!
The above models now have rf gain control.

For 300 to 470 MHz
See Model 202 in our catalog.

- **Available from 5 MHz. to 450 MHz. Bandwidth is approximately 3% of frequency.**
- **Voltage gain 30 to 40 DB depending on frequency.**
- **Two Dual Gate MOSFET amplifier stages with each having a tuned input and tuned output. Each Dual Gate MOSFET is actually an integrated cascode circuit thus giving you 2 cascode circuits equivalent to 4 triodes.**
- **Exceptionally low noise (2.5 DB at 175MHz.), greatly reduced cross modulation and 10 times the dynamic range (signal handling capability) of the best bi-polar transistors. Also superior to preamps using junction FETs and Single Gate MOSFETs.**
- **Internal connections for high impedance AGC or manual gain control if needed.**
- **Type BNC input and output receptacles for minimum loss at UHF. Standard impedance is 50-75 ohms.**
- **Carefully tuned at our laboratory with sweep generator and oscilloscope for the best bandpass characteristic.**
- **Full wave UHF diodes protect input transistor.**
- **Operates on 6 to 16 volts DC, 5 to 15 Ma.**

New York City and State residents add local sales tax.

11 ELEMENT 2 METER CIRCULAR QUAD

Ralph W. Campbell W4KAE
216 Mariemont Drive
Lexington KY 40505

The 11-element version of the long circular quad is designed for operation on 144 MHz up to about 146 MHz. Measured horizontal forward gain showed 15 dB gain over a dipole. Front-to-back was 21 dB for the horizontal pattern ratio (and not the vertical directivity of that pattern); and I measured 9 dB over a dipole for the vertical forward gain, and 12 dB vertical front-to-back. Measurements were made on the linear scale of the SX-122 S-meter that was modified for elimination of contact-potential bias effects, and with increased control of i-f amplifier cathode current (meter electrical zero). By using a Parks Electronics' Lab Converter plus a JFET preamplifier, linearizing of the S-meter scale on the low end was obtained. These measurements are repeatable. An International Crystal secondary frequency standard provided the transmitting signal source on exactly 144.00 MHz, from a seventh-overtone crystal. The transmitting antenna was a simple ¼λ groundplane that could be turned vertical or allowed to radiate horizontally, depending on the relative position of its case. The 11-element long circular quad was operated as a

receiving array for these tests. Antenna height was 70 ft above flat ground, thereby eliminating ground reflections.

Theory of the 11-Element Circular Quad

Initial measurements – made by an organization having ties with Project Oscar – showed 18 dB gain over isotropic (not over a dipole), since the pattern was obtained while my antenna was *transmitting* on 1000 MHz to a reference antenna receiving the signal. I am very grateful to those who made the tests possible; however, there is one point that should be cleared up: There is vertical polarization in the major lobe, which means some circular is generated. Repeatable tests have shown – on this 2 meter model – that with 11 circular group-phased elements there's 9 dB/dipole forward gain on 2 meters; and 12 dB/dipole front-to-back for the vertical pattern! According to WØHTH, some circular polarization is always present in most common antennas. If you try to test your own antenna, remember that the structure under test cannot be operated in the transmit mode for reliable readings. Grouping the elements as shown in the photographs boosted horizontal receiving-mode gain by as much as 5 "real" dB on the 18-element structure. At present, the gain of an 11-element circular quad is 15 dB/dipole, with an estimation of 18 dB/dipole possible with 18 properly phased (*not* like a yagi) elements.

Screen size is also a factor in reconciling gain expected with actual measurements. As you increase forward gain, front-to-back tends to decrease, with any major improvement in the forward lobe. This doesn't hold for yagi arrays, for example, since adding extra elements to make it "long" reduces the overall efficiency to such an extent that a slight increase in forward gain is the only effect. And, by adding even more elements, considerable power is dissipated as element "heat" if we could measure it! This is where I stopped further research and developed "driven" parasitic director groups. Getting back to screen size, you can expect an increase of 2 dB by increasing screen size from 4 to 8 ft

Fig. 1. This photo shows the completed 11-element 2 meter circular quad. Screen size is only 4 ft, and found to be inadequate, unless it could be increased to 200 inches. An 8 ft diameter screen reflector would have cost $48 for materials alone! Forget about "chicken wire" and you'd need a "cherry picker" for hardware cloth, because of the weight.

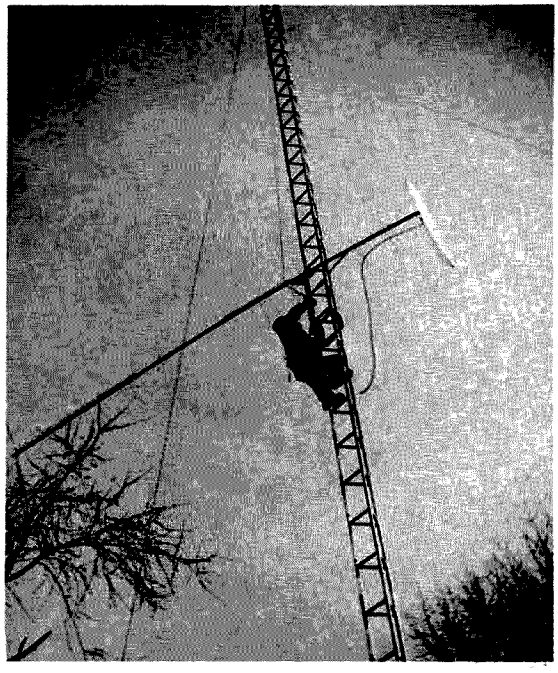

Fig. 2. Carl Day made 2½ round trips before final ground readings were taken as being acceptable.

diameter; however, I would expect front-to-back ratio to increase to only 24 dB. Hopefully, the horizontal forward gain would be 17 dB/dipole!

Construction

Figure 1 shows the completed 11-element 2 meter quad. The boom is made of thin-wall aluminum TV mast and is quite strong. The screen is a braced, two-part structure covered with half-inch Macklanburg-Duncan "expanded aluminum" mesh (chicken wire won't do!). The top set of guys is attached at the 60 ft level.

Figure 2 shows the antenna man's position at the 40 ft level; and the tower is back-lighted nicely against a darkened sky. This photo shows most clearly the connecting tower bolts and the aluminum *Foamflex* transmission line taped to it. Note especially the slipknot of rope around the first director in the first (common) group. You can see the element wiring if you look closely

Fig. 3. Seen here is one of those crucial moments when "you don't know if he can make it but you don't dare ask!" Since this was a success with a 4 ft screen, a later modification to include a driven, reverse-phased aluminum element certainly made the job easier.

Figure 3 shows perhaps the most hazardous or in-between position of the tower and 11-element quad. He made it! (But I had some doubts because of guy wire breakage the day before.) The top of the gin pole is at 80 ft. I was on the ground pulling up on the line streaking down to the left. This shot is included in the article to show how a steeplejack or tower construction man can safely erect this antenna. Incidentally, boom length is 21 ft and screen diameter is 4 ft.

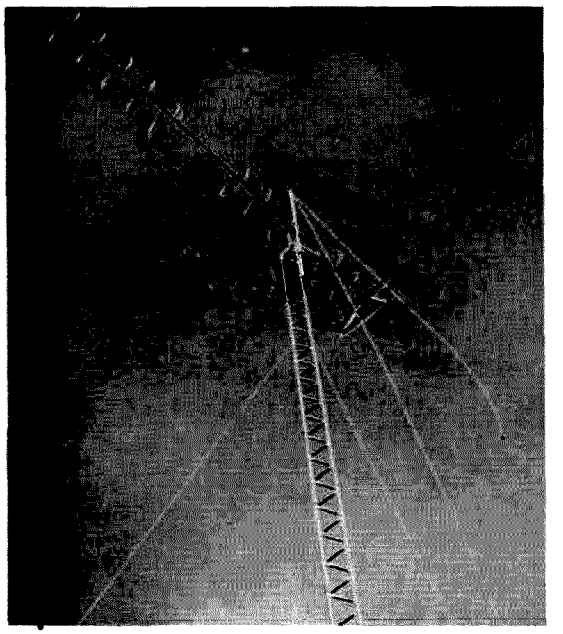

Fig. 4. The array is in position, with ropes gleaming in the sunlight. Use of a rugged gin pole is an essential.

Figure 4 is a dramatic one. With erection lines streaming in the wind Carl Day is tightening down the mast bolts prior to connecting the RG-8/U to the aluminum *Foamflex*. We used a Dill Tower TV tower for a rugged $10-per-section mast. Rohn 1¼ in. heavy galvanized mast is used to rotate and support the 11-element quad.

Figure 5, a closeup of the driven-element connections, reveals the screen-mesh structure. The round 9 in. flat plate is connected to the aluminum A-frame struts. The plate is made from M-D yellow brass. Plate-to-boom attachment is accomplished using right-angle shelf brackets which are thoroughly bolted to the boom with 3/16 galvanized roundhead machine screws. Rivets are used to hold the screen to the A-frame. From this position we can also see where the boom was electrically broken

with an external nylon sleeve; this was to prevent irregularities in the antenna's pattern; however, it was not found to be completely necessary. Figure 5 also shows a *Cushcraft CL-116* collinear element block. These circular elements were bent in a local sheet-metal shop. Sufficient care must be used to prevent breaking the mounting block (especially when straightening an already mounted loop). Connections to the block are made with 200Ω *Federal Wire and Cable* transmitting twinlead. The other end of the twinlead goes to a *Sound & TV Systems* 4-to-1 ferrite-core VHF balun. The balun is wound on an IRN-9 core, available from *Permacor* Division of Radio Cores. I used 14-gage wire for the windings, insulated with shrinktubing on the inside. The wound core is next encapsulated with GE silicone rubber. The encapsulated balun is then housed in a large rubber *Muellar* boot and taped thoroughly. The vswr is unity at 144 MHz; it rises to about 1.5 to 1.0 at 146 MHz. The *Cushcraft* collinear elements need to be shortened 2 in. off each *reflector* half-loop plus an additional length for the distance from block terminal to block terminal. An inch off each Cushcraft *driven element* is all that is required for the 38 in. elements.

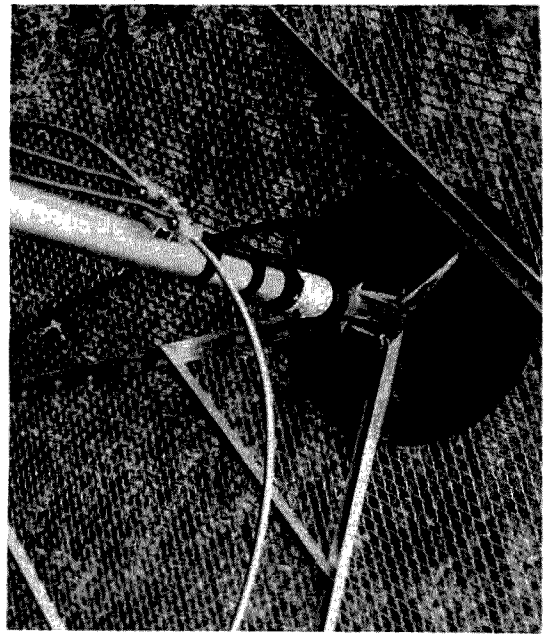

Fig. 5. In a later version of the same 11-element 2 meter circular quad, the screen reflector was cut off the hind portion of the boom, and an extension of the boom was made to allow the new reflector to have proper 19 in. spacing from the first driven element.

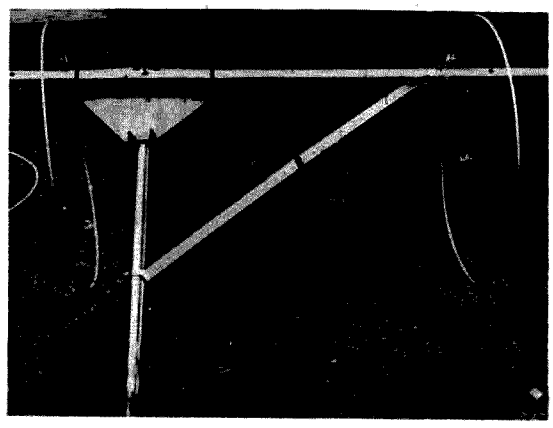

Fig. 6. Detail of the insulated strut from mast to boom. Notice the element ends. Mounting and physical connections with these elements are critical! (Loc-Tite nut and stud lock is mandatory for holding screws in place, unless you have stainless-steel lockwashers.)

Figure 6 shows closeup of the elements, brass gusset plate, and the electrically broken boom-to-mast brace. The gusset plate is patterned after another design except that it is made of brass and not ¼ aluminum. Another improvement is that there's a bolt all the way through both the masting and the boom! Muffler clamps are also used, instead of the usual clamp. Since our mast is smaller than the boom, a piece of scrap rubber garden hose serves to bind these surfaces. The broken boom brace is a piece of scrap aluminum 1/16 in. angle, riveted to a solid PVC block.

Each end of the Cushcraft circularly bent elements is butted against each other inside a steel ¼ in. shaft coupling previously drilled through with a 1/8 in. bit. After drilling, element half-loops are inserted about midway, drilled in place, and riveted. This is the only way I could find to rigidly connect elements without breakage.

The driven elements are 76 in. diameter, with allowance made for block-to-block spacing. The first group of directors are all

cut to have an overall circumference of 72 in. The second group of directors all have an overall circumference of 68 in. For a given constant in inches we can arrive at a formula which we divide by frequency in MHz to get the correct lengths. (Slide rule accuracy is all that's necessary.)

Driven Elements	1st Directors	2nd Directors
$\frac{11,050}{F_{MHz}}$ = ans. (in.)	$\frac{10,375}{F_{MHz}}$ = (in.)	$\frac{9,800}{F_{MHz}}$ = (in.)

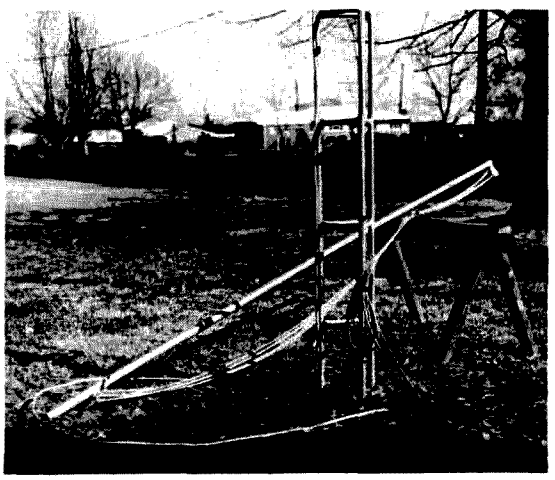

Fig. 7. The aluminum Foamflex transmission line (shown here above-ground) has been buried in a shallow trough; now I have a good crop of Kentucky bluegrass over it.

Figure 7 shows erection equipment, rope line for the gin pole, and a closeup of the bottom section as it attaches to the Dill Tower "Pickle" base. I like to call it the "mud base" because all you do is dig a 4 ft hole in decent soil, then slide the base into it and refill with mud; all the while mixing in water from a garden hose. Let the mixture set for several hours and periodically check the vertical angle with a carpenter's level. If you let the mixture become completely hardened, it is possible to erect up to 4 tower sections, without guys! Always guy at least the 20 ft section before going further. Another advantage of the Pickle base is that it may be left in the earth, should you decide to move, and the other tower sections can be saved for a new site.

Amateur Use

Successful use of the 11-element circular quad dates from the first evening it was compared with my 28 ft L-matched yagi. Both the quad (boom length just over 20 ft) and yagi had the same forward gain. However, the yagi canceled out vertical 2 meter signals just as effectively as if the coaxial cable was disconnected from the receiver! Not so for the round quad. (I will be glad to demonstrate this test to any 2 meter mobileers.)

Here in Lexington, Ky., we have had no recent stratobending band opening to fully evaluate the array's performance with DX. However, it receives the usual 75 mile groundwave signals better than the 28 ft yagi. Scatter pickup is at least 3 dB better (by the ear). Curiously enough, "coaxial cable noise" was first noticed with yagi in comparison to the circular quad. After repeated checks as to carrier strength at 75 miles, with antennas at the same height, it was obvious to reporting stations that the horizontal forward gain was equal. The important difference between arrays is that my RG-9/U silver-plated coax was much noisier than twice as much aluminum *Foamflex* cable, fed to the equal forward-gain antennas! Receiving signal strengths favored the quad. Perhaps the most overlooked point in antenna design is reduction of fading. With a circularly polarized antenna fading is less – but never eliminated without a complicated VHF diversity feed. But the 11-element round quad is a step in the right direction.

Conclusion

Although I do have a patent pending on the long circular quad, I feel that since it is a breakthrough in antenna design, it should be passed on to the amateur fraternity. The only yagi characteristics this array has is in shortening each group of parasitic directors. There are many new variations which I see possible, like group-phased half-wave parasitic elements, a driven reflector within the first group, and "squaring" the round elements to make a "top-vertex-fed" conventional quad. Top vertex feed on each full-wave element would probably eliminate the vertical pattern and boost the gain!

E.R. Shepherd ZL2ASJ
105 Mayfair Ave.
Hastings, New Zealand

THE "663" BEAM

...for 10, 15, and 20 meters

The varying degrees of success I have attained with beams using loaded elements, trapped elements, compromised matching networks, and tuned lines led me to a project which resulted in the design and construction of a beam - an efficient three-band beam for 10, 15 and 20 meters.

One of the primary design goals was a beam that would give performance comparable to three individual yagis: the result was a 3-element antenna on 20m and a switched 6-element collinear array on 15 and 10m. Full 6-element beams show higher gain figures, of course.

Necessary prerequisites were:-

- A single coax feedline with low SWR
- All elements in use on all bands
- No high-Q traps or stubs
- Manual band-switching by remote control
- Must be full size on the lowest band

The completed beam is no bigger than a full size 20m 3-element yagi on a slightly shortened boom (this is the only compromise and does not affect the bandwidth on 20m). Viewed from ground level it appears to be a mono-bander. The "663" title is derived from 6 elements on 10, 6 elements on 15, and 3 elements on 20m.

Mechanical

The mechanical construction is quite straight forward. Two lengths of wood forming the boom are 2 x 1½ in. x 16 ft long; the cross spars for mounting the elements are 1½ x 1½ in. x 9 ft long. Try to obtain straight-grained wood with no knotholes or splits, and apply many coats of the necessary weatherproofing agents. The woodwork is bolted together with ¼ in. galvanized coach bolts. As each of the elements is split in the center, 4 insulators are required on each spar. The insulators are those used for mounting bus bars in switchboards; they are attached to the spars with heavy brass wood screws.

All metal parts should be galvanized steel, brass, or aluminum; and remember that you can put galvanized steel with aluminum but NOT brass or copper, due to corrosion. The elements are Dura tubing, tapered in three steps commencing at 1 in. diameter and reducing to 7/8 in. and then to ¾ in. for the end tips.

Where the elements telescope together they are slotted and hose-clamped. Similar clamps are used for mounting the elements to the insulators.

The boom is braced with 4 struts back to the main support pipe or mast made from ¾ in. galvanized conduit 6 ft long. Top guying of the boom could be employed instead of the struts. The remainder of the mechanical construction is obvious from the photographs and it can all be assembled from readily available parts.

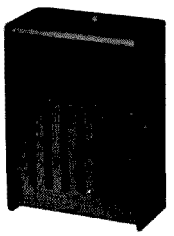
Mounting of the beam to the tower or mast is left to the builder. Mine is a two-point mount thus enabling the boom to be tilted over one way or the other for adjustment or maintenance.

Electrical

The heart of the whole triband feature is the various switched networks inside the weatherproof boxes in the center of each element. These boxes are plastic containers with airtight lids as used for storing food in refrigerators and are available from most stores for about 60¢ each. Each box has a ¾ in. diameter vent in the bottom covered with plastic gauze.

All capacitors are isolated from ground by mounting straight to the plastic case for the radiator tuning unit or on strips of polystyrene for the parasitic elements as evidenced in the photographs. All the capacitors are adjusted at full height so an 8 ft length of 1 in. dowel is used as a long trimming tool to reach the capacitors on the director and reflector. The capacitor shafts have a flat filed on them to match an adapter on the end of the 8 ft dowel. On 20m the 3 large ZC1 type relays (RL1) are energized, thus sorting out the parallel networks in all elements, and in the case of the driven element, connects the coax feedline to series capacitor C3 on the 20m omega match. (Although this setup looks like the conventional gamma match, it is actually an omega match due to the stray capacity in the tuning box.)

The tuning of the beam on 20m is determined entirely by element length and these were taken straight from Bill Orr's Beam Handbook with slight reductions to allow for length of the ZC1 relays and connecting braids. The element lengths are as follows:



Director – 30 ft, 9 in.
Radiator – 32 ft, 10 in.
Reflector – 34 ft, 8 in.
Matching rod – 36 in., 3/8 in. diameter, spaced 5 in. center to center from radiator.

Series capacitor C3 is a 150 pF transmitting type. All elements have a gap of 4 in. at the center. Referring to the diagram, note that RL1 (b) contacts seem to be unnecessary, but utilizing the coil center-tap for the earth return to the coax gave odd reactive effects, so the coil was shorted out in all directions possible with the available relay contacts.

For operation on 10m, all the relays are left open, leaving a parallel-tuned circuit across the center of each element. The coax feedline is then tapped across one turn of the radiator coil by the changeover action of RL1 (a).

The position of the tapping point can be varied to suit the impedance of the coax and no series reactance capacitor was found necessary. The tapping point was found to be the same for 10 and 15m, one turn being the case for 50Ω heavy duty coax. Operation on 15m is achieved by

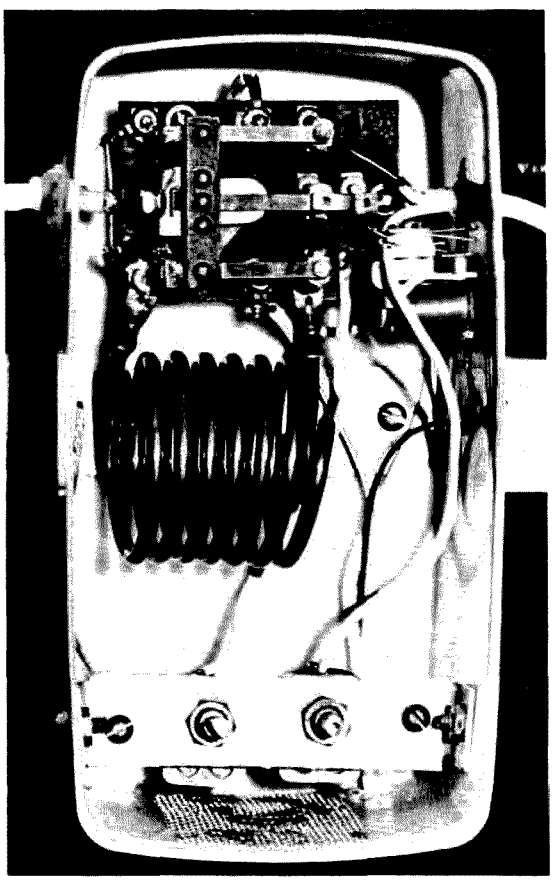
James Research company, dep't: AR-M
20 willits road, glen cove n.y. 11542

energizing the three relays (RL12), connecting capacitors C2 across the existing 10m LC network.

The coils are wound with 3/16 in. diameter copper tubing, 2 in. internal diameter, spaced 3/16 in. between turns. The director coil is 7 turns, radiator coil 5 turns, and the reflector coil 8 turns. The radiator coil is smaller than the other two due to the longer connecting leads.

The parallel capacitors C1 and C2 (6 altogether) should have a capacitance of 30–40 pF.

The coils of the three ZO1 type relays (RL1) are wired in parallel requiring 12V dc at 600 mA. Likewise, the RL12 relays are parallel connected, requiring 24V at 300 mA. The two voltages are furnished by the one simple supply using a TV vertical output transformer and bridge rectifier. A 100 μF, 25V electrolytic capacitor is necessary across the output of the supply to eliminate relay chatter.



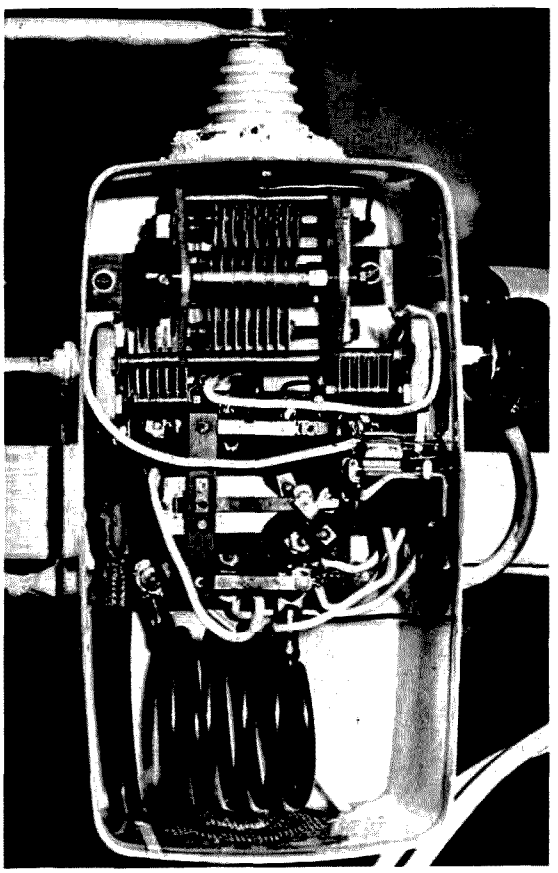
The relays used are war surplus items and can be replaced with more modern types. Five of the relays are spst. The RL1 relay in the radiator requires a 1-pole changeover and dpst contacts.

The switching sequence is as follows:

10m – all relays de-energized.
15m – RL2 relays only energized.
20m – RL1 relays only energized.

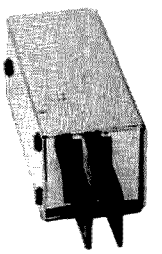
Tuning Up

The initial tuneup is at about 6 ft above ground just to ascertain that the various LC networks will cover the correct frequencies. The final tuning must be done as near as possible to full height – and takes up most of an afternoon! The setup was as follows: an swr bridge was in the feedline at all times; a remote dipole with the voltmeter extended back to the shack was used; a telephone from the shack to the top of the tower was most useful. All adjustments were done for maximum gain (front-to-back ratio was best at these settings) as measured on the dipole voltmeter; this naturally coincided with the lowest swr readings.



Director and reflector tuning unit.

Tuning is started at 20m by closing RL1 relays only. Check that the radiator is resonant on 14.2 MHz with a grid dipper, and if possible check the frequencies of the director and reflector to ascertain that they



are just above and below the 20m band. An rf carrier on 14.2 MHz is applied to the beam, then the matching rod length and series capacitor C3 adjusted until the swr reading is nil. Front-to-back ratio can be checked and will be found to be about 25 dB. This completes the 20m tuning.

The next step is to deenergize all relays and apply an rf carrier on 28.6 MHz. Adjust the C1 capacitor starting with the radiator, then director, and then reflector for maximum gain on the dipole voltmeter. It pays to go over these adjustments at least twice to get best gain. Front-to-back ratio on this band is about 35 dB. Maximum gain will coincide with minimum swr, but if a complete null is not evident, move the radiator coil tap slightly one way or the other.

Driven element tuning unit.

the permaflex key

- both a twin lever & straight hand key in a pivotless 2 paddle design.
- gives instant choice of automatic semi-automatic & straight hand keying when used through an electronic keyer.
- use directly with any transmitter
- 8 amp. gold diffused silver contacts adjust from 0-.060" & 5-50 grams.
- distinctive blue paddles are of rugged G-10 fiberglass epoxy.
- cabinet is 16 gauge polished chrome steel: 1.95" sq. x 3.75", paddles extend 1.25", weight 10 oz.
- silicone rubber feet for stability.
- 100% US made & guaranteed for 1 yr.

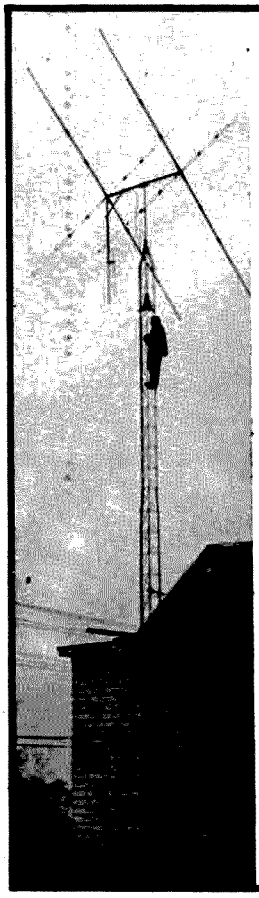
19.95 complete, ppd usa & can. send a check or m.o. sold by mail only

James Research company, dep't: AR-K
20 willits road, glen cove n.y. 11542

Tuning on 15m is the last step and the RL2 relays only are energized with 21.175 MHz rf. Tuning on this band is the same as that on 10m except that the adjustment is made to the C2 capacitor.

The coil tapping point once set for 10m is correct for this band. Front-to-back ratio is about 30 dB.

Antenna Performance



Conservative gain figures for the 3 bands are as follows:

20m – 8 dB
15m – 10 dB
10m – 11.5 dB

The swr will be unity at the resonant point on all bands and will rise up to no higher than 2:1 at the band edges on 20 and 15m. On 10m, an swr of no more than 2:1 was experienced at 28.2 MHz, dropping to unity and then rising to 2:1 at 29.1 MHz. This may appear to be a wide bandwidth for the swr stated, but I feel it attributed to the elements being a full wavelength on 10m.

This antenna has been in use here for 2½ years and the results obtained on all bands are most gratifying when compared to the automatic trapped beams and interlaced cubical quads.

THE BEST
2 METER
CONVERTER

Model 407
$39.95
ppd.

144-146 MHz in, 28-30 MHz out
or 146-148 MHz with a second crystal
Available at $4.95 each.

A full description of this fantastic converter would fill this page, but you can take our word for it (or those of thousands of satisfied users) that it's the best. The reason is simple—we use three RCA dual gate MOSFETs, one bipolar, and 3 diodes in the best circuit ever. Still not convinced?Then send for our free catalog and get the full description, plus photos and even the schematic.
Can't wait?Then send us a postal money order for $39.95 and we'll rush the 407 out to you. NOTE: The Model 407 is also available in any frequency combination up to 450 MHz (some at higher prices) as listed in our catalog.

*New York City and State residents add local sales tax.

73 tests the Grundig **SATELLITE** *Ham Radio Receiver*

...and is impressed!

Those crafty Germans have come up with a remarkable portable receiver, one that seems to have just about everything imaginable. Here is a receiver with separate bandspread dials for each of the amateur radio bands, a receiver that has a product detector so you can copy sideband and CW! It even covers 160m, tuning from 1700–2000 kHz. The 80m bandspread dial covers 3500 to 3800 kHz, with the remainder of the band being adequately covered by the regular shortwave band which covers 1600 to 5000 kHz. The 40m band covers 6900 to 7350 kHz, including CHU, naturally. There is also a 49m band for SWLs, tuning from 5950 to 6250 kHz. The 20m band covers from 13.9 to 14.5 MHz. 15m covers 20.5 to 21.75 MHz. 10m is in two bands, one from 26.9 to 28.4 MHz, which includes the citizens band, and one from 28.3 to 29.8 MHz.

There is also a band for low-frequency listening from 150 to 450 kHz, plus the broadcast band and the FM 88–108 MHz band.

It has so many features that it is hard to list them all. The i-f response can be switched from broad to narrow, giving optimum response for FM music and crowded ham-band reception. The speaker is huge and has a remarkable richness of tone for a portable radio. The receiver operates on built-in batteries or ac, and has a meter to show the battery voltage. The sideband unit has a narrowband filter (to cut down noise pulses) as well as a manual avc function. There are separate tone controls, an S-meter, a 13-section antenna, provisions for using your car antenna, an outside FM antenna, and a shortwave or ham-band antenna. There are inputs and outputs for a tape unit or phonograph player and a plug for external loudspeakers.

When we removed the Grundig from the carton here at 73 to test it just about everyone on the staff blew their minds over it. Everyone had an immediate case of wants. There was a tussle between the rock fans to listen to FM and the hams to listen to 20 meters. The receiver is stable enough to allow excellent sideband reception and there are enough controls to give you good flexibility in tuning in signals. This certainly could be used for communications for it does a lot better job than some ham receivers that are not all that much lower in price. The major advantage of this receiver is that it is portable and that it covers just about anything you would normally want – AM, FM, SSB, or CW. With a little converter it would be excellent for tuning in FM repeaters!

How To Order An Antenna Tower

There are many kinds of towers on the market today. You may choose the kind that requires guying or the type that is self-supporting. You may select a foldover, a crankup, or the kind that hinge at the base and then either fold over or crank up. Then there are the rigid types that rise section by section after the base has been securely planted. Towers are made of steel or aluminum. They can be of telescopic masting or braced triangular or of square-framed design.

Confusing? You can say that again!

So how do you sort out the facts? How do you know what *you* want?

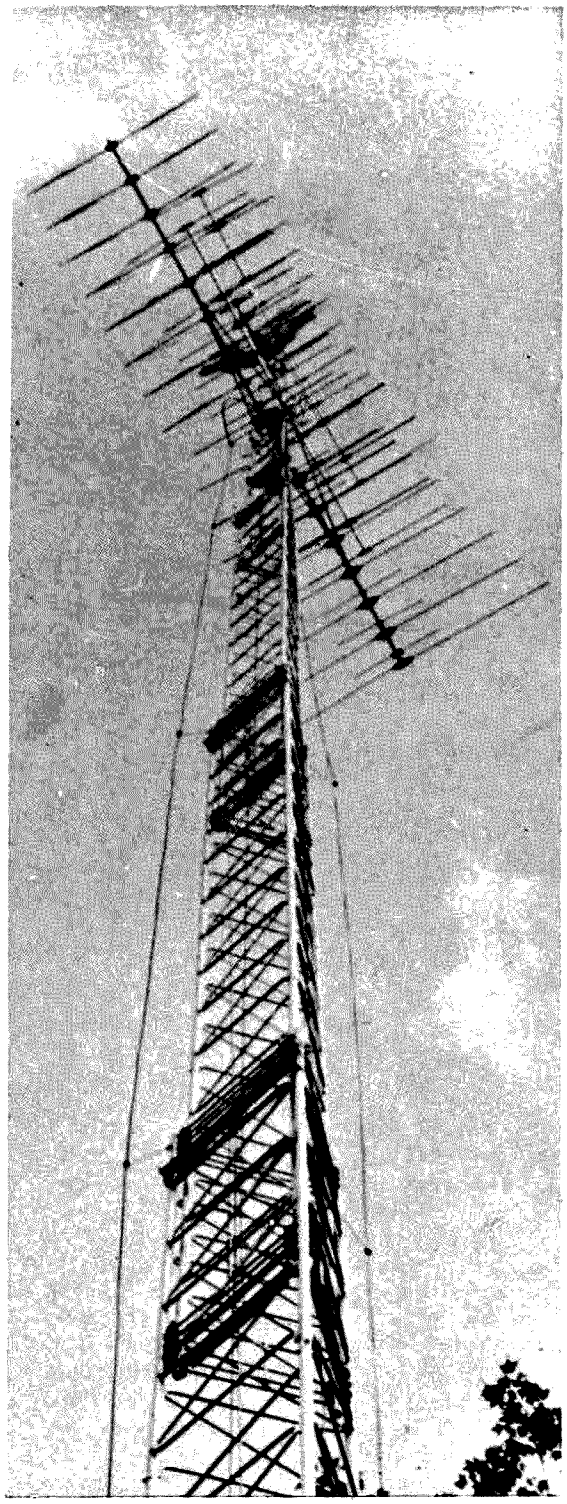
First you must know what you can legally or permissively put up. This depends upon either the landlord or the zoning restrictions in your town. Then there is the esthetic consideration meaning mainly your good wife, and, of course, your neighbors' opinions too. For you to put up a stark ugly structure on the front lawn on a street of fine homes, you had best at least be prepared for some tongue wagging, or worse, a letter from the neighborhood improvement association. But assuming that such considerations as to where this structure will be placed have been settled, then you must decide what the tower will be used for specifically!

The tower selected must reflect the maximum windload in a horizontal direction which is imposed by your antenna, or combination of antennas, assuming a velocity of 80 mph (which is the minimum recommended standard). Depending upon historical weather statistics for your area, you must be conservative in choosing a tower design—a skimpy choice usually results in a total loss within a year or two. Go ahead then in adding up windload. With the small TV or VHF beams, 2—5 sq. ft. of load should be expected. Larger VHF beams in small 10 meter arrays require 5—8 sq. ft; 2 element tri-band quads also fall in this category. Typical tri-band 3 element beams require 8—11 sq. ft. A typical small VHF antenna stacked on top of a 3 element tri-band beam requires a total of 11—14 sq. ft. Two small HF 10 or 15 meter 3 element beams would call for 14—18 sq. ft., while even a single large 20 meter array requires 18—22 sq. ft. Even the light 40 meter beam needs 26 sq. ft. By the way, the sq. ft. of windload times 20 equals the lateral pressure in pounds at 80 mph. At 90 mph you multiply by 25, at 100 mph you multiply by 30, at 115 mph—40, at 130 mph, factor is 50, and at 160 mph you will use a multiplier factor of 60. And when you do all these calculations be conservative. In still another direction, that of your future ham operations, allow for the fact that you may want to expand your activities and thus your antennas.

Bear in mind that the height of your antenna and the top of your tower must be at least 5—10 ft higher than the average foliage in your backyard, and preferably should be halfwave or higher for the lowest frequency that you are going to operate on. In general, quads will provide satisfactory operation in lower heights than yagis.

Secondly, your bankbook must be consulted. While it is true that a ham's station performance is more directly related to good antenna performance, it is also true that your first obligation must be to the family and their needs. Some idea of cost can be gleaned from the following:

- Minimum cost of steel in 10 ft sections with guys, rotor plate, masting, anchors, etc. will be about $2.50 per lineal ft of erected height.
- Minimum cost of aluminum – 8 ft sections with rotor plate and masting (no guys) will approximate $3.20 per lineal ft of erected height.
- The minimum cost of a crankup or foldover design in a guyed steel tower will be about $5 per lineal ft of erected height.
- Minimum cost of self-supporting crankup or foldover steel tower will be $8 on the same basis per ft.
- Minimum cpst for a hinged base, aluminum construction, crankup or foldover self-supporting type will be $9 per ft of erected height.



By referring to the above and knowing how high you wish your antennas to be, you can quickly compute minimum values for basic types of tower design. But please remember, these are minimum values, and our nation is in a depression/recession, with inflated or deflated prices, and we surely know prices go up, not down!

Remember, too, that there are other considerations. You wouldn't put a guyed tower in your backyard where your kids were playing ball. First thing you would hear would be a hysterical wife on the telephone. Then, too, how frequently are you apt to move? How easy is the tower to erect? Do you need two or three cases of suds and the whole club for a rooting section?

Maintainence is annoying, especially antenna repairs after a winter storm and you're 55 years old with four extra inches of spare tire to hinder your climbing. Another consideration is whether or not you have provided for the possibility that for some reason your tower and antenna may come crashing down on the neighbors home next door. Because of all these things and many others that you can think of to fit your individual circumstance, towers do take a lot of study

We sell them all, and literally have dozens in stock, but over many years of selling ham gear, we have reached the conclusion that one brand is especially appealing to the ham. I now refer to HEIGHTS Aluminum Towers, appealing because their design provides a great flexibility for your particular needs with respect to strength and height. Further, should your circumstances change, their design best lends itself to easy dismantling and reerection – to expansion – to freedom from the maintainence problems.

Detailed literature is available for the asking on any tower. Furthermore we'd be glad to quote on a package deal for any rotor, antenna, or tower combination or to render advice on your problem. We have helped others, maybe we can help you.

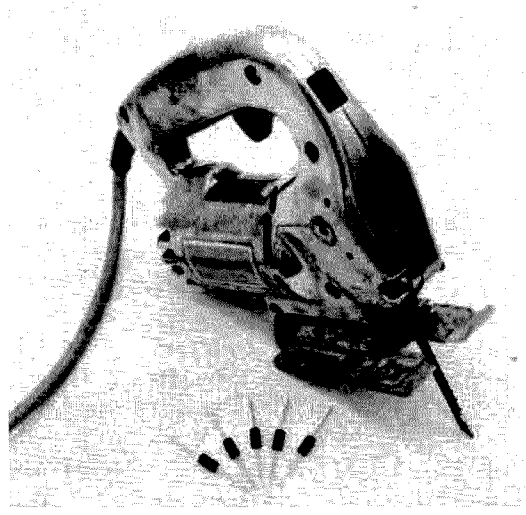
NEW PRODUCTS

In-Circuit Resistance Checker

The model FE20 "Hi-Lo multimeter checks conductivity of transistors, diodes, and rectifiers; with a flip of the function switch the ohms section is powered with a lower voltage (below the conductivity point of solid-state devices). Resistances can then be measured in-circuit for true values without solid state device conducting and causing erroneous results. Both Hi and Lo



ohms are read on the same scale to avoid confusion. Other features include a tenth of a volt full scale for more accurate measurements of transistor biases. A high voltage probe is also shipped with each multimeter to extend the voltage range to 30,000 volts. A low voltage probe with isolation resistor is also provided. The new meter has 9 dc ranges, 3 high voltage ranges, 9 ac ranges, and 7 resistance ranges. The FE20 is priced at $129.50. *Sencore, Inc., Addison IL 60101.*

Semiconductor Data Book

The Motorola Semiconductor Data Book (Fourth Edition) is the largest yet – 2160 pages – and includes specifications for all discrete semiconductors registered by the EIA at publication time. The book also features a new arrangement of data that makes it easier than ever to find information on semiconductors; other sections of the book include case outlines for semiconductors, selector guides to digital and linear integrated circuits, and application notes that explain how to use the transistors, diodes, and other devices described in the Data Book. *Motorola Semiconductor Products Inc., Box 20912, Phoenix AZ 85036.*

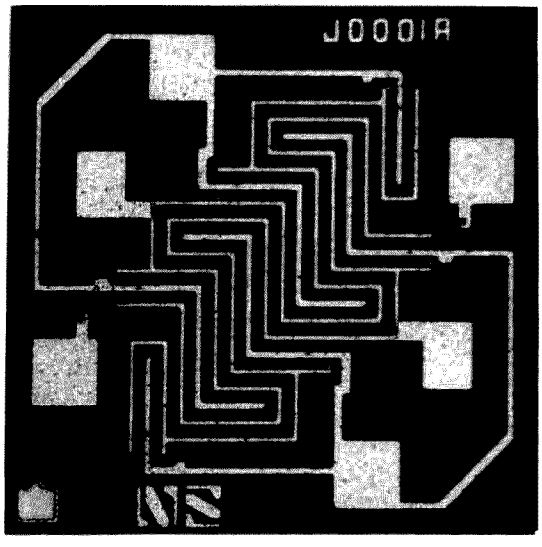
3 Amp Epoxy Rectifiers

The ER2000–ER2006 series of plastic incapsulated, low cost, hi rel 3 amp rectifiers offers design engineers increased packaged density excellent hermeticity, low power dissipation and

high surge limit in high temperature applications. Voltage range is 50 to 1000V with mass surge limit of 200 amps. Average forward current is 3 amps. *Transitron Electronic Corp., 168 Albion St., Wakefield MA 01880.*

3 kW Vacuum Coaxial Relay

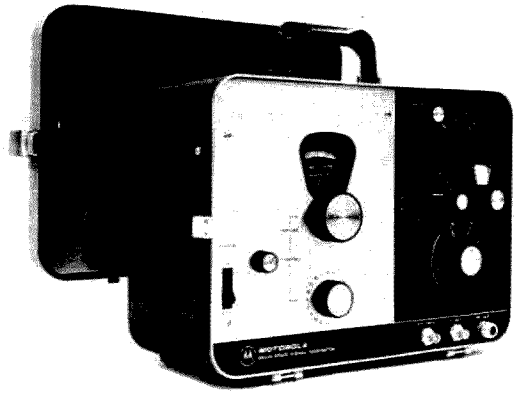
A vacuum coaxial crossover/transfer relay utilizing both a vacuum dielectric and the latest in coaxial switch technology is now available. The Series 313 will handle up to 3 kW of power at 30 MHz. It utilizes switch contacts enclosed in a vacuum dielectric in a copper and ceramic



envelope to ensure permanently low and stable contact resistance, long life, low loss and inherently low noise level with no distortion. The Series 313 is supplied in a variety of alternate versions with various electrical and mechanical

characteristics. *Dow-Key Company, 2260 Industrial Way, Broomfield CO 80020.*

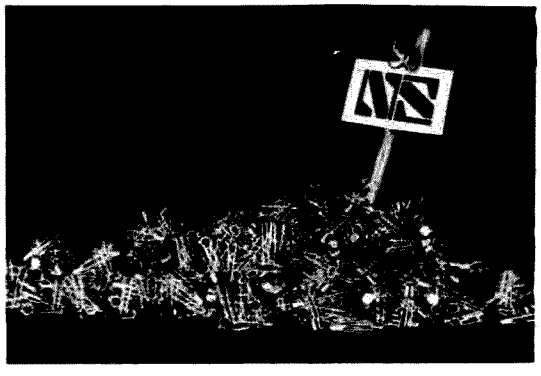
Monolithic, N-Channel, Dual FETs



The FM3954 series are monolithic dual JFETs manufactured with special processing and a radical new departure in geometry. The geometries of both FETs are intertwined to obtain a perfect match. The series completely removes the prob-

lem of complicated testing because each dual die is a perfect match. Features of the series include very close tracking regardless of bias point, from 50 μA to 500 μA, low leakage of 100 pA and high gain of 1000 μmhos. *National Semiconductor Corp., 2975 San Ysidro Way, Santa Clara CA 95051.*

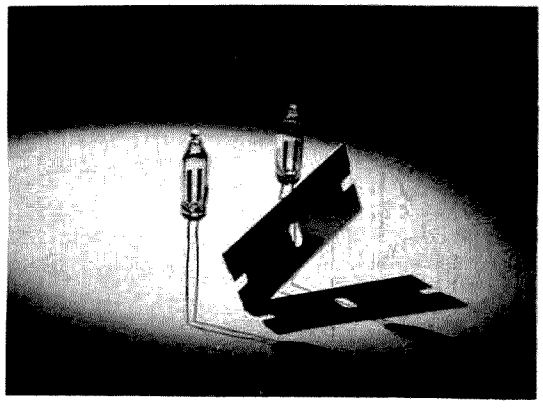
Solid State FM Signal Generator



Electronic vernier tuning provides a more precise setting of frequency with or without

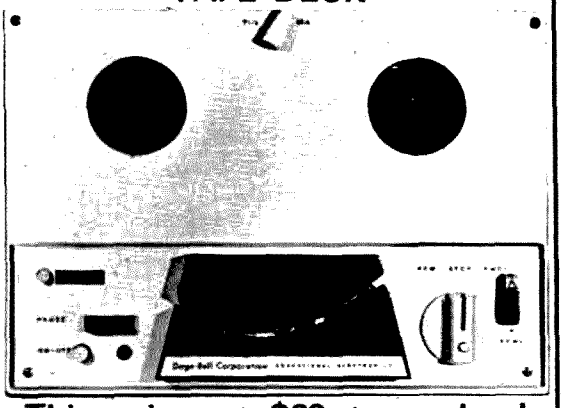
modulation for the solid state nuvistor oscillator, FM signal generator. Incremental electronic tuning allows the frequency to be adjusted 16 kHz either side of zero center. The unit's automatic level set now sets a "red line" reference automatically. External modulation and deviation sensitivity of only one volt input provides a full 16 kHz deviation eliminating the need for high powered external signal sources. *Precision Instruments Department, Motorola Communications & Electronics, Inc., 1875 Greenleaf Ave., Elk Grove Village IL 60007.*

Low Cost General Purpose FET Amplifiers



This group of low cost general purpose FET amplifiers offers outstanding performance in all types of amplifier applications due to their low noise (2.5 dB max), low leakage (100 pA max)

and low capacitance (2.0 pF max). They also offer low on-resistance. *National Semiconductor Corp., 2975 San Ysidro Way, Santa Clara CA 95051.*



Neon Tube Repeatability In Timing Circuits

The close tolerance in breakdown voltage characteristic and the high leakage resistance of the A039A neon tube provides a high degree of repeatability when it is used in RC timing circuits. Breakdown voltage of the tube is 66–72 volts in the dark. Maintaining voltage is 50–60 volts at .3 mA. Leakage resistance of the A039A

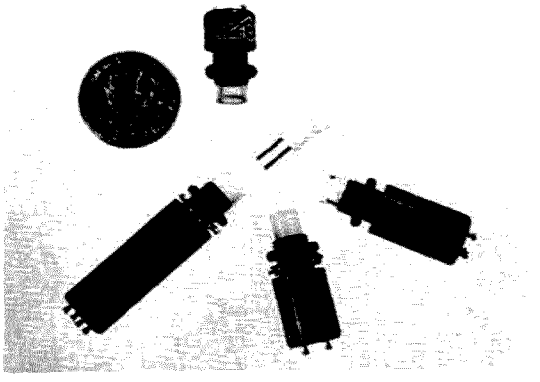
is greater than 20,000 megohms. The A039A is 27/32" in length and .244" diameter. It is provided with 1" tinned leads. Where electrical characteristics are slightly different the A243 neon tube has a breakdown voltage rating of 68–76 volts and a leakage resistance of 10,000 megohms minimum. *Signalite Inc., 1933 Heck Ave., Neptune NJ 07753.*

TAPE DECK

This unit cost $69 to produce! We now offer a limited quantity of these new original packed tested units for only $29.95 plus shipping and handling.

On cash with order, shipment is made the same day of receipt of order for only $4.55 shipped P.P. Ins. anywhere in the USA. COD orders accepted, same prices plus COD fee.

LOOK AT THESE UNPARALLELED FEATURES NOT FOUND ON ANY OTHER DECK OF U.S. MANUFACTURE AT MUCH HIGHER PRICES.



STOP–START: Full speed attained in less than 0.5 sec.
DRIVE CONTROL: Single rotary control for all functions. Interlock prevents tape breakage, stretching and spilling when changing mode of operation.
MOTOR: 4 pole shaded, 50/60 Hz.
BRAKES: Mechanical braking eliminates need for adjustments.
TAPE SPEEDS: 3¾ and 7½ ips.
WOW AND FLUTTER: Less than; .25% at 7.5 ips; .3% at 3.75 ips.
POWER: 26 WATTS', 120V 60 Hz.
DIMENSIONS AND WEIGHT: 10 5/16" x 14¼" x 5½" Below panel, 1½" above panel. 14 pounds.
REEL AND TAPE SIZE: 7" max. reel, ¼" tape.
HEADS: Record/playback staggered two track sterio, dual erase. (¼ track stereo erase, and R/P head available, $9.95 for complete kit).
COUNTER: Resettable 4 digit index counter.
R/P FREQUENCY RESPONSE: 40 to 15,000 cps ± 3 dB.

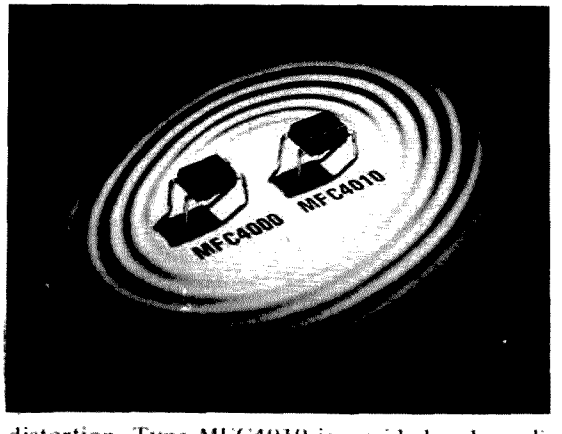
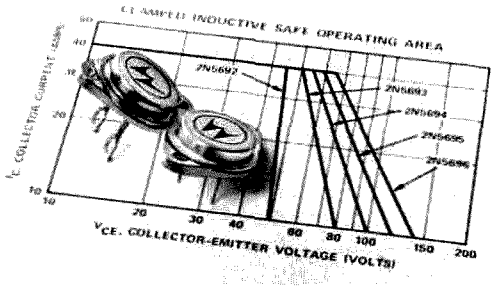
Subminiature LED Indicator Line



LEDs (light emitting diodes) are used as the light source for subminiature indicators and switch indicator devices. The "SS" series are resistant to shock, vibration and other environmental extremes. The body diameter is .360" and

3/8" mounting centers in a ¼" panel hole. Units mount from the rear and are secured by lockwasher and knurled nut. Turret lug terminals are provided. *TEC, Inc., 6700 South Washington Ave., Eden Prairie MN 55343.*

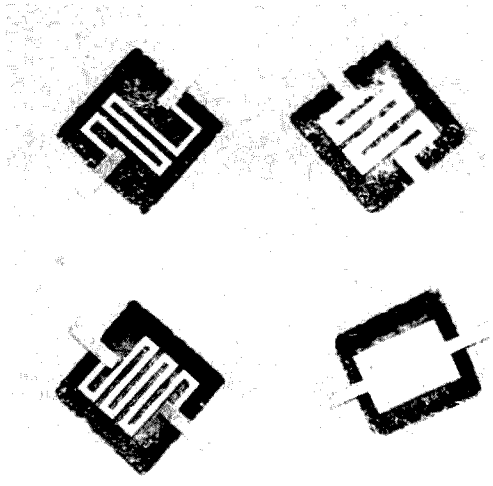
Inexpensive Integrated Circuits



Two devices, Types *MFC4000* and *MFC4010*, are the first units in a line of inexpensive consumer integrated circuits. Type MFC4000 is a low-power audio amplifier featuring 250 mW of audio output power and low total harmonic

distortion. Type MFC4010 is a wide-band amplifier featuring high gain and low typical output noise. Both devices are housed in a four-lead plastic package. *Motorola Semiconductor Products Inc., P.O. Box 20912, Phoenix AZ 85036.*

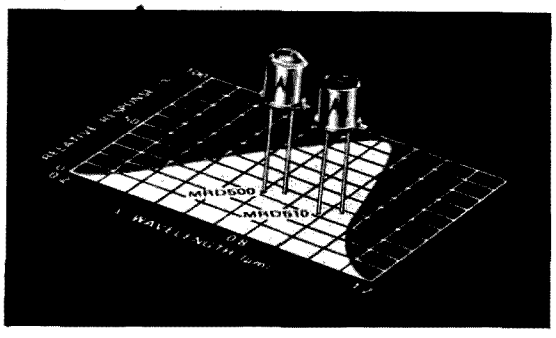
Germanium Power Transistors



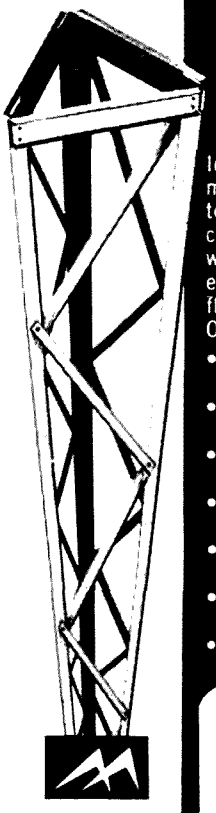
Types *2N5692 through 2N5696*, 40-ampere pnp germanium power transistors feature significantly improved safe operating area. Minimum collector-emitter sustaining voltages range from 50 to 140V at 10A, and from 45 to 65V at 40A. The series is ideal for use in voltage/current

regulators, motor controls, inverters, converters, and servoamplifiers. *Motorola Semiconductor Products Inc., Box 20912, Phoenix AZ 85036.*

Chip Resistors Feature Beam Leads



A series of unencapsulated resistors featuring small size (50 mil square) and gold beam leads, with resistance values ranging from 5 to 5000Ω, is offered by Motorola. The miniature resistors



feature a temperature coefficient of 50 ppm/°C and maximum power dissipation of 125 mW. *Motorola Semiconductor Products Inc., P.O. Box 20912, Phoenix AZ 85036.*

Fast Photodiode has High Radiation Sensitivity & Low Dark Current

Featuring ultrafast response, high radiation sensitivity, low dark-current level, and low cost are two p-i-n photodiodes, *MRD500* and *MRD510*. Both devices are sensitive over a

AL SERIES ALUMINUM TOWERS for uhf - vhf

Ideal for mounting industrial, commercial, citizens band, amateur, or television receiving antennas. Exceptional strength in proportion to weight qualities. Easy access to equipment mounted on the Microflect top mast extension.
Other features are:

- 10 to 120 feet high in easy to erect 10 foot sections.
- Available factory assembled or in kit form.
- Lightweight all aluminum 10 foot sections weigh only 12½ lbs.
- Low maintenance, will never rust or require painting.
- Staggered ladder treads for easy climbing.
- Can be used for direct radiator at HF.
- Wide variety of mounting brackets and accessories available

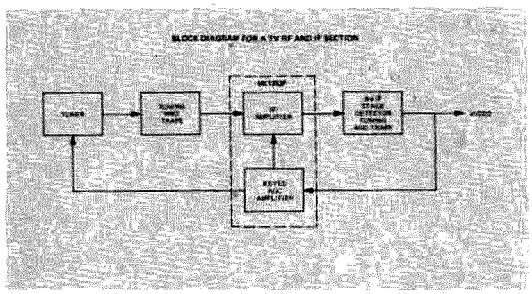
wavelength of 0.4 to 1.1μ, with peak sensitivity at 0.8μ. They also have a low series resistance of 10Ω max and a maximum total capacitance of 4 pF. *Technical Information Center, Motorola Semiconductor Products Inc., Box 20924, Phoenix AZ 85036.*

Data Selector Highlights High Speed



The dual four-channel data selector, Type *MC4000*, features high speed characterized by a typical propagation delay of 11 ns from data input to output. The selector consists of inter-

nally connected low-level inverters and high-level *and*—*or* gates. Data on any one of the four inputs is selected according to the binary code on the control lines and is routed to the output. *Motorola Semiconductor Products Inc., P.O. Box 20912, Phoenix AZ 85036.*

TV Video I-F Amplifier

Type *MC1352* TV video i-f amplifier has an integral keyed agc amplifier circuit in addition to the i-f amplifier circuit of the Type MC1350

device. It constitutes a complex TV i-f strip, resulting in cost reduction compared with discrete circuits. *Motorola Semiconductor Products Inc., P.O. Box 20912, Phoenix AZ 85036.*

De-RF Your VTVM

A partial schematic for a common vtvm is shown in Fig. 1. The modifications shown in the bold lines of the schematic allow the vtvm to be used near a strong rf field and can be added to almost any vtvm without affecting the accuracy of the meter.

This modification bypasses the rf to the bridge tube (12AU7), keeping the rf from driving this tube into grid rectification.

The capacitors used can be anything from .001 to .01 disc ceramic. They should

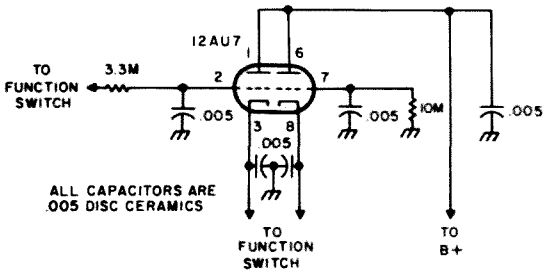


Fig. 1. A partial schematic for a common VTVM.

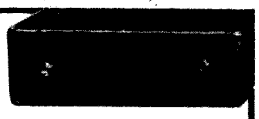

be mounted with short leads and returned to the same ground point. The capacitors which are already in the circuit need not be bypassed.

This modification was added to the Heathkit Model V5A vtvm and it is no longer affected by rf.

These modifications *do not* apply to an ac meter.

Getting Your Extra Class License

STAFF

Part XVII: Conclusion

All things end, the philosophers tell us, and this installment brings our study course for the Extra Class exam to its close. All we have left from the 90 questions on the official FCC study list are a half-dozen "miscellaneous" items covering a number of relatively minor but nevertheless important points.

The official questions which remain for us to examine are:

47. What useful functions does a balanced modulator perform in a radio transmitter?

69. What is a third party agreement? What countries have agreements with the United States?

83. Describe briefly how an ac power supply produces a dc output voltage. Discuss the merits of using choke-input versus capacitor-input filters in power supplies. How does the leakage resistance of the capacitors affect the output voltage? Also, what is voltage regulation as related to power supplies?

85. What is push-pull amplifier operation?

86. What is a Q-multiplier and how is it used in amateur equipment?

89. What visual observation within an operating vacuum tube's envelope would indicate that the tube is gaseous?

90. Be familiar with Part 97 of the Commission's rules.

Since these questions cover such a broad range of subject matter, we'll abandon our usual technique of rephrasing the FCC questions this time, and simply extend our looks a bit past the specific points asked. Keep in mind that the actual Extra Class exam may contain questions of similar nature on other parts of radio theory—but the official study questions are intended to provide adequate preparation for the "real thing" and any questions in radically different areas will probably be few and far between. All set?

What Does A Balanced Modulator Do?

The balanced modulator is generally considered to be a part of SSB or DSB equipment, although it doesn't necessarily have to be. The function of a balanced modulator is to mix (or heterodyne) two input signals into a group of output signals; so far, that's the same as the function of any other kind of modulator or even a receiver mixer stage.

But the balanced modulator differs from a conventional modulator in one essential particular. Where a conventional modulator or mixer produces *four* signals in its output—

the original "carrier," the modulating signal, and the sum and difference of these two inputs (generally called the upper and the lower sideband)—the balanced modulator has only three parts to its output. The "carrier" is suppressed by being "balanced" out, and the output contains only the modulating signal and the two sidebands.

In a radio transmitter, the modulating signal is usually at audio frequency while the carrier and the sidebands are at rf. The af is not coupled out from the mixer stage, so that a conventional modulator's output (after the coupling) contains only the carrier and the two sidebands.

A balanced modulator's modulating-signal output is similarly disposed of in the output coupling circuit, and the carrier signal is balanced out in the modulator circuit, so that the effective output of a balanced modulator in a radio transmitter consists of *only* the two sidebands. In a phrase, the balanced modulator produces a DSB signal.

Because the carrier disposal is accomplished by built-in circuit action, rather than by filters, a high degree of carrier suppression can be achieved. It's limited primarily by the care taken in adjusting the circuit, and by the shielding which prevents stray carrier-frequency signal from leaking around the circuit; the balanced modulator stage itself is capable of "perfect" rejection of the carrier in theory at least, and in practice 30 to 40 dB of suppression is normal.

For this reason, almost all SSB transmitters use some balanced modulator circuit to generate the original SSB signal. "Phasing" designs use a pair of balanced modulators, in which the phase relationships between carrier and modulating signal differ, so that the individual outputs of the two balanced modulators will add together for one sideband and cancel out for the other. "Filter" designs depend upon filter selectivity to reject the unwanted sideband, but the balanced modulator's rejection of the carrier together with frequency shaping in the audio channel before modulation provides a region near the carrier in which little or no signal is present, and thus eases the task of the filter designer.

The balanced modulator has another feature which comes along automatically at no extra charge. Since carrier suppression depends upon the fact that the modulator *is* balanced, all that's necessary to put some carrier in is to deliberately unbalance the modulator. This permits carrier insertion, which is sometimes handy to have.

Balanced modulators aren't restricted to SSB and DSB transmitters, either. The Armstrong technique for producing FM (it actually produces a mixture of phase and frequency modulation, but it's the system normally used by FM broadcasting stations) also makes use of balanced modulators. If the carrier is removed from an AM signal, shifted in phase by exactly 90 degrees, and then reinserted into the signal, the result is PM. If audio frequency response is properly shaped, the PM which results cannot be distinguished from FM by any method. The Armstrong technique uses a balanced modulator to simultaneously produce the AM signal and remove its carrier, and a separate phase-shift network to shift carrier phase by the necessary 90 degrees. The carrier is then reinserted, and the result is FM—but crystal-controlled. This technique is seldom used by hams because we have no need for a wide frequency swing in our FM signals, but it's the mainstay of commercial FM broadcasting.

A number of balanced-modulator circuits exist. They range from simple diode-ring switches, in which the carrier signal acts as a switch to steer the modulating signal through coupling networks (or vice versa, with the modulating signal switching the carrier), up to push-push amplifiers. A typical amplifying balanced modulator using tetrode tubes is shown in Fig. 1. In this circuit, the carrier is applied to both control grids in push-pull while the output is taken from both plates in parallel. With no modulating signal present, any increase in current through one tube (caused by the carrier waveform's going positive) is balanced out by a corresponding decrease in current through the other tube, because the waveform at its control grid goes negative by the same degree. Therefore the carrier is balanced out of the output circuit, and nothing emerges from the plate tank.

When a modulating signal is applied to the screen grids in push-pull, though, the

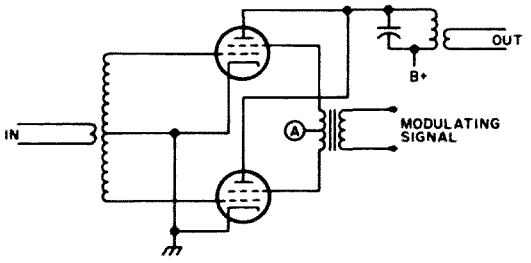

Fig. 1. This oversimplified schematic of a tetrode balanced modulator is intended to show only the operating principle. All arrangements for tuning the grid circuit, supplying grid bias, and bypassing the screens have been omitted. Carrier input applied to the terminals labeled "IN" goes to the two control grids in push-pull, and balances itself out so that none emerges in the parallel-connected plate circuit. When modulating signal is applied to the screens, also in push-pull, the circuit's balance is upset and sidebands are not canceled out. Point "A" may be returned to ground, to a slightly negative voltage, or to a slightly positive voltage, depending upon the tubes used. It should not connect to a normal screen-voltage level, since full screen voltage in this circuit would cause excessive power dissipation in the tubes.

two tubes no longer operate under identical conditions if any modulating signal is present. If a modulating signal drives one screen slightly more positive, it will at the same time drive the other screen slightly more negative. The carrier signal is no longer balanced out as a result. When the tube with the positive screen gets positive control grid voltage as well, it draws correspondingly more current than the other tube; the net change at the plate tank circuit is a slight increase in current.

As both modulating and carrier signals vary in polarity and strength, the power in the plate tank circuit will vary. The net result is that no power gets out at carrier frequency, but the signal components at both the sum and the difference frequencies (or in the upper and the lower sidebands) do appear and can be coupled out.

This circuit was popular as an "instant" DSB transmitter when double sideband was first pushed some 10 years ago; it still has its uses.

A similar circuit using only one tube, called a "beam deflection tube," has been used as a receiver mixer and as a product detector, as well as for color demodulation in TV receivers. The stereo multiplex circuits in quality FM receivers also make use of balanced modulators to recover the stereo signal and route it to the appropriate channel. But these uses are outside the range of the FCC question, which deals only with "useful functions" in a radio transmitter.

What Are Third Parties? The phrase "third-party traffic" is frequently encountered both on the air and in the ham literature, not to mention its occurrences in the FCC rules and international regulations. What is it all about?

The "third party" does not refer to political innovations. It's a legal phrase similar to "the party of the first part" and "the party of the second part," and it has a most specific meaning in regard to ham radio.

In any QSO, only two parties are involved; they are the ham who is talking (or transmitting), and the one who is listening (or receiving). A "third party" is anyone else other than one of these two.

It might appear that a roundtable or net operation would have more than two parties, but in any properly operating net or roundtable only one person transmits at any given time. He is the first party, and all the other participants (collectively) are the second party. Again, a "third party" is anybody on the outside.

The international rules governing radio communication include a specific prohibition forbidding amateur stations from handling any kind of traffic or messages on behalf of "third parties." This means that, so far as this rule is concerned, you can't tell the guy on the other end to give your regards to his family—for his family is a third party to the conversation. You might argue that the message is on your behalf, not theirs—and you *might* get by with this argument. But you certainly would not be safe in sending *your* family's regards to *his* family.

This rule came into being because, in most countries, the radio communications facilities are government-owned, and the governments which created the rules feared that ham stations might compete with the government monopolies on traffic handling. In this country, of course, the commercial radio communications services are privately

owned rather than being parts of the government, and so this nation has not been an enthusiastic supporter of the "no ham traffic" movement.

In fact, that same rule which generally forbids third-party messages through ham stations includes a loophole, to the effect that the rule may be suspended by mutual agreement between two nations, so far as the hams of those nations are concerned. This part of the rule was written to satisfy U.S. requests, in part at least.

A "third-party agreement" is such an agreement between two nations that their hams may handle third-party traffic. This country has third-party agreements with about 30 other nations, and message traffic can be handled to and from those countries. Messages within this country can, of course, be handled without third-party restriction because this government has chosen to permit them. The exact list of nations with which third-party traffic may be handled varies from time to time, as new names are added (and occasionally, old ones taken off when agreements are canceled for one reason or another). Check a current list just before going for the exam to be sure.

Power Supplies. Every item of electronic equipment requires a power supply of some sort. The pocket transistor receiver is probably the simplest in this respect, because its power supply consists of a single dry-cell battery (usually the 9V size). Most of our ham equipment, however, is not so simple nor so portable. Producing 1 kW of dc input to a transmitter requires several kilowatts of power, and the supply which does this job is a bit bulky.

Power supplies in general can be grouped into three main classes. The first, typified by the transistor set, gets power directly from expendable batteries. It's dc to begin with, and it's also at the proper voltage. This type of power supply is simply one or more batteries, and we can ignore it from here on.

The second class also operates from a battery, but gets all its various output voltages from a single rechargeable battery which is normally of comparatively low voltage. The mobile rig's vibrator or transistorized supply is an example of this type. It's fairly complex, but once the low-voltage dc from the battery is changed to either ac or a pulsating dc (either of which will go through a transformer nicely), it becomes much the same as the third class.

The third type, which we'll examine in some detail here, operates from ac input. The normal ac input voltage is either 117V from a wall plug, or 220V from a 3-wire connection. The output voltages may range from a few volts (to replace the battery in a transistor set) up to several thousand volts. The ultimate output is dc, but its "purity" may range from being almost completely free of hum, ripple, and noise, just like a good battery, to being almost ac and qualifying for the "dc" label only because current flow never reverses.

The ac power supply consists of three major sections: the transformer (which changes the input voltage to the appropriate voltages for the desired outputs), the rectifiers (which convert the ac to pulsating dc), and the filter (which removes the pulsations from the dc and smooths it into something approximating "pure dc").

The transformer in the power supply establishes the maximum output voltage and current available. While it's possible to cut down the output voltage by resistors, it's wasteful of power and components to do so, and as a result the transformer is normally chosen to produce the proper output voltage rather than merely letting it set the maximum. The relationship between rms ac voltage at the transformer secondary, and dc output voltage, depends on both the rectifiers employed and the type of filter circuits used. In general, the dc output will almost never (with conventional rectifier circuits) be more than 1.5 times the rms ac voltage at the secondary, and will seldom be less than the rms ac value.

The ac from the transformer secondary is applied to the rectifier circuit. Most transformer-type supplies use full-wave rectification; most of these, in turn, use the center-tap circuit which requires two rectifiers. Each rectifier anode connects to one end of the transformer secondary. The center-tap of the secondary is the negative terminal for the dc output, and the cathodes of the rectifiers (which are connected together) provide the positive terminal.

Some full-wave rectifier circuits use the bridge circuit, which takes four rectifiers but needs no center-tap on the transformer secondary. If a bridge circuit is used with a transformer which was designed and rated for center-tap circuits, the secondary voltage to figure on is that from end to end of the winding, rather than from one end to center tap. This means that a secondary rated (as so many TV transformers are) at 350-0-350V would give 700V end-to-end, and with a bridge circuit could be expected to produce a dc output voltage around 900 to 1100 volts.

Sometimes a half-wave rectifier circuit is used. This takes only one rectifier, but is neither as efficient in its use of the ac nor as desirable in terms of simplicity of filtering as a full-wave circuit. The half-wave circuit simply blocks off half of the ac waveform and lets the other half pass through; the result is dc output which pulsates at input ac frequency. All it really is is a string of half-cycles of the input ac. A full-wave circuit, whether center-tap or bridge, passes both halves of the ac waveform, but steers them around so that they emerge always going in the same direction. This produces twice as much power with less strain on the rectifiers, and also makes the ripple frequency be twice the input frequency—which means it's easier to get rid of the ripple.

The filter circuits make use of capacitors to store the pulsating dc and smooth out the ripple. Sometimes, the capacitors are the only elements in a filter, but by themselves capacitors don't do much filtering. If inductors or resistors are placed in series with the load while capacitors are in parallel with it, the inductors will oppose any changes in current while the capacitors tend to smooth things out, and almost pure dc can be obtained.

The two most commonly used filter circuits are shown in Fig. 2. The only difference is that in one, the input element is a capacitor, and in the other, an inductor or choke.

This single difference provides the names for the circuits: "capacitor input" and "choke input." While the circuits are extremely close to each other in appearance, they have some notable differences.

A capacitor, when discharged, is almost a short circuit even to dc. It's only after the capacitor reaches nearly full charge that the current flow into it comes down to small levels. A capacitor-input filter, then, represents almost a dead short to the transformer and rectifiers when power is first turned on. The larger the capacitor, the worse the short—yet it takes a large capacitor to do much smoothing. One of the major characteristics of a capacitor-input filter is the enormous power surge into the input capacitor when power is applied the first time.

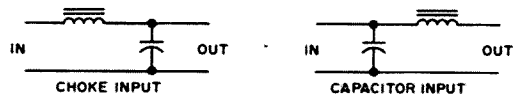

Fig. 2. The two basic types of filter sections used in power supplies are shown here. Note that both are lowpass filters, and could be designed by normal lowpass techniques if one deisred. However, the frequency-cutoff requirements in a power supply filter are most uncritical, and so the complexity of audio filter design is unnecessary. The only requirements are that the choke's inductance, and the capacitor's capacitance, both be large enough to reduce ripple to acceptable terms A single section of filtering usually reduces ripple by about 95%; two sections will reduce ripple by 0.95 times 0.95, or 99.75%. More than two sections are seldom used.

As power is taken from the supply, it tends to discharge the filter capacitors, and so with each cycle of rectified ac there's still quite a charging-current flow into the capacitor. A capacitor input filter will, then, draw more current from the transformer (for a given dc load) than would some other type.

This is generally considered to be a disadvantage, but it has a compensating advantage. Under light current load, the input capacitor will charge up to nearly the peak voltage of the rectified ac, which is 1.4 times the rms voltage. With light current loads, the voltage will remain near this peak. Thus a capacitor input filter produces a higher output voltage—provided that load current is low. As load current increases, the capacitor voltage drops, and the advantage is lost.

A choke opposes any change in current flow, and so the choke-input filter tends to retard the high current flow into the filter

capacitor. This reduction of charging-current surges means that less current is taken from the transformer to keep the capacitor charged, and so more is available to the load. For the same transformer, a choke-input filter can deliver more current.

Offsetting this advantage, in some applications, is the fact that the choke (by slowing down the charging) prevents the capacitor from ever charging up to the peak voltage value if any load current is coming out. Thus a choke-input filter delivers more current, but at lower voltage.

Complicating the action of the choke-input filter is the fact that a certain minimum current *must* be drawn through the filter to make the choke behave as intended. The bleeder resistor value is chosen so that this minimum load is always taken; this power is "wasted" insofar as producing any useful work is concerned.

Most power supplies use at least two filter capacitors separated by a series choke. If choke input is employed, two chokes are used. Because of the additional reactance of the second choke, ripple is usually lower from the choke-input design; if a corresponding reactance were added to the capacitor-input filter, its ripple would be reduced equally.

The output element of all filters is a capacitor. It performs little filtering action in most cases; its purpose is to serve as a storage reservoir to satisfy sudden surges of load current and keep output voltage from falling when this happens. That is, it helps determine the "voltage regulation" of the supply. The larger the value of output capacitor, the better the regulation, in general.

"Voltage regulation" in a power supply is the change in output voltage with changes in load. Any supply will produce higher output voltage when it is unloaded than it will under heavy load. The change in voltage from maximum to minimum is called the "regulation" of the supply and is often expressed as a percentage. Just what this percentage refers to differs from one engineer to the next. Some obtain the percentage by taking the *change* in voltage as a fraction of the minimum voltage, some get it by taking the change as a fraction of the maximum voltage, and some get it by taking the ratio of minimum to maximum.

This can lead to most conflicting descriptions of the same power supply. Let's assume we have a supply which produces 200V without load, and under maximum load the output drops to 150V. This is pretty poor regulation by anybody's standards, but let's see how the three ways of figuring it would differ. The first method would take the change, 50V, as a fraction of minimum, or 150V, and report a regulation of 33-1/3%. The second method would take 50 as a fraction of maximum, 200V, and report 25%. The final way would take the ratio of minimum to maximum, 150/200, and come up with 75%.

If minimum output was 20V (yes, that is an extreme case), the first way would call the regulation 180/20V or 900%, the second way would call it 180/200 or 90%, and the third way would call it 20/200 or 10%. You can see that the phrase "voltage regulation" expressed as a percentage means very little, unless the quantities composing the percentage are specified. The second method is the one most widely used, but the first and third are encountered frequently enough to make one treat them all with caution.

Since capacitors are a vital part of all power-supply filters, and all capacitors have leakage resistance, it's important to know what effects this leakage resistance may have upon the operation of the filter.

If the leakage resistance is high, there is almost no detectable effect. However, many power-supply filters use electrolytic capacitors, which tend to have much lower values of leakage resistance than do paper or oil types.

If leakage resistance is low, it will produce extra load on the power supply, drawing additional current through the transformer and the rectifiers. This added load will tend to reduce the output voltage, and may cause overheating of all power-supply components. In addition to these effects, the leakage resistance acts as a shunt across the capacitor, thus reducing the effective value of its capacitance and making its filtering action less effective. You might say that an extremely leaky filter capacitor is something

like a sieve; neither of them are very useful as storage devices.

The leakage resistance of electrolytic capacitors varies with the capacitor's age. As an electrolytic ages, its leakage resistance usually goes down, making it less useful.

Fortunately (in a roundabout way), the effects of excessive leakage tend to be self-destructive. As abnormal leakage currents overheat the capacitor, it becomes even more leaky. Finally, the point is reached at which the capacitor literally explodes from internal heat. This removes the capacitor from the circuit, and in most power-supply designs nothing else in the supply is damaged (although the inside of the chassis becomes somewhat messy). The violent action *is* desirable, since it prevents the capacitor's turning into a dead short which might destroy transformer and rectifiers as well, and it leaves no doubt as to the identity of the failed component.

What Is Push-Pull Amplifier Operation?

A push-pull amplifier is actually two amplifiers working together, with input and output signals arranged so that plate (or collector) current in one of the two increases at the same time that of the other decreases. In industrial electronics, this same circuit is often called a "differential amplifier" or "diffamp" for short.

The input and output arrangements which are the heart of push-pull operation involve driving half of the stage with a signal which is exactly 180 degrees out of phase with the signal applied to the other half, and reversing the phase of one of the output signals by 180 degrees before combining them.

The most conventional method of obtaining the out-of-phase input signals, and of reversing phase of one output signal with respect to the other, is by using center-tapped transformers at input and output. The phase reversal is inherent when the signals are taken from opposite ends of a single center-tapped winding, with the center-tap used as a common reference point.

Transformer coupling is actually not necessary for push-pull circuits to operate. Especially in audio frequency amplifiers,

don't miss this!!

Fibre optic lens from formally SECRET Starlight Scope.

where a wide frequency response may be needed, a special "phase inverter" circuit may be used to generate two signals of equal amplitude but opposite phase. These signals may then be fed individually to the two halves of a push-pull amplifier, and the two outputs from that push-pull stage used to drive another push-pull stage. The cascading of push-pull stages may continue indefinitely. At the output, another phase-inverter circuit could restore the signals from each half to the same phase. In practice, however, a transformer is usually used at the output if vacuum tubes are being used, because phase inverters capable of handling appreciable power levels with vacuum tubes are not common.

Push-pull transistor amplifiers may be similar to their vacuum-tube cousins, but when transistors are involved, it is no longer necessary to use either transformers *or* phase inverters. This comes about because transistors come in two flavors of opposite polarity: PNP and NPN. A signal which would increase current in a PNP transistor would decrease current in an NPN. To build a push-pull transistor amplifier, then, no phase inverter at the input is necessary. Just parallel two stages, using a PNP transistor in one and an NPN in the other, and the outputs will automatically be push-pull if the transistors' characteristics are matched.

This quality (and design trick) carries the polysyllabic name of "complementary symmetry," and several sets of PNP-NPN paired types have been designed for just such applications.

At the output, a similar trick can be employed, using what someone several years ago dubbed the "totem pole" configuration with two transistors in series, and output taken from the midpoint. The circuit for such an output stage is shown in Fig. 3. This circuit is adapted from one which has appeared in several editions of the GE Transistor Manual, and hardly anything in it is particularly critical. With conventional 150 mW transistors, it can produce up to 2W of audio, which is surprisingly loud and clear.

Push-pull amplifiers have a number of advantages for audio and whenever linear amplification is necessary (as for SSB). The

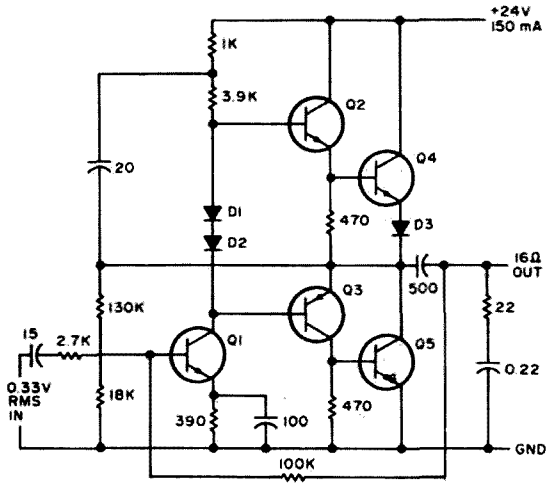

Fig. 3. This circuit for a 2.5W af power amplifier illustrates complementary-symmetry phase inverters (Q2 and Q3) as well as totem-pole output circuit (Q4 and Q5). Transistor Q1 is simply a preamp to provide drive to the phase inverter stage. A 100 kΩ resistor at bottom provides negative feedback. Diodes compensate for base-emitter voltage drops of transistors, making dc coupling safe to use. Transistors Q4 and Q5 must handle 800 mW dissipation; type 2N3402 transistors are simply 2N3414's with built-in heatsinks to raise power rating and are recommended for Q4 and Q5.

advantages are less pronounced when simple rf power amplification is needed, but some are still present.

One of the major advantages of the push-pull amplifier arrangement is the fact that it is a "balanced" amplifier. Any signals which are *in* phase with each other in both halves of the circuit, such as hum in the dc power supply, tend to be balanced out and are not passed on to the output. The same is true of second-harmonic distortion, and for that matter of all even-order distortion products.

The reduction of second-harmonic distortion because of its being balanced out permits us to choose between having less distortion for the same power output (the path taken by hi-fi designers) and having more power output from the same tubes without passing an objectionable distortion figure (the route taken by most hams).

The push-pull arrangement also permits us to operate the tubes or transistors over a wider range of conditions than would be possible with a "single-ended" stage. The class B amplifier is the extreme example of push-pull operation; a class B audio amplifier *must* employ the push-pull circuit to pro-

duce a recognizable output signal, since each half of the circuit works on only half the waveform. The popular class AB amplifiers are based on the same principles, only not to such an extreme degree.

With class C operation, these advantages disappear. The balancing out of second-harmonic distortion is still present, though, and permits us to emit a cleaner signal than we could from a comparable single-ended stage. Neutralization of a push-pull stage is also usually simpler than for a single-ended one, since the required out-of-phase neutralizing voltages are already present in the "other half" of the amplifier.

The Q-Multiplier

Although the Q-multiplier has been with us, under that name, since about 1950 or so (and under other names since the first vacuum-tube receivers were used in ham radio!) its operating principles remain a mystery to many of us.

This isn't too surprising, because it seems almost unbelievable that any device can be connected to a receiver by a single wire which serves as both input and output connection, and produce either a dramatic boost to one signal without affecting others, or an equally dramatic decrease in level of one signal (again without affecting the others).

And this bit of black magic is just what a Q-multiplier circuit does. It connects into the i-f amplifier strip of a receiver by a single connection, and you then have the choice of boosting one signal above the rest, notching out one signal, or having the device do nothing. The secret of this capability is an old friend to constant readers of this series—feedback. While uncontrolled feedback is normally a rather horrible and all-devouring monster, controlled feedback is, like fire, one of our most versatile tools. The Q-multiplier circuit is a device for generating and inserting a feedback signal, with complete control.

The name of Q-multiplier comes from the apparent effects of the circuit: When it is connected across any tuned circuit, the Q of that tuned circuit appears to be multiplied enormously (if the Q-multiplier is set to "peak" a frequency).

What the circuit actually amounts to is a way of picking out a sample of the signals present, and feeding them back over the same wire with controlled amplitude and phase. If the "peak" function is in use, the phase of the signal sent back to the i-f strip is such as to produce positive feedback, or regeneration. If the "null" function is selected, the phase is reversed to provide negative feedback, or degeneration.

The Q-multiplier contains, within itself, a tuned circuit of high Q to which the regeneration is also applied. This tuned circuit inside the Q-multiplier effectively substitutes for the original tuned circuit in the receiver, when the "peak" function is selected. The signals to which the Q-multiplier's internal tank circuit are tuned are not affected by the Q-multiplier at all, but any signals at adjacent frequencies (which would have been passed by the original receiver tuned circuits) are shunted out by the much higher selectivity of the internal tank.

When the "null" function is selected, the operation is a little bit different. The signals to be notched out are amplified by the internal tank just as in the "peak" operation, but they then pass through a phase inverter inside the Q-multiplier before returning to the i-f strip. The signal which was peaked up by the internal tank is, of course, the only one which goes through the phase inverter because the tank's selectivity has eliminated all the others from consideration, so it is the only one which is reversed in phase. When this signal in reversed phase is returned to the i-f strip, it cancels out the original signal. The other signals in the i-f passband are not affected, though. The result is to notch out the signal to which the Q-multiplier is tuned, without effect on the remaining signals.

The confusing part about operation of such a circuit, in either mode, is the fact that input and output travel over the same wire. How, then, if phase has been reversed for the "null" function, can the signal be present as an "input" to produce the action?

To explain this, we'll have to digress slightly into general servomechanism theory. While most persons think of "servos" as mechanical items in airplanes, or something equally far from ham radio, in truth any

circuit using controlled feedback is a servomechanism. A "servomechanism" is defined as "an object controlled, either in whole or in part, by the effects of its own operation"—and since feedback produces at least partial control of a circuit's operation by the effects of the output, it qualifies.

In a servo, the normal situation is to establish a "reference" signal. The servo's output is then compared to the reference, and an "error" signal results which tells how far the actual output is from the desired reference output, and whether it is greater or smaller. The error signal is then applied to the control portions of the servo, which are set up so as to attempt to drive the error signal to zero. If this occurs, it means that the actual output and the desired output are identical.

But, unfortunately, if the error signal ever does actually get down to zero, the servo is no longer controlled. The only thing holding it under control is the error signal's existence, and when it does succeed in forcing the error to nothing at all, the control disappears at the same time. Such a situation is known as "dither," "jitter," or "hunting." With no control, the servo circuit may do anything. As soon as it does, of course, the error signal reappears, and control is restored, but if the error signal is allowed to reach zero very often, the output will fluctuate whenever it does so. The "hunting" or "dither" describes the action which results.

The standard way to prevent the problem is to introduce just enough delay into the servo's feedback loop so that no matter what happens, the error signal can never completely disappear. This assures that hunting cannot occur, but the feedback will still make the error signal as small as it possibly can. In most cases, this is too small for us to measure directly. If we tried to do so, we would conclude that the error signal had indeed vanished—but the fact that hunting is absent indicates that enough error signal remains to keep the circuit controlled.

The Q-multiplier is a servo, of course, and when we set it up for the "null" function, we are in effect setting up the input signal-to-be-notched-out as the error signal. The circuit picks this specific signal out of its many possible input signals, and reverses its phase to cancel it out. If it should succeed in complete cancellation, there would be no input left to reverse in phase, and action would fail. As soon as this occurred, though, the reappearance of the signal would put the circuit back into play. The net result is that the notched-out signal is *effectively* canceled, but just enough of it remains to permit the circuit to operate. The process is aided by the fact that the voltage and current waveforms of ac signals are not necessarily in phase with each other, and so the voltage waveform can be canceled while leaving some of the current waveform untouched. The necessary error signal can then be obtained, inside the Q-multiplier, by converting this current back to a voltage.

A somewhat similar circuit operating at audio frequency and using RC phase-shift networks rather than a tuned circuit is known as the "Select-O-Ject." It operates in essentially the same way, to produce the same result but at audio frequency rather than at i-f.

Since the width of the peak, or of the rejection notch, is proportional to the frequency at which the circuit operates, both types of circuits serve useful purposes. The Q-multiplier can select one desired phone signal out of several in the passband, or can reject one which may be causing interference. The Select-O-Ject can peak up the desired beat note for CW reception, or can reject a heterodyne caused by a carrier just off the signal you want.

Either is often used to substitute for a crystal filter in a communications receiver. The circuits, being based on active devices, can be produced at less expense than can crystal filters, and in addition they are capable of some operations which crystals cannot do (such as notching out interference which is almost exactly on top of the desired signal). One feature of these circuits which has not been emphasized much is the fact that any number of them can be connected to a receiver with little if any interaction. This permits several different functions to be in use at the same time, such as peaking up one desired signal, notching out another which is still causing interference, and (with the audio version) slicing out several remaining traces of carrier whistle. However, oper-

ation of several at the same time might require the services of several trained octopi. . .

What Indicates A Gassy Tube?

From time to time we are impressed by the "gobbledegook" turned out in Washington, and the question in the FCC study list on which this discussion is based is one of the more notable gems: "What visual observation within an operating vacuum tube's envelope would indicate that the tube is gaseous?"

Apparently the anonymous government employee who worded this question was so fearful of using "jargon" in the list that he avoided the normal technical phrase "gassy" to describe a tube containing unwanted gases rather than the normal high vacuum—but the word he chose to replace it, unfortunately, does not mean the same thing. Since the three states of matter are solid, liquid, and gaseous, we would have to assume on the face of things that the tube under consideration is neither solid nor liquid. In that case, the most likely visual indication would be an inability to see the tube, wouldn't it?

However, we don't think that is what they really meant. It appears much more likely to us that they really want to know how you can tell a tube has gone gassy by looking at it—and Washington is not alone in sometimes using two dozen ten-pound words where a half-dozen everyday ones would do better.

Tubes go gassy for a number of reasons. The most normal is for some of the chemicals in the coating of the cathode to eventually break down under the high temperatures at which the cathode operates, and release gases. At least as frequent, though, in ham operation, is for the tube to be overloaded to such a degree that one or more of the tube's elements is actually vaporized, thus releasing gas. Screen grids of beam-power transmitter output tubes are particularly prone to this occurrence.

When a tube goes gassy, it no longer operates as it was intended to. The grid cannot control current flow when the gases ionize. This characteristic is made use of deliberately in the thyratron tube, and in a

CAMP ALBERT BUTLER INVITES HAM RADIO ENHUSIASTS OF ALL AGES
TO TRY FOR YOUR
GENERAL CLASS TICKET
THIS SUMMER! OUR 11TH SEASON
STUDY INSTRUCTION LEADING to GENERAL ADVANCE and AMATEUR EXTRA LICENSE

This co-ed Amateur Radio Camp, Y.M.C.A. owned and operated, can accommodate 60 campers. There is no age limit. We have had campers from 7 through 74 years of age. It is very helpful if you can copy 5 wpm or have a Novice or Technician ticket, but it is not necessary. Time is divided between radio classes in code and theory and the usual camp activities, such as swimming, archery, riflery, hiking, etc. Golf privileges are included at the beautiful New River Country Club course.
Entire staff consists of licensed hams who are instructors in electrical engineering in some of our finest colleges and universities. Camp opens August 1 and closes August 15th. Tuition of $200 includes all camp expenses: room, meals, notebooks, textbooks, and insurance. Send for our brochure.

C. L. Peters, K4DNJ
General Secretary
Gilvin Roth Y.M.C.A., Elkin, North Carolina

Please send me the Booklet and Application Blank for the Camp Albert Butler Radio Session.

different way in the controlled rectifier. In general, though, a gassy tube must be replaced.

When a tube does go gassy, it usually lets you know immediately by glowing bright blue. This blue glow is produced by the gas ionizing under the impact of the electron stream, and is the most obvious visual indication of gassiness.

However, not all tubes which show a blue glow are gassy. If the glow is only at the inside of the glass envelope, it's more likely to be a fluorescence of the glass itself under electron bombardment. Many modern tubes show this effect, but it does not indicate gassiness.

Some tubes, also, exhibit a faint blue glow in the space between the cathode and the plate, even when operating normally. This is, again, fluorescence, but this time it's from the tube elements themselves.

The glow of a gassy tube, on the other hand, fills the space from cathode to plate, and is much brighter than any glow in a normally operating tube.

Some high power transmitter power supplies use mercury vapor rectifiers. These rectifiers are built with gas in them, and use it as a part of their normal operation. They also serve as perfect examples of what a gassy tube looks like. If any tube which is *not* a mercury-vapor rectifier begins to look like one, it has probably gone gassy. Or, if you prefer, it "is gaseous."

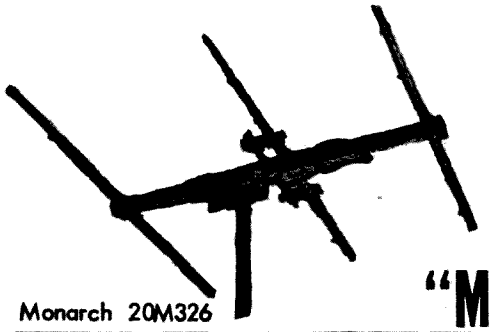
Rules and Regulations

The final question on the study list isn't a question at all, but an admonition: "Be familiar with Part 97 of the Commission's rules."

In this study course, we have taken great care to sidestep the details of the rules wherever possible, for one major reason. While the details of radio theory remain relatively constant, and are just as true today as they were five years ago or will be five years hence (although new discoveries may alter a few of the fine points, or provide additional understanding), this is not true of rules and regulations.

Rules and regulations are constantly subject to change. Right now we are in a period of transition which sees the permissible operating band limits changing every year—and a number of petitions before the FCC to make other changes.

Our intent in publishing this study course was to provide reference material. To do this, we felt it necessary to concentrate on that part of the examinations which would not be subject to change at the will of a regulating agency.



But it *is* important that you know the rules and regulations, as they exist at the time you take the test, if you want to succeed in obtaining your Extra Class ticket. While most of the emphasis is on theory, the fact remains that the top grade license requires a top grade of knowledge in every facet of ham radio.

So, before taking the exam, get a copy of at least the pertinent parts of Part 97 of the FCC rules and regulations, and brush up. You can order Part 97 complete from the Government Printing Office, or you can buy an up-to-date edition of the ARRL license manual. If you don't like spending money, you may be able to find a copy of Part 97 in a large library or in the files of some friendly commercial radio installation (FCC rules are bound in volumes, and normally you can buy only a complete volume; many commercial installations have copies of Part 97, as a result, in the volumes which they bought to get the rules applicable to their own service).

Key things to know are the effective band limits for each class of license and for each type of emission (and don't forget the UHF and EHF bands while you're at it), the restrictions which may be applied to ham operation and why, and the prescribed procedures for identification of all kinds of ham signals. Also important are the restrictions on types of messages which may be transmitted and received, and under what conditions these restrictions may not apply. Notification of portable and mobile operation, operation by aliens, and operation away from the U.S. jurisdiction may also be items worth being up to date on.

So there you have it. Good luck, and congratulations to you for your determination to obtain the top grade of all ham licenses.

. . . Staff ■

Crystal Plea

I am a prospective Grade II (5 wpm) ham (expecting my license). Maximum power allowed is 25 watts in the 14000 to 14350 kHz amateur band. In our country, ham equipment is not available for sale. However, I have managed to procure one junk Hallicrafters SX-28 which is in working condition. I hope I shall be able to rig up a 25 watt transmitter using two EL84s (6V6) as final amplifiers. But, a stable vfo will be prohibitively expensive for me to assemble, and crystals are just not available. I understand that war surplus crystals are available at a nominal price in the U.S. Kindly help me to locate a ham who is willing to send me a few war surplus crystals. It will be convenient if the crystals are of the type that can be plugged into standard octal sockets and the frequencies are in the range of 7000 to 7100 kHz so that I shall be able to operate in other bands (14000 to 14350, 21000 to 21450, and 28000 to 28700) by frequency multiplication when I am qualified for Grade I (12 wpm).

Maltese Directory

I am a Maltese ham living in Canada for the last 20 years, I still have an active 9H1AW call, also a G3WJL active call. During the last few months a number of Maltese hams from England, Canada, U.S.A. and Australia have asked me to create a book of as many Maltese hams as I can find; therefore I wish to say "Any Maltese emigrant to any country in the world who holds an amateur license) please write to; George N. Muscat.

Windsor 22, Ontario, Canada

CB vs Hams

As a county Civil Defense director, I work with both groups and from where I sit there is no conflict involved. I have been involved with a number of emergency situations using both services and have found both groups, in a pinch, willing to do anything they possibly can to help.

First, there are just not enough hams, particularly those with mobile equipment to make much of a dent in the crying need in an emergency. As an example, in this county of roughly 25,000 souls, we have about a dozen licensed hams, most of whom are inactive. Back in the late 50s and early 60s we bought a dozen Gonset Communicators and issued them to the members of local clubs. This was about the same time that CB made its debut. Since that time interest in ham radio has lagged, and CB use has increased. At the present time there are a half a dozen 6m Communicators stacked in my office available to any local hams who will keep them operable. Most of those who presently have them do not have mobile antennas on their cars and probably would have to look around for anything more than a piece of loose wire to cut to length (after digging up an outdated handbook for the proper dimensions).

On the other hand, we have something in the neighborhood of a hundred CB operators, many of these with mobile units. I might add that I'm referring to solid citizen type of CB users rather than the irresponsible type commonly equated with CB.

On a number of occasions, I have found CB an answer to a highway accident I have been involved with personally or in obtaining aid for someone else. Ham radio would have been out of the question because the coverage just *was not there*. In one case, a life was saved because there was someone on the air to take a call. Ham radio facilities were nonexistent and CB was the only available answer.

After the close of WWII, ham radio made some great steps and enthusiasm was at an all-time high. Now, with incentive licensing and other factors that contrast with CB, ham radio does not have the glamor it formerly had and the interest is lagging.

My personal feeling is that an updating of the ham radio licensing structure in line with the state of the art and the civil rights laws just to mention a few of the many.

April Cover

It was quite a surprise to see our building and television towers on the cover of my April 73. The Sandia Television Corporation operates this building. We arranged to allow WA5JDZ to install a repeater in the building and operate there free – including power.

Television stations KOB and KGGM-TV share this facility, as you might guess by the two TV antennas shown. The two domes are microwave dishes for a cable feed down south to Roswell. The little white house in the middle is a weather station which the personnel maintain for the weather bureau – the highest weather station

RG 196 AU 50 ohm teflon coaxial cable. Outside diameter .080" RF loss .29 db per foot at 400 Mhz. Silver plated shielding and conductor. Used for internal chassis wiring, antenna coupling, RF coupling between stages, etc. Random lengths from 35 foot to 150 foot. Colors: black, red, brown, blue, gray, orange. Regular price- 23¢ per foot. Our price 5¢ per foot $3.00 per 100 ft.
455 Khz ceramic filters type BF-455-A. These filters will help to sharpen the selectivity of most sets using 455 Khz IF's. Use across cathode bias resistor in place of a capacitor, or in transistorized sets, across the emitter bias resistor. Impedance is 20 ohms at 455Khz., DC resistance is infinite. Impedance increases rapidly as you leave 455 Khz. Plan your own LC filter circuits at very low cost.
10 for $1.00 25 for $2.00

TOROID POWER TRANSFORMERS

T-2 This toroid was designed for use in a hybrid F.M. mobile unit, using a single 8647 tube in the RF amp. for 30 watts output. Schematic included. 12 VDC pri. using 2N1554's or equivalent. Sec. #1 500 volts DC out at 70 watts. Sec. #2 -65 volts DC bias. Sec. #3 1.2 volts AC for filament of 8647 tube. Sec. #4 C/T feed back winding for 2N1554's. 1¼" thick. 2¾" dia. $2.95 ea. -2 for $5.00
T-3 Has a powdered iron core and is built like a TV fly back transformer. Operates at about 800 CPS. 12V DC Pri. using 2N442's or equivalent. DC output of V/DBLR 475 volts 90 watts. C/T feed back winding for 2N442's. $2.95 ea. -2 for $5.00

Burn Baby Burn

Surpressing a great desire to "keep my mouth shut," I would like to express my viewpoint about a few remarks made in the February and April issue of "73," concerning the Technician class licensee by Dave Mann and Wayne Green. I take no particular personal exception to the remarks of "73" as I am not a Technician and because I believe that such articles are in keeping with the basic philosophy of "73," i.e. that everything printed in "73" may not be "gospel," but that if enough readers' minds are stimulated and challenged, some solutions and "truths" may emerge.

Basically, I agree with Misters Green and Mann that some change is necessary. I do, however, feel that Dave Mann and Wayne Green may have gotten a little carried away in trying to show cause. The examples given to prove the Technician class licensee as unworthy of the distinction of amateur, apply to every class of license. To lack character and integrity is not only a weakness found in SOME Technicians, but in SOME General, Advanced, and Extra class licensees. To imply that a Technician gets his license by cheating is not only irresponsible journalism but is lacking in good sense.

It would be well to note that those Technicians, Novices, and Conditional class licensees who gained their ticket by cheating did so with the knowledge and consent of some higher (?) class licensee. And, oh yes, the higher class licensee, in the spirit of our fraternity, took nothing (much) for this service. Perhaps, we who saw practices like this and did nothing are just as guilty as those involved.

I certainly hope that the Technician or Novice that tunes in on the General, Advanced, or Extra bands, doesn't judge all of us by the occasional "lid" or loudmouth that gets on. If a problem exists and that problem deals with infractions of the law, then enforce the law. If a program is a failure or not relevant any longer, then *replace* it with a better program. Don't spend time running down a fellow because he doesn't have as high a grade license as you or because he took advantage of a program authorized by the government even though it may not be your "bag." The same, I might add, applies to the CB'er.

This "higher than thou" attitude reminds me of a club 18 years ago that no longer exists. The club's attitude was if a fellow wasn't at least a General, he wasn't anything. And, of course, we had that asinine philosophy of "well, if I did it, he can do it" to put up with. I need not go into detail to describe why the club died.

As for Technicians operating on 10 meters, the only time 90% of us "high" class amateurs get on is when the band is open. I, for one, would certainly like to see some regular activity on this band, CW or phone.

As for the "before the examiner" jitters, I can recall when I got my General ticket the FCC examiner refused to allow a blind fellow to use a typewriter for the exam. He made him "write" it. The examiner then "flunked" him because he couldn't read the writing. I also recall a friend of mine who had gone with me to take that test. He was so nervous that he could hardly hold on to his pencil. In both cases, both were qualified but for different reasons unable to perform before Big Brother. Fortunately for the Technician license, they were part of the amateur fraternity until each made the General. This was reason enough for the Technician license.

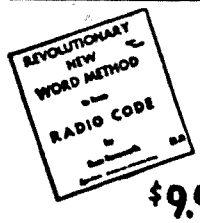
Attitudes as expressed by 73 concerning this particular topic do not in my mind reflect the best interests of amateur radio if we are to believe what we read elsewhere in 73. We have more than enough groups to go around. We are divided enough. We need to be pulling ourselves together if we have any hope of preserving amateur radio.

73 makes with a lot of noise while ARRL has its head in the sand and CQ wanders aimlessly denying everything. Well, pass the fiddle around and "burn, baby, burn."

Rev. Peter Gonos K6GZN
1803 Second Street
Concord CA 94520

There is one big difference: At 73, we really care. The big noise is because we're concerned. A head in the sand is protection for the head, of course (which is almost useless without a body); and we don't need to tell you that aimless wandering doth not bring forth fruit. Ah, but a big noise. . .that's something else again. You, good Reverend, have written a letter; is that not a start?

. . . Ken



Anti-ARRL Editorials

Ken stated in his editorial, "It doesn't take a genius to figure out that if every dissatisfied ham dropped his membership, the ARRL would either change or drop out itself. Your most powerful voice is not your ARRL membership; rather it is the abscense of it." Following this reasoning it follows that if you don't like the way the country is run, the thing to do is denounce everything it does and disregard what it says. If you agree with this reasoning there is nothing wrong with the League, rather there is something wrong with K6MVH/1.

Concerning hams who don't believe (belong to?) in the League. The FCC welcomes comments from the hams (no discrimination against non-Leaguers) before it takes action on its dockets or rulings. Thus, all amateurs have a voice on issues that affect all amateurs; all they have to do is use it.

Rather than denounce the League while offering no real solution why don't you have a proposal printed in your magazine which could be sent to you to give basis to your editorials and then forwarded to the League for their consideration. Or doesn't due process appeal to you? I think 73 would have more constructive influence if it presented all the facts on specific issues with which you disagree and then urge your readers to write to ARRL expressing their ideas on the subject. I think that the ARRL reads all the mail

it receives without concern to whether or not it was sent by a member. Doesn't that seem reasonable.

James M. Szot WB2VVZ
423 Lord Street
Dunkirk NY 14048

It certainly does seem reasonable. But have you any particular reason for believing the ARRL reads all the mail it receives without concern to whether or not it was sent by a member? I have proof positive, in case after case, that this is simply not the way it really is.

And why do you equate the League with the Country. I am a citizen of the Country, as is every individual born here. But I am not a member of the League, and to become one, I must pay the money. Would it not seem more reasonable to equate the League with a church? The League is but one denomination of a possible number of denominations. Yet, the League has the power to influence rulemaking for all people, be they members of that denomination or not. To me, it is like the Catholics having power to impose laws about not eating meat on Friday.

. . . Ken.

Newsbeat

I like the *"Amateur Radio News Page"* at the front of your magazine – very clever – keep it up.

Kelly W2ICE

Sour Grapes

At the risk of offending my successor as editor of this illustrious magazine, I am appalled at the lack of checking in the lead article in the April issue. It does not have the quality of an April Fool article, but it sure fools me.

The text refers to D1, D2, and D3. There are indeed three diodes on the schematic, but they are not marked.

The first i-f transformer is not identified. What is it?

The text says it is absolutely necessary to retain the exact value of resistors and capacitors, but the values are not given.

The text, under adjustment and operation, refers to adjusting voltage at point A. Where is this point ("A")?

I could go on and on. . .but I'll let you reread the article and check the schematic. When there was only one name on the masthead other than the publisher, we had a few complaints about errors. Now the masthead is full, and there should be someone about the premises who could compare the text with the diagram and make some sense of an article.

The title of the article, "A Noise Blanker that Works," is only true if you can give the reader the important details to make it work.

Kayla Hale W1EMV
Box 548
Port Salerno FL 33492

Let's face it. . . I'm incompittant.

. . . Ken.

Kickback

I am compelled to voice my sincere appreciation for Bob Manning K1YSD and his writings

in opposition to the critical letter from Jim Wagner in your April issue.

In today's world of canned media, Bob's original talent and sharp cracks at amateur radio's nuttier characters remains as one of the few sources of a really good laugh. I have just reread "Vidiots That Have Known Me," and have received just as much pleasure from it as upon the first reading. I hate to think that anyone would wish to have all humor removed from the pages of 73.

Manning's style of language is not vulgar, but reflective of true life and effectively hilarious. His "caliber of thought" is the highest kind of satire and wit, on a level that perhaps eludes some of his critics. No doubt Mr. Wagner was so shocked and repulsed by Bob's article that he felt compelled to read every word.

I know that the editor will not succumb to the "one in every crowd," and I only hope that Bob Manning will continue his contributions to this magazine that is enjoyed by so many.

Jerry "Ron" Johnson WA5RON
224 Roberts Hall
Austin TX 78705

Reference the "Letters" column in the April 1970 issue. Specifically a letter titled "Ban the Book" by Jim Wagner, taking issue with an article by Robert Manning K1YSD.

Mr. Wagner feels that K1YSD's articles are out of place in your magazine. I disagree. K1YSD's articles fit your magazine to a tee.

Let's not have fewer articles by K1YSD, but rather, more of these interesting and highly educational (?) pieces. He's the best thing you've got going for you – except perhaps Mr. Green's comments on the condition of the universe, et al. Both writers are highly amusing, though I must admit I do laugh more at Manning's stuff than I do at Green's – still they're both good.

Stan Poland WB0ABE

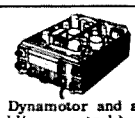
73 on the March

I would like to commend someone for the most imaginative magazine cover I can recall for some time, if not all time. i.e. March 70. I enjoyed that almost as much as the contents, and that is a broad statement.

Dan Wilhite
Argenta Lumber Company
North Little Rock AR



Just got and read the March Surplus issue. Wonderful. Best value for the money is your magazine. Kyle's article on surplus logic is priceless. I've been looking for down-to-earth info like this for a long time. Now – if someone will just tell me how I can tell if an unmarked diode is or is not a Zener!

NEW G&G CATALOG!
MILITARY ELECTRONICS

24 PAGES, crammed with Gov't Surplus Electronic Gear - the Biggest Bargain Buys in America! It will pay you to SEND 25c for your copy - Refunded with your first order.

BC-645 TRANSCEIVER 15 tubes, 435 to 500 Mc. Easily adapted for 2 way voice or code on Ham, Mobile, Television Experimental, and Citizens Bands. With tubes, less power supply in factory carton, BRAND NEW..... **$16.95**

SPECIAL PACKAGE OFFER: BC-645 Transceiver, Dynamotor and all accessories, including mounting, UHF Antenna Assemblies, control box, complete set of connectors and plugs. Brand New **$26.95**

AN/APR - 4Y FM & AM RECEIVER "FB" for Satellite Tracking! High precision lab instrument, for monitoring and measuring frequency and relative signal strength, 38 to 4000 Mc, in 5 tuning ranges. For 110 v 60 cycle AC. Built-in power supply. Original circuit diagram included. Checked out, Perfect. LIKE NEW..... **$88.50** All tuning units available for above.

DUAL AMPLIFIER
Has two input circuits, each feeding a single 6SN7GT twin triode amplifier. 115 V 60 cy. power supply. Finest components. Size: 5¾"x2¼"x4½". Weight 11 lbs. Brand new, SPECIAL **$7.95**

WILLARD 2-VOLT STORAGE BATTERY
Rated at 20 Amp.-Hours. Model 20-2. Rechargeable. Compact nonspill construction. Lightweight polystyrene container, 3x4x5¼". Shipped dry, uses standard electrolyte. Shipping Weight 3 lbs. NEW, each **$2.79**

BC-605 INTERPHONE AMPLIFIER
Easily converted to home or office intercom system! Uses pair of 1619 tubes, delivering 10 watts of audio power. Massive construction, suitable for shops, factories. Finest parts used Conv. diagram and instr. included. BRAND NEW ..... **$2.45** Excel. Used $1.95

HEADSET
Low impedance. With large chamois ear cushions. 4-ft. cord and plug. Reg. $12.50. OUR SPECIAL PRICE ..... **$2.95** High impedance adaptor for above . . . 69¢

How to Build and Tune Antennas
Work more DX with the right antenna for your location. New book gives step-by-step instructions (176 pages, 200 illustrations) for building every type of antenna: long wires, dipoles, yagis, trap, etc. Plus many others not described elsewhere: low cost miniature beams from converted TV antennas; indoor beams; "invisible" antennas; window sill antennas; 40 meter beams; vertical beams; Novice Band DX; many, many others. Secrets of tune-up of both manufactured and homemade antennas for greater DX. How to use antenna test gear. Buy book "Ham Antenna Construction Projects" at your "H.W. Sams" distributor. Only $3.95. Or for autographed copy, send $1.00 (cash, ck, or m.o.) direct to author, J.A. Stanley, 855 South Fillmore Street, Denver, Colorado 80209. Pay postman balance COD plus postage. Or send full amount for post paid delivery. Money-back guarantee.

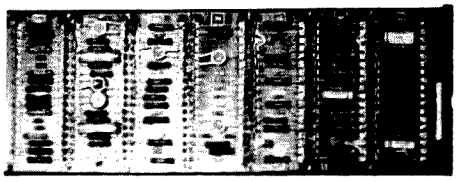
ALL BAND TRAP ANTENNA!
Reduces Interference and Noise on All Makes Short Wave Receivers. Makes World-Wide Reception Stronger. Complete with 96 ft. 72 ohm feedline. Sealed resonant traps. For novice and all class radio amateurs! Eliminates 5 separate antennas with better performance guaranteed 80-40-20-15-10 meter bands. Complete 102 ft. $19.95. 40-20-15-10 meter bands, 54 ft. (best for world-wide short wave reception) $18.95. Send only $3.00 (cash, ck, mo) and pay postman balance COD plus postage on arrival or send full price for post-paid delivery. Complete instructions included.
For ALL Amateur Transmitters. Guaranteed for 1000 Watts Power. Light, Neat, Weatherproof.
WESTERN ELECTRONICS Dept. A Kearney, Nebraska 68847

the only time I came to grief on this was with those Italians and the U.S. stations. I knew the U.S. operators understood English, so the only explanation for their behavior was that they just didn't care one bit what I or anyone else thought of them. I made only a small fraction of the U.S. contacts that I might have otherwise. Oh, I tried splitting frequencies, and this worked at some times. The best results to the U.S. were when conditions were marginal and only a few stations were coming through. When the band was wide open with hundreds of stations wanting to get through they were not about to work with any system whatever – prefixes, lists, or anything else.

You know it only takes about two persistent stations to absolutely ruin a good band opening like that. One station in Brooklyn flatly refused to permit me to work from a list and he called in constantly every time I tried to stand by for anyone. I was so busy trying to hear through him that I neglected to write down his call ... too bad ... I sure would like to let that louse know what I think of him and how many dozens of stations he prevented from working JY1.

Even so, I contacted hundreds upon hundreds of U.S. stations, and as I said earlier, I doubt if anyone that seriously needed JY1 missed it.

I even had the surprising experience of being snubbed. I heard VQ9CD calling CQ U.S. from Chagos so I broke in and called him ... he absolutely refused to answer me!



Though I didn't stop to count, I am sure that JY1 is well over the 100-country mark. Every now and then a rare one would call in through the pileups.

The original aim of getting JY1 well worked so His Majesty could sit back and enjoy hamming was achieved, I think. Although I am not so sure that this is of as great importance now as it was when I arrived. His Majesty sat for hours watching me operate, and spelled me when a particularly obdurate Italian would wear me down a bit. During the all-night stint His Majesty sat there right up until we closed down at 7 a.m.! And he enjoyed every minute of it. As my time for departing came closer I noticed that he was getting to be able to handle pileups very well ... and enjoying them!

After two weeks of almost daily contact with His Majesty it is hard to think of him as a King ... he is a friend. When you run into him on the air please be considerate so we can keep him a friend of our hobby. You just might go out of your way a little when you hear him operating to watch over him and protect him from the inconsiderate.

At the request of His Majesty I outlined a set of amateur radio regulations that are custom-made for Jordan. The Royal Jordanian Amateur Radio Society is in the process of being established with His Majesty as honorary president and Mrs. Salti as the secretary. My proposal calls for

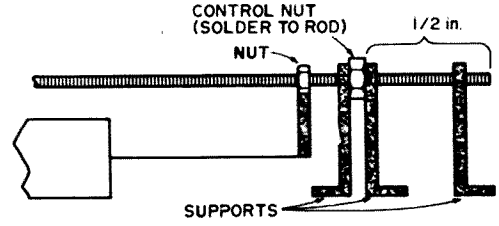
two classes of license for Jordanians, a Class B and a Class A. Both would require five words per minute code speed, with the Class B permitting restricted power operating in the CW bands on 80-40-15-10, plus phone on the VHFs. The B license would be similar to our Novice in difficulty and the A would be more like our General.

I also proposed a special visitors license good for ten days and a license for aliens resident in Jordan, both requiring valid home amateur licenses.



There seems to be good reason to believe that these beginnings will bear fruit. I outlined the plan to an assembly of the General of the Army, the General of the Air Force, the head of the Royal Auto Club (I also wrote in permission for mobile operation), the Minister of Communications and other dignitaries. One or two shuffled their feet and wanted time to study the matter and think about it, but His Majesty urged speed, and His Majesty is His Majesty and what he wants happens.

For those of you who have the opportunity to contact Hussein (as he calls himself), you might keep in mind that he is an ardent flyer, has quite a bunch of cups for racing and hill climbing in his Porsches, enjoys skin diving, skiing, water skiing, and you name it. If you have nothing to talk about with him it is your lack of interests, not his. Let me also clue you that a person with a wide range of interests like that will be interested in your field of expertise, whatever it is.

. . . W2NSD ■

More Accuracy on Microwaves

There are undoubtedly a few readers who would like to construct the microwavemeter that appeared in the December issue of 73. With a slight amount of exterior modification greater accuracy can be obtained, as well as some protection against bent plunger fingers.

The modification consists of adding a thumbscrew drive for slower, smoother tuning. First, solder the plunger rods to a brass plate. To this solder a vertical support topped off with a hex net; 4-40 or 6-32 is all right. Fashion three supports with holes high enough to pass a threaded rod parallel to the base. Solder a hex nut to a 4 in. threaded rod as shown. Thread it through the plunger nut, then align the supports and fasten them to the base. Attach the pointer as per the article. Pull the plunger out as far as possible before attaching the threaded rod. Be sure that the two supports near the control nut are as close together as possible to prevent any horizontal movement of the control rod.

. . . Stephen Goldstein

(continued from page 19)

rough going since all the problems of a couple of years ago, and there's nothing like a Gus Browning outing to reawaken the too-long dormant DX bug.

One of the problems which has resulted from the division of our bands into segments is the apparent ignorance of some foreign DX operators with respect to the allocations. Many of these stations have been heard working W/K contacts in the Extra Class/Advanced frequency segments, and the General Class DX'ers have been forced to wait endlessly with their tongues hanging out. I actually heard a DXpedition recently, calling CQ for contacts, and he announced that he was listening 14.210 to 14.225. He had virtually no takers, yet there were dozens of fellows calling above 14.275, whom he didn't even know were calling him.

If the available DX is to be the sole province of the higher class licensees, and if the Generals are not going to be considered by expeditions as worthy of contacts, then the restructuring is even more diabolical than it first appeared to be.

It is one thing to establish restrictions under the principle that incentives will tend to provide impetus for individual achievement. But it is quite another thing to fail, after this restructuring, to advise all foreign hams, through their official organizations, whether affiliated in some confederation or not, that the change has been made. It is only in this way that these operations will be split up so as to afford an even break to those who can no longer operate on the low ends of the bands.

If this situation is permitted to deteriorate any further it is likely that those Generals who do not upgrade to Advanced will be forced out of the hobby altogether. It is no fun to be isolated from all others, and to be ostracized in this fashion. . .it is reminiscent of a sort of solitary confinement. And it does have the end effect of a kind of punitive punishment as the price of failure to upgrade. I'm sure that the FCC had no such intention when it imposed the new allocations. But, as the old saying goes, ". . .the road to Hell is paved with good intentions."

NO-CODE HAM "HOBBY" LICENSE PROPOSED

Washington, DC. A brand new class of amateur license – to be designated "Hobby" class – has been proposed for the central portion of the 220 MHz amateur band. This new ticket would require no theory and no code, but would involve an exam, administered by any General, covering FCC rules and regulations governing operation in the applicable spectrum.

FM Only

The Hobby license would permit the holder to operate with a power of up to 100 watts using narrowband FM (±5 kHz deviation) in the frequency range from 220.5 to 224.5 MHz. This license would be available for a fee of $5 for a five year period and would be renewable upon proof of use and a $5 fee. The 220.0–220.5 and 224.5–225.0 MHz segments of the band would still be open to higher classes of license as presently authorized, thus preserving one MHz of the band for exclusive use of the higher classes of license.

The use of FM techniques would eliminate the problems of heterodynes which contribute so much to the frustrations of the 27 MHz band and would provide simple network systems with squelch as is now popular on the 144 MHz band. Though tion would be within the 450 MHz amateur band and would also be unlikely to interfere with commercial bands. A 500 kHz "guard" band for higher class amateurs on each side of the proposed Hobby band would provide adequate isolation for errant operators to keep them from interfering with adjacent commercial bands.

Callsigns

In order to indicate the class of license by the call letters, a new set of callsigns would be established for the Hobby license using the regular amateur call areas, but starting with NA1AAA and going through to NZ1ZZZ, a system which would provide for over 4,500,000 callsigns to be issued. When a Hobby operator goes to a higher class of license the last three letters could be passed along to the WA1AAA type of call letter, thus preserving the identity of the operator through this counterpart call.

Something for Everyone

The Hobby license would seem to fulfill a number of needs without taking anything away from anyone. It would provide a legal hobby band which is obviously needed. It would help the Commission solve the problems of the citizens band. It would

Seven Club Stations for Jordan

King Hussein has ordered seven complete amateur radio stations for installation in Jordan schools, orphanages, and remote military bases. Each of these stations will run a full kilowatt into a three-band beam and should put out substantial signals.

The King, recognizing the importance of amateur radio to the development of Jordan, has authorized an amateur radio service for the country and a drive is on to attract people into the hobby. Equipment is difficult, if not impossible, to get in Jordan, so the seven club stations should provide a means for the first amateurs to get on the air and develop their skills.

The activity of these club stations should remove Jordan, once and for all, from the ranks of the rare countries. The first amateur license in Jordan is a CW-only ticket, which means that most of the early operation of these stations will probably be on that mode.

One of the club stations will be installed at a remote air base. It will be used by air force personnel who have passed their amateur license exams. The men at this base are far from any town or any other means of communications, so we should hear quite a bit from them on the ham bands.

Arrangements are being made for the operation of some of the club stations by visitors to Jordan, thus making it unnecessary for tourists to bring their own equipment in order to operate from this rare country. The 220V 50 Hz line power that is standard there would make it particularly difficult to use the U.S. ham gear and the wide variations in line-voltage equalizing equipment to protect the rigs.

Tourists visiting Jordan will be issued special calls starting with JYØ, while the Jordanian operators will have JY7 and lower numbers. Only the King will have a JY1 call.

King Hussein surprised the amateur fraternity by turning up on the ham bands early this year using a Drake station bought for him by his wife as a Christmas present. The station was installed at his home (Hummar) just outside of the capital city of Amman with the help of SVØWI, who came over from Athens. The King chose the call JY1 for his station and, as a result of many years of no amateur operations from Jordan, had his hands full at first giving the thousands of DX'ers

crystal control would not be required, it would probably be extensively used as it is for 144 MHz FM operations.

This Hobby license would provide a band where hobby operation is legal, and would thus free the 27 MHz band for business use as originally proposed by the Commission. The large number of channels available in the 220 MHz band would provide relatively interferend provide relatively intereference-free communications for the operators, offering them adequate reasons for changing from the 23 channels on 27 MHz. The coming dropoff in skip conditions on 27 MHz will work to the end of encouraging the changeover. This band, as with all other amateur bands, would be largely self-policing, thus removing a very expensive headache from the Commission.

Repeaters

The Hobby license would permit communication through repeaters, but a higher class license would be required for the installation and maintenance of a repeater, since technical knowledge is much more necessary for the installation than the use of a repeater.

The amateur 220 MHz band is above television channel 13, so interference to television reception would be unlikely. Second-harmonic radiation would not be a problem. The Hobby license would provide activity on a virtually unused amateur band. It would encourage an influx of new amateurs. It would provide millions of dollars in fees to offset Commission expenses with little overhead involved, since all of the examinations would be given by volunteer radio amateurs. It would encourage the development of commercial narrowband FM equipment for the VHF bands which would benefit all amateurs as well as users of adjacent commercial bands. It would encourage the development of fixed-station equipment, mobile equipment, portable equipment and hand-held equipment, autotuning receivers, autocall signalling equipment, etc. It would also give a number of manufacturers a very bright future.

1300-PLUS ATTEND N.Y. HAMFEST

Despite threats of rain, over 1300 amateurs gathered for the yearly Western New York Hamfest just outside of Rochester, New York on Saturday, May 16. The biggest drawing card of the hamfest was the acre or so of flea market. . .dozens of cars and trucks loaded to the hilt with equipment and parts. . .driving otherwise normal hams right out of their minds with bargains. One hundred capacitors for $1.50. . .vacuum capacitors for that 10 kW final for $3 ($5 if you want it motor-operated), and so forth. A lot of very valuable equipment (and some beautiful boat anchors) changed hands . . .all tax-free.

Inside the hamfest building the committee kept things humming with a steady stream of interesting talks, mostly VHF-oriented. The three ham magazines had booths set up and vied with each other for subscriptions and deals. QST was the only magazine absent. (The ARRL consistently refuses to support this valuable hamfest activity.)

The skies held dry for most of the day, and then late in the afternoon they tipped the heavenly bucket and down it came, folding the flea market and sending everyone into the building to finish off the last of the refreshments and jam the technical sessions.

Wayne Green was honored at a prehamfest meeting the night before where he presented the first showing of his slides of his recent JY1 trip, including photos of King Hussein operating his station in Amman, Jordan.

Wide-angle view of the Rochester Hamfest's flea market.

a new country. For the first few weeks he had to explain to virtually every contact about his unusual call. He never said it, but the answer that was intimated was, "Why not? . . .it is the King's station." Even the ITU agreed that they would go along on that basis, though the ITU regulations do call for some sort of suffix under other circumstances.

Delivery of the club stations is expected some time in July and they should be set up and in operation in short order after delivery.

Hy-Gain BUYS GALAXY

Hy-Gain Electronics Corp. announces that it is acquiring Galaxy Electronics as the result of stock trading within the two companies. As most amateurs know, Galaxy is a leading American produce of SSB and VHF FM transceivers. Hy-Gain has specialized in the manufacture of antennas and antenna systems for amateur, CB, industrial, and military applications.

According to Hy-Gain spokesmen, the shift in management will not affect existing Galaxy warranties or service policies. Also, no immediate changes in company personnel "are presently contemplated."

The major difference that should be noticeable to hams will be Hy-Gain's shift to a "systems approach" to the communications field, whereby the company will market "complete packages" for two-way radio use.

LONG RANGE PROPAGATION NEWS

by J. H. Nelson

We will soon be entering the unsatisfactory part of the SUNSPOT CYCLE which runs from about one year after maximum to about one year before the coming minimum. The highest monthly sunspot number reached this past cycle was 135.8 which was in March 1969. The coming low is expected to arrive in 1974 or 1975.

Experience has shown these periods to be unsatisfactory during the past three cycles particularly during winter evenings and nights and during the sunrise/sunset hours. However, conditions during the summer months are quite good during this period if the proper frequencies are used.

There appears to be general agreement among the people who predict sunspot high periods that the next high period which should come around 1979 or 1980 will be below normal by a significant amount. I have done some research on this subject myself using both their methods and my own long-range forecasting technique. My conclusions are similar. This can cause a significant reduction in the number of useful hours for 10 meters during the next high sunspot period.

British Steam Train Will Use U.S. Hams

This summer the British train *Royal Scotsman* will be touring the western portion of the United States advertising British-made products and giving the Americans a chance to see this famous steam-powered train. The Hallicrafters Company has decided to equip an amateur radio station on

Designation of Bands

The FCC says it is receiving inquiries concerning the exact meaning of various letters sometimes used to designate the limits of a number of frequency bands, largely in the microwave region of the spectrum. The use of these letter designators, such as L, S, and X, was initiated during World War II, primarily for security reasons. However, they still occasionally appear in electronic publications, both in technical articles and in advertisements, and are sometimes used in offices of some Government agencies. Largely, their use is confined to documentation dealing with radar, telemetry, and electronic countermeasures equipment.

A number of letter designator systems have appeared over the years and their use continues to generate confusion because of the lack of standardization, nationally or internationally. Difficulties arise because, in some instances, the band limits vary from one system to another, and none can be considered authoritative. Because of this, the FCC discourages the use of single-letter designations and says that it cannot answer questions regarding their meaning. Inquiries concerning them should be addressed to the source originating the information.

In the interest of avoiding confusion in this area, the frequency management interests in this country have for some years held the position that specific frequency bands should be cited in terms of their actual numerical frequency limits and have encouraged the public to do the same. For example, the U.S. FM broadcasting band is designated 88–108 MHz in our Table of Frequency Allocations, which precisely defines the band in terms well understood in the engineering and scientific community. In that connec-

ACTION IN DOCKET CASE

FCC's regulation of rf devices extended to sale, shipping, and advertising effective October 1, 1970; to implement 1968 law, reduce radio interference.

Manufacturers, vendors, and shippers of radio frequency devices that emit electromagnetic energy capable of causing harmful interference to radio communications must meet the technical standards of FCC rules after October 1, 1970. The new order implements a 1968 law empowering the Commission to make reasonable regulations governing the interference potential of certain devices. (Section 302, "Devices Which Interfere with Radio Reception," was added to the Communications Act on July 5, 1968, by Public Law 90-379, 82 Stat. 290.)

The Commission said that the purpose of the new rules is to require compliance with equipment standards by manufacturers, importers, and distributors of rf devices, as well as by users, and that the rules apply to many persons and companies not now directly subject to regulation.

The revised rules prohibit the sale, transfer, importation, shipment, or distribution of rf-generating devices unless the devices meet the Comnission's technical standards or have been type-approved, type-accepted, or certified. (Type approval is based on testing by the Commission; type acceptance and certification on testing by the manufacturer, his notification to the Commission, and the Commission's acceptance of the test results.) The Commission said that it is presently reviewing its regulations to determine what changes are necessary in its type approval, type acceptance, and certifi-

News, Reviews, Announcements

Free Award

A new award is being issued free to anyone who has worked all 17 Monroe counties in the United States. Send SASE to Max Holland, Hiwassee College, Madisonville TN 37354. No QSL cards needed to verify contacts. Just state whether contacts were on single band or all bands.

Zero-Beaters

The Zero-Beaters ARC Hamfest will be held on Sunday, August 2. Washington, Mo. City Park. For further information write or contact Zero-Beaters ARC, Box 24, Dutzow MO 63342.

MVARA Hamfest

The Mahoning Valley Amateur Radio Association will sponsor a hamfest Sunday, August 2 at Lions Park, New Bedford, Pa., located nine miles east of Youngstown, Ohio, one-half mile north of Hwy 422 on Rte. 932. Door prizes and flea market. Call-in freq. 146.94 and .34–.76 repeater. For information contact Frank Dodd K8UYF.

Glacier-Waterton

The 36th annual Glacier-Waterton International Peace Park Hamfest will take place in Glacier National Park, July 18 and 19, 1970. Amateur radio operators from Montana, Idaho, and Washington, along with good neighbors to the north – Alberta, Saskatchewan, and B.C. will gather to further a mutual interest in ham radio, and to just have fun. This is a biggie; don't miss it!

board the train, and is now in the process of lining up operators to man the station for all or part of the operating period, which will extend from June 14, 1970 until early August 1970.

A special callsign will be issued for this railroad mobile expedition and a special QSL will also be available.

A spokesman for the expedition said the train will leave Lubbock, Texas on June 14 and make its way across Texas, Oklahoma, Kansas, Missouri, and on to Chicago – then to Green Bay, Wisconsin, stopping at various cities en route. Amateur operators are needed to either ride on the train to operate the station or to help operate the station while the train is at rest in the various cities. Transportation on board the train as well as sleeping accommodations will be furnished at no cost. The spokesman said dining facilities will be available on the train. Meals will be taken at stops along the way and will be at the expense of the individual participants. Participants must furnish their own transportation to and from the location of the train.

Any licensed ham who would like to participate is invited to contact one of the persons listed below for further details as to schedules, times, dates, and places:

Archie L. Julian WB4CYR
6921 Fort Hunt Road
Alexandria VA 22307
(703-768-3412)

Jim Adams
1520 Wolfram Street
Chicago IL 60657
(312-935-1687)

Hoosier Hills

The Hoosier Hills Ham Club Hamfest will be held on October 11, 1970 at the Spring Mill State Park near Mitchell, Indiana. The main prize is to be a Drake TR-4.

tion, the number of digits required to describe bands higher in the spectrum may be reduced by using the nationally and internationally adopted term GHz which is equal to 1000 MHz.

Broader portions of the spectrum may be described by a nationally and internationally adopted series of widely used phrases, and their abbreviations, as follows:

Very low freq. (VLF)	3–30 kHz
Low frequency (LF)	30–300 kHz
Medium freq. (MF)	300–3000 kHz
High frequency HF)	3–30 MHz
Very high freq. (VHF)	30–300 MHz
Ultra high freq. (UHF)	300–3000 MHz
Super high freq. (SHF)	3–30 GHz
Extremely high freq. (EHF)	30–300 GHz

FCC Rules Amended Uniform Expiration of Licenses

A uniform expiration date for amateur operator and station licenses has been provided for by the FCC in an amendment to Section 97.59. The rules for the amateur service provide for issuance of an amateur operator license, and normally the amateur operator and station license expire on the same date. During the term of his basic license, however, should the licensee obtain an additional station license, the present rules do not show the Commission's current practice regarding the expiration date for additional amateur stations. The Commission said the amendment will reflect this practice, as shown in Item 5E (FCC Form 610), that the license of an additional station will expire on the same date as the operator license. The rule amendment became effective on May 1.

cation procedures in view of the new regulation.

Only one category of rf devices – incidental radiation devices, such as electric motors, automobile ignition systems, and neon signs – was excluded from consideration in this proceeding, the Commission stated, because technical standards governing their operation have not yet been prescribed.

Devices subject to Commission authority and included under the amended rules range from the many kinds of radio transmitters used in the broadcasting, common carrier, marine, aviation, and land mobile services to restricted radiation devices; wireless microphones; phonograph oscillators; radio-controlled garage door openers, models, and toys. Various types of industrial, scientific, and medical equipment such as ultrasonic, industrial heating, medical diathermy, radio-frequency-stabilized arc welders and miscellaneous equipment, are also subject to the new rules.

The Commission exempted the manufacture of rf devices from the new regulations, so as not to curtail research. It also exempted from the new rules transmitters operated in the AM, FM, or TV broadcast services, or in the Instructional Television Fixed Service, and certain Industrial, Scientific and Medical equipment governed by Part 18 of the rules, including industrial heaters. (Industrial heaters that generate less than 10 kW of rf are subject to the condition that the purchaser be notified in writing whether the equipment, as delivered, complies with the technical requirements of Part 18 or whether a shielded enclosure is required.)

In response to comments expressing fear of an adverse impact by the new rules on preproduction marketing of products still in the design and development stages, the Commission stated that the new rules will not "preclude the proposal or execution of agreements to manufacture or produce in the future new products in the design or development stages or products which are to be manufactured in accordance with designated specifications." Advertising for sale of existing rf devices before it has been determined that the devices meet Commission requirements is prohibited, however, the Commission said.

Michigan

The 17th Annual South Western Michigan VHF Picnic will be at the Allegan County Park, August 2, sponsored by the Van Buren County Amateur Radio Club, W8JUU, Bangor, Michigan.

Iowa

The date of the Iowa 75 meter phone net picnic has been changed from August 9 to August 16. The picnic will be held in Marshalltown, Iowa at the Riverview Park. Festivities will begin around noon with the frequency of 3970 kHz being monitored.

England

Becket Festival Station GB2CF will be active from Canterbury, England, during July 19 to 26 inclusive. This station will form part of the Becket Festival and QSOs, which will be QSL'd with a suitable card, will be most welcome.

QSOs with stations in the U.S.A. particularly in towns called Canterbury or any of the following local names of towns and villages which surround our city – would be most welcome:

Ash	Chilham	Bekesbourne
Bridge	Chartham	Faversham
Herne	Kingston	Herne Bay
Ickham	Selling	Littlebourne
Sturry	Stelling	Patrixbourne
Wye	Wingham	Wickhambreux
Aylsham		

Repeater Docket Comment Deadline Extended

As a result of requests by the ARRL and a Mr. Neil Murphy, the FCC has agreed to move the deadline for comments to Docket 18803 from May 15 to June 15.

The ARRL based its request for extension on (1) the scope and complexity of the subject matter and (2) delay in considering the proposal caused by "internal procedures." When the FCC issued its order, it did not elaborate on the meaning of the League's "internal procedures" statement.

Mr. Murphy stated that additional time was needed because of the complexity involved in "preparing a proper commentary."

The Conmission said that since the views and reply comments of interested parties might be useful in a subsequent rulemaking, additional time for comments seemed reasonable. In its order, released May 18, the FCC declared the conment deadline to be June 15, 1970, and the deadline for reply comments was rescheduled for July 7, 1970.

DELAYED LICENSES

A number of amateurs have complained that they have gotten letters from magazines seeking subscriptions or from companies hoping to sell them something, complete with their call letters on the address, before they have received their license from the FCC. Could this be? The following letter from the FCC tells us that it can be.

Acknowledging your recent letter, the Commission's Rules and the Public Information Act (P.L. 89-487) provide for the public inspection of all applications and related files in the Safety and Special Radio Services.

Several organizations make a regu-

Eighth Annual Illinois QSO Party

Starts 1600 GMT Saturday, August 1, 1970 and ends 2200 GMT Sunday, August 2, 1970. Use all bands, CW and phone. The same station may be worked and counted for a QSO point on each band and each mode. Illinois stations score 1 point per contact with stations either in or out of Illinois. Stations on county lines count only one point per QSO, the same as any other station. Stations outside Illinois score 1 point per QSO with Illinois stations. Illinois stations multiply total QSO points by the total number of states, VE provinces and ARRL countries worked. All others multiply total QSO points by the total number of different Illinois counties worked. Stations on county lines count as two or more counties. Additional bonus multipliers may be counted for working the same county. Each group of eight contacts with the same county count as an extra multiplier. (10 QSOs count as 1; 16 QSOs count as 2 multipliers, etc.) USA, Canada, Hawaii, and Alaska count as separate countries. KH6 and KL7 also count as states. Illinois stations give QSO number, RST, and county. Others give QSO number, RST, and state, province or country. Use approximately 3560, 3735, 3900, 7060, 7175, 7260, 14060, 14275, 21060, 21110, 21360, 28060, 28660 kHz and 145.2 MHz. In Illinois, single- and multiple-operator stations compete in separate categories, with certificates issued to first, second, and third place winners. Elsewhere, certificates will go to the top scorer in each state, VE province, and country provided that at least two valid entries are received from that region. Other certificates may be issued at the discretion of the contest committee. Decisions of the contest committee are final. Logs must show dates, GMT, stations worked,

New Jersey QSO Party

The Englewood Amateur Radio Association invites all amateurs to take part in the 11th New Jersey QSO party.

Rules: (1) The time of the contest is from 1900 GMT Saturday, August 15 to 0600 GMT Sunday, August 16 and from 1200 GMT to 2300 GMT on Sunday, August 16. (2) Phone and CW are considered the same contest. A station may be contacted once on each band – phone and CW are considered separate bands. New Jersey stations may work other New Jersey stations. (3) General call is "CQ New Jersey" or "CQ NJ." New Jersey stations are requested to identify themselves by signing "De NJ" on CW and "New Jersey calling" on phone. Suggested frequencies are: 1810, 3555, 3740, 3930, 7060, 7275, 14075, 14280, 21100, 21375, 28800 kHz, 50–50.5, 144–146 MHz. Suggest phone activity on the *even* hours. (4) Exchanges consist of QSO number, RST, and QTH (ARRL Section or country). N.J. stations will send county for their QTH. (5) Scoring: Out of state stations multiply number of complete contacts with New Jersey stations times the number of New Jersey counties worked (maximum of 21). New Jersey stations: W, K, VE, VO QSOs count as 1 point; DX stations count as 3 points. Multiply total number of points times the number of ARRL sections (including NNJ and SNJ – maximum of 74). KP4, KH6, KL7, KZ5 count both as 3 point DX contacts and as section multipliers. (6) Certificates will be awarded to the First place station in each N.J. county, ARRL section, and country. In addition, a second place certificate

VOX POP

Little Gleanings on 20

John ZK1AJ on Raratonga mentioned that ZK1AA has a 50 MHz beacon aimed at the states. That would be a nice one to hear. John's QSL manager is KH6GLU. SU1MA's QTH is Box 840, Cairo. JX4GN has been quite active of late, QSL to him via Norwegian Embassy, Reykjavik, Iceland. Odd also gets down on 3798 kHz. SVØWDD only active station on Crete, QSL to WQ3HUP if you contact Ray. Interesting development on Genada, a nonlicensed American has a ticket down there. I gather if you pay the fee you get your license. VP2GRN (Bob) and his wife Jeannie (VP2GNE) QSL via WQ4YHB. KJ6CD, Lew on Johnston, QSL to W6LTA. KG4AL is the only mobile in KG4.

QRP on 40

by WA8MCQ

Every Friday night at 2000 EST, the QRP net meets on 7080 kHz. Anyone with low power is welcome, of course, but so are those high-power boys who like to listen for the "flea-powered" stations.

Prayer Brings Astronauts Home?

The faith of the nation was strenghtened when the President asked all citizens to go to their knees in prayer for the safe return of the Astronauts. Now, hams who believe in prayer have the opportunity to be the vital connection between emergencies around the world and hundreds of praying people in their own communities.

The Wycliffe Bible Translators, a nonprofit, nonsectarian mission, has over 2000 workers in remote areas of the world translating the Bible in to tribal languages. With a team this size, there is an emergency every day – somewhere. In U.S. cities people want to know what the emergencies are so they can pray.

The Prayer Force Net has been established to communicate these emergencies. Any ham joining the net would meet one of four weekly scheds and relay the news by phone to one or more people in his community. From there a telephone net takes over.

Here is the Prayer Force Net schedule:

Tuesday	0030 Z	14.310 MHz
Friday	0030 Z	21.390 MHz
Friday (W Coast)	0330 Z	7.268 MHz
Saturday	1600 Z	21.310 MHz

If interested, simply check into the net, and other net members will help get your community organized. For info, write: Prayer Force WA6CJB, Box 2000, Santa Ana CA 92707.

exchanges sent and received, bands, modes, and claimed score. A summary sheet should be sent, showing whether single- or multi-op, name and address of operator clearly printed, QSO points, multipliers, and score. Logs must be postmarked no later than 1 September 1970, and should be mailed to the following address with adequate postage: Radio Amateur Megacycle Society, 3620 N. Oleander Ave., Chicago IL 60634.

Mayflower 70 Award

This award has been instituted by the committee governing the Cheshire Homes Amateur Radio Network Fund to commemorate the 350th Anniversary of the sailing from Plymouth the Pilgrim Fathers for America 1620. (The Homes care for the incurably ill and permanently disabled.)

The object of this award is to continue efforts to provide amateur radio equipment to the Homes. All profits from this award will be devoted to this purpose; no member of the committee will receive payment or reward for services.

The award is open to all ham operators and SWLs, and there is no time limit.

Any band or mode of transmission will be allowed; QSL cards need not be sent with claims, but a certified copy from the station logbook must be sent in with claims.

To Qualify for the Award

Operators in the U.S. must furnish proof of having had contact with one amateur station operating from Plymouth. Shortwave listeners must show verification of reception of one amateur station.

Certificates

The cost of certificates is one dollar, which includes postage by surface mail. Forward all claims to the award manager, W.M. Clarke G3VUC, Fillace Park, Horrabridge, Yelverton, Devon. PL20-7TE.

will be awarded when four or more logs are received. Novice and Technician certificates will also be awarded. (7) Logs must also show GMT date and time, band, and emission, and be received not later than September 12, 1970. The first contact for each claimed multiplier must be indicated and numbered and if possible, a check list attached. Multi-operator entires should be noted and calls of participating operators listed. Logs and comments should be sent to Englewood Amateur Radio Association, Inc., 303 Tenafly Road, Englewood, New Jersey 07631. A size 10 SASE should be included for results. (8) Stations planning active participation in New Jersey are requested to advise the EARA by August 1st of your intentions so that we may plan for full coverage from all counties.

1970 International Field Day

The Burlington Amateur Radio Club, Inc., invites you to the 1970 International Field Day to be held at the Old Lantern, Charlotte, Vermont, on Sunday, August 16. Come one day early on Saturday and join the crowd with trailer, camper, or tent. Featured will be the popular flea market, net meetings, antenna raising contest, junkbox amplifier contest, hidden transmitter hunt on 2m FM, mobile and portable rf output contest, Bingo for the ladies, door prizes, and raffle drawing. Talk-in frequencies include 3909 kHz and the .34–.94 MHz facilities of the W1KOO and W1ABI repeaters. Food, refreshments, and camping supplies available all day. Registration is $3 at the gate (or send $2.50 for early-bird to Bill Fake W1FS, 30 Southill Dr., Essex Junction, Vt.) For further information, write or call Bob Hall W1DQO, General Greene Rd., Shelburne VT 05482.

of DX competition but Eric, OH2ER, tells me he has no authorized permission to land or operate from Market Reef. Besides, OJØMR and OJØMI keep Market Reef busy.

Also note that W9FIU/KS4 at Serrana Bank were very active in the last week of February. As far as 5H3LV/ and 5HCKJ/a go they made a one day stay in Zanzibar, which should count for awards. VKØHM was put on by Hugh, WA6EAM but he wasn't on too much, probably not enough time.

TI9CF, Cocos was what many of us were waiting for.

He and all other's mentioned weren't on (as far as I know) for DX competition.

MP4QBK is another mouth watering tidbit since he was very active in mid-February from Qatar.

Wayne Green made great DXing for lots of us during his short stay in ultra-rare JY land. He operated JY1, the call of King Hussein.

Please announce a new net which meets. It is the technical discussion net meeting on 7.265 MHz and at 20:00 GMT. This net is to discuss problems with theory and rig troubles. We also discuss physical phenomena such as propagation, LDEs, etc. Net coordinator is WA1JHQ and net manager is WA1JYY.

What – No FM?

A "Ham & CB Swapfest-Picnic" is slated for Sunday, August 9, 1970, at the City Park in Levelland, Texas. Sponsored by the Northwest Texas Emergency Net and Levelland Communications Club, this is an unusual CB-Ham get-together that should prove fun for the entire family. Bring your own picnic basket. Registration begins at 9 a.m. Lunch at 1. Mobile talk-in frequency is the net frequency, 3950 kHz and channel 11 for CBers.

Publisher's Comment

Not long ago a letter came in from an irate subscriber in Europe. He complained that the magazine took a month to get to him and that it was stale by the time it arrived. This extreme sample of idiocy made me so exasperated with the human condition that I decided to try just leaving the confounded month off the cover. The material in 73 is almost all made up of articles, more like a handbook than a radio magazine, and there is little in each issue of any real time value. So what possible difference could it make to anyone whether the issues arrives in a week, a month, or two months?

Sure, we rush through articles on new developments, but most of the material could just as well be published next year or last year. This is one of the reasons that back issues of 73 have held their value so well.

Spreading the Blame

Many ex-ARRL members who have written to HQ expressing their dissatisfaction with the ARRL-sponsored incentive licensing have received replies which point out that Wayne Green W2NSD/1, editor of 73, also filed a proposal having to do with incentive licensing. This is true – I did file RM-577, but this proposal suggested rewards for obtaining the higher class licenses and did not in any way support the ARRL concept of punishing those who did not advance. RM-577 suggested the issuance of two-letter calls to Extra class licensees as an incentive, and this was accepted. It also proposed that there be separate Extra licenses for phone and CW and this was essentially enacted with the Extra phone being embodied in the reactivated Advanced class license. RM-577 proposed the opening of the following bands for SSB: 3750-3800, 14150-14200, 21.20-21.25, 28.4-28.5,

and 50.01-50.1. Unfortunately the FCC went along with the ARRL and decided to use punishment instead of reward in the matter of frequency allocations. It seems to me like a pretty cheap copout for the ARRL to now try and shift some of the blame for the catastrophe they brought on us onto someone who did everything possible to try and stop them from doing this.

One Dollar a Copy?

Perhaps you have noticed that only two of the four ham magazines appear on the newsstands. The reason for this may not be readily apparent. I won't go into the details of this problem, but the plain fact is that few, if any, magazines are able to turn a profit on their newsstand sales.

Most magazines are able to charge enough for advertising to make up for the newsstand losses, but in our field we have the advertising rates held artifically to about one fourth those of just about any other field (for comparable size magazines) by nonprofit tax-free QST. They are not on the newsstands, so they don't have to make up for these losses. The idea behind the low ad rates, I believe, is that this is supposed to keep down competition. It hasn't, but it has kept the competition struggling to try and break even with magazines that would in any other field be big money makers.

If we kept the size of 73 down to that of CQ, used cheap junky paper and printing, and made our writers whistle for their money, we probably could break even on newsstand sales. But our much larger magazine, with more articles than all the other magazines combined, fast and high payment for authors, plus everything else has kept the newsstand operation strongly in the red for the last year. The dollar price should allow us to break even, and that is considered by many businessmen today as being a runaway success.

nam (7AF) – "To be successful in this business you have to be friendly, patient, and like people," explained the noncom-in-charge at the base Military Affiliate Radio System station.

Air Force Staff Sergeant Robert L. Johnson from Henderson, N.C., handles the MARS station within the 1882d Communication Squadron. The local staff handles about 1300 phone calls per month for airmen to locations in the continental United States and the Pacific area.

"Not only do we place calls home for personnel at Phan Rang AB, we also receive calls for them from relatives and friends in the United States," stated Airman 1st Class Larry D. Orsak from Wichita Falls, Texas.

Outgoing calls fall into three categories: Red Cross priority, chaplain priority, and routine. The Red Cross and chaplain's calls usually are for emergencies and are put through as soon as possible.

"The great majority of our calls are routine, however," stressed the genial noncom, "and they usually concern promotions, base assignments, and 'R&R' which is by far the most popular subject."

When a serviceman desires to make a call to the United States, for example, he places his name on the waiting list. As soon as it comes up, the MARS operator on duty will place a call to an Air Force MARS or Civilian Affiliate station in the United States. The stateside operator in turn dials the requested telephone number.

The only expense to the serviceman is the cost of the call from the MARS station in the United States to the number which he is calling.

Unless the weather conditions are particularly bad, an airman can usually get a call through within 24 hours – often within minutes of his deciding to make the call.

"When you work in the MARS station for a little while, some pretty amusing things happen," chuckles Sqt. Thomas J. Sumpter from Covina, Calif. "Probably the funniest and most frequent mixup is when a serviceman is matched with the wrong wife, or vice versa. I remember just recently when an airman first class got his call put through to a major's wife in Kansas.

"The conversation went something like this: 'Hello, Honey, this is Bob. How are the kids?' And the answer from the states came back: 'Bob who? And *what* kids?'

While all MARS stations in Vietnam are staffed by military personnel, MARS stations in the United States are manned by both military and civilian stations. The civilian operators freely give their time and money to support the program which brings a touch of home to thousands of servicemen in lonely places around the world.

Vietnamese MARS stations play cupid, too, according to Sgt. Johnson: "We have a marriage coming up later this spring. One of our MARS operators at another base in Vietnam is getting married to a young lady in the United States via the MARS radio network. All MARS operators in Vietnam have been invited to listen in and be witnesses to this unusual marriage by ham radio."

LZ1KSZ desperately needs an i-f filter, any frequency, for his homemade SSB rig. 5 MHz ideal. If you have one to spare, please send it to 73 Magazine or direct to LZ1KSZ, Box 73, Stara Zagora, Bulgaria marked as a "free gift, used radio part, no commercial value."

WOW! Heath Twoer with push-to-talk, $40; Heath DX-60, $50; Johnson Personal Messenger, $40. All excellent. Donald Perriguey, 955 N Catalina, Pasadena CA 91104.

RBB—RBC MANUALS New, $5.00; used, $4.00; OS-8 oscilloscope manual, $3.00; some QST 1929, 30, 31, etc., Radio 1939, 40, 41, etc. Write for list. James W. Holloway W6LFL, 2027 Harton Rd., San Diego CA 92123.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

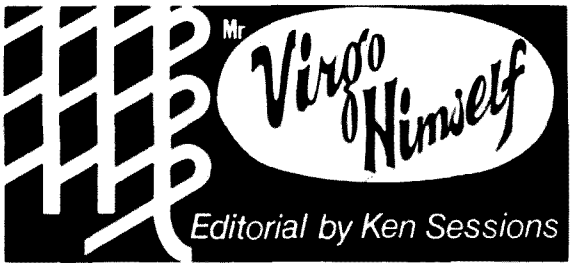
May I be so audacious as to propose a solution to a whole assortment of problems that are plaguing the FCC and amateur radio? This is consistent with my pleas for solutions rather than problems.

Problem: The FCC took away the amateur 11 meter band and opened 23 channels for business and personal use. The result was, as all of us well know, complete chaos with some 800,000 CB'ers hamming away on those poor little 23 channels. The dimensions of the problem have prevented any reasonable solution. What can be done to straighten all this out?

Problem: Virtually every newcomer to the hobby of radio gets on CB instead of going the old route of SWL and then amateur. A few manage to survive the frustrations of the CB band, but most fall by the wayside, disillusioned, and never get to ham radio. The number of new hams has been disastrously low in recent years and most of us feel that something should be done to reverse this trend. This shortage of new amateurs is already being reflected along into industry, with colleges complaining that there is a substantial drop in students interested in engineering. A cutback in amateurs must reflect itself along as an eventual shortage of engineers and technicians.

Problem: We have one amateur band that is virtually unused and which would easily be lost to us soon if this isn't changed. This is the 220–225 MHz band, which has only dozens of active users, while the 2 meter and 420–450 MHz bands have thousands. There are good reasons why this is so, but it is activity that counts, not excuses; if we don't use 220 it will go away. I think we can put it to a spectacular use.

Proposed solution: How about our having a new class of amateur license, a Hobby Class license, requiring no theory and no code, just a test of knowledge of rules and regulations? This license could permit operation within the middle four megahertz of the 220 band, from 220.5 to 224.5 MHz, thus providing two good-sized buffer bands on each end which would be regular amateur bands (providing more than enough room for the few 220'ers that are active today, as well as plenty of room for 220 crossband repeaters). With 100 watts of power, the Hobby licensees could communicate over 50–100 miles with normal beams. Further, I propose that they be limited to narrowband FM, thus eliminating heterodynes and greatly reducing QRM. I propose that they can use repeaters that repeat to or from their band, but that the repeaters must be operated by higher class amateurs.



In order to indicate the new license, I propose that a new set of calls be established starting with NA1AAA and following the other amateur radio calls in districts. When an NA (NB, etc.) moves up to a Technician or General license he would receive a counterpart call that is available (WA1AAA or WB1AAA). I propose that this program be funded by the charge of $5 for the license and that the license be valid for five years, renewable.

Such a service should provide an outlet for the hundreds of thousands (and perhaps millions) of people who want a hobby license and who have been using CB to fill this need. It should enable the FCC to move these people up to 220 and get them off the 23 channels so that these can be used as originally intended. The coming loss of skip contacts on 11 meters should help this changeover, with skip enthusiasts being able to transfer their operations to repeaters and such.

The use of FM techniques will enable millions of operators to use these frequencies without serious QRM problems. I do think that the signals should be stabilized, but that crystal control should not be required. I think that something on the order of 5 kHz deviation should be a good compromise, keeping down bandwidth, and yet giving us all the benefits of FM. With 15 kHz channel spacing this would permit an adequate number of individual channels in the band – plenty of room for nets and repeaters.

In addition to giving us super activity on 220, which is nice, we would see the rapid development of commercial gear for this band, which would benefit everyone interested in using 220. It would also help the development of 420 and even 1296 by making stabilized FM UHF equipment available at relatively low cost. The day of the $100 FM transceiver is not far off when you have a market of millions of users. Transceivers,

(continued on page 100)

The Convention Scene

Convention watchers ought to keep their eye on the Orlando Hamfest and East Coast FM Convention. This combined meeting is turning out to be one of the biggest shows in the East. Two adjacent motels (Hilton and Jamaica) were booked for the occasion, and both were filled to capacity with advance reservations.

At the Hilton, an exhibit area was set up indoors and a "swap-type" flea market was formed in the nearby parking lot. The flea market was so active on Saturday (first day of the weekend hamfest) that getting into and out of the exhibit area was difficult. The exhibit area was laid out rather poorly by Hal Shea W4BKC, who managed to resist all suggestions for improvement. Prize drawings, for example, were conducted just inside the entranceway, so that getting in or out of the building during the drawings was virtually impossible.

Also, Shea managed to string several booths into an area that doubled as a meeting place. It didn't seem to disturb him that activities in these booths conflicted with activities in the meeting area. Fortunately for the Orlando Hamfest, however, Shea's bumbling was restricted to this single level of responsibility. There were enough conscientious planners and workers to see that the convention was a success anyway.

A repeater goes up at the East Coast FM Convention in Orlando, and everybody helps. There's a lot of standing around to be done when a repeater goes up, and these fellows are doing it. Sam Carson adjusts the gain on his hip-mounted Handie-Talkie while John Perry makes preliminary checks of the repeater's coverage. The fellow grinning is Enyaw Neerg, 73's ace subscription salesman. In the background Gene Rhodes and Lou Goldstein examine the solid-state Touchtone decoders and the digital identifier to be used in the repeater when it gets permanently installed.

The FM boys from the Brevard Repeater Association put together a mobile relay station, complete with 70 ft tower, diplexer, and solid-state identifier, and installed it right at the Jamaica motel. The range was not as great as a mountaintop machine, but it certainly extended the coverage of the walkie-talkies carried by so many visiting FM'ers.

The sidebanders held a special dinner, and Wayne Green spoke briefly to the guests. After dinner, he showed a series of slides he'd taken during his recent trip to Jordan – which included photos of the American embassy taken right after the incident. (Wayne was in Jordan when it happened.) He also had some interesting views on the Arab-Israeli conflict and gave a first-hand report on the reasons for so much anti-American sentiment in Jordan.

The convention was rained out on Sunday. Like California, Florida gets fickle sometimes and provides rain when it's least wanted. The downpour all but shut down the flea market, but it seemed to have no great impact on the indoor activities. As a matter of fact, they probably benefited by the situation.

In all, the convention was an outstanding success. Hal Shea stated that some 3500 amateurs attended. Figuring a probable error factor of 50%, that brings the number to maybe 1800 – still a success by ham convention standards.

Candid Encounters

Whoever invented the ham convention deserves to be immortalized in some hall of fame somewhere. The convention, you see, is like ham radio itself – you meet people face to face, get to know them better. I can't think of a better way to demolish preformed opinions. I met Dick Cowan at a convention recently, for example. Now, to you newcomers, that name may not mean anything, but to the oldtimers, it ought to be pretty familiar. Dick Cowan is the publisher of CQ, 73's nearest competitor.

My preformed opinion of Cowan, I must admit, was negative. I had only recently read a full-scale attack on the character of Wayne Green in one of his editorials, and as a result I had decided that this was a petty, troublemaking personality whom I definitely would rather not meet. But I did meet him. And, oddly enough, I liked him. He seems nowhere near as imposing in person as he does in his vitriolic anti-Green prose.

As a matter of fact, when we got to talking, I learned that he wasn't really all that anti-Green in the first place. He said he ranked Wayne as a genius who could do more single-handedly than many magazines can with a whole staff. Back in the old days, he said, when Wayne was editor of

CQ, Cowan would tear his hair out wondering how the monthly deadlines would be met. Then, right at the last possible second, in would walk Wayne. The whole building would go into a state of siege and chaos would reign. But then, as if by magic, the whole magazine would suddenly be finished, and ready for the printer. Cowan's apparent antagonism seems to stem from the painful fact that he no longer has a Wayne Green to perform that monthly magic. Actually, Wayne should feel flattered.

It was a convention that gave me the chance to renew acquaintances with another, less threatening, competitor. At Dayton, I spent a lot of time with Skip Tenney and Jack Morgan, publisher and ad manager of Ham Radio magazine. This was a particularly interesting experience because I watched them get involved in 2 meter FM, a new mode of operation for both of them. They both returned to New Hampshire with new Varitronics radios. Their initial CQs and AM-type S-meter readings embarrassed me a little at first, but they soon got the hang of FM operation. Now they're on quite a bit, and we chat once in a while through the local repeaters. So I learned that those folks over there in Greenville really aren't all bad; as a matter of fact, they're downright lovable once you get to know them.

Conventions have other advantages, too. They expose people to new ideas. At the recent Orlando convention, I saw diehard sidebanders get converted to FM. The prospect of carrying a hand-held transceiver to a ham get-together was just too tempting for them, and they succumbed. Art Housholder, of Spectronics (Oak Park, Ill.) may have been largely responsible. He carried one of Motorola's newest dream things: a pocket-sized FM transceiver that puts out 5 watts and has a receiver that matches even the largest and best. (The price tag would scare you away, but the thing does have the power to impress you even if you aren't the impressionable type.)

I really shouldn't have said those sidebanders were "converted," because that isn't exactly true. Their interests were expanded to *include* FM, but not as a replacement for their regular bands and modes. One of the fellows, in fact, told me that he was going to get on 2m FM just so he could keep active at conventions. And he said he knew quite a few DX'ers who keep in contact with each other via FM when their regular band is hot; if one of the group spots something rare, he passes the word over the FM "intercom."

Conversion is a two-way street, too, I might add. I looked and sounded pretty ridiculous working 20m sideband when Wayne was in Jordan. Not only was I totally unfamiliar with the traditional "list" style of DXing, but I had almost forgotten how to tune in a sideband station. As it happened, I got bit by the bug, though, and now find myself sitting at Wayne's Galaxy all too frequently, working stations halfway around the globe. (Got me some good ones, too.)

ARRL Sees It Our Way

73 and QST are in almost complete agreement on the FCC's repeater proposal. In QST's June issue, the ARRL listed comments that amounted to an almost 100% replay of 73's April and May comments, a fact that should lend solidarity to the amateurs' position on Docket 18803. Briefly, here are the results:

Docket 18803 Recommendation	73 Comment	and month	QST Comment	and month
Remote activation only from fixed site	No	Feb. Apr. May	No	June
No intermediate relay for remote control	No	May	No	June
Repeater has failsafe dropout timer	Yes	May	No	June
Repeaters to be tone-coded	Yes*	Feb. Apr. May	No	June
No crossbanding of repeaters	No	May	No	June
Repeaters confined to subbands	No	May	No	June
600W limit	No	May	No	June
Repeater linking prohibited	No	Apr. May	No	June
3-minute ID	Yes	Feb. Apr. May	No	June
Logging relaxation	Yes	Feb. Apr. May	Yes	Apr. June

(* If UHF monitor is not required.)

A quick look at the chart will show that QST and 73 are in real disagreement over no more than two points: automatic dropout timers and 3-minute ID.

The automatic dropout, in 73's opinion, is a good thing. In essence, the FCC proposes to limit single transmissions to 3 minutes, with a timer to assure that the repeater drops out if the timed period is exceeded. This approach offers a built-in safeguard for repeater control when something goes wrong. The wise repeater owner already has such a system installed, because it serves the dual purpose of (1) failsafe control, and (2) discouraging longwinded ragchewers.

The other area of 73—QST conflict is the 3-minute ID rule, an unofficial FCC requirement for the past several years. The ARRL feels that identifying repeaters at 10-minute intervals is satisfactory. 73 does not.

In my early days of FM, while I was editor of FM Magazine, I had the view ARRL has today. It just seemed that 10 minutes was often enough to ID a repeater that's always in the same spot. In practice, though, I learned that I was wrong — as I'm sure the ARRL will in time. Here's why:

Many repeater QSOs do not last 10 minutes. The repeater will be "alive" for two or three minutes, dead for a few more minutes, then active again perhaps five or six minutes later. With a repeater, it's hard to know where a given QSO starts and ends, because the contacts often just run together. With a repeater ID'ing once at the start of a QSO, then every 10 minutes thereafter, experience shows that actual ID may only occur every half-hour or so with a reasonably active repeater — assuming the time is cumulative with a COR-triggered timer. The only alternative is to have the repeater identify itself whether it is being keyed or not, and there aren't too many repeater boys who want that.

The FCC has learned that IDs are far too few and far between if a 10-minute elapsed-time indicator is used. But with a 3-minute timer operated from the COR, actual identification takes place approximately every 6 minutes while the repeater is in use. This disparity exists because most repeater timers are COR-operated. The timer comes on when a carrier appears, and stops timing when the carrier drops out. No time is logged during the repeater's "extended carrier" operation or during the "squelch tail" and "space" periods between transmissions. Thus, it takes anywhere from 6 to 8 minutes of normal operation to log up 3 minutes of actual use.

If you wonder why cumulative COR timers are so much more practical than simple elapsed-time indicators, just ask the repeater owners. There are plenty of reasons; they're complicated, to be sure, but very valid.

. . . K6MVH

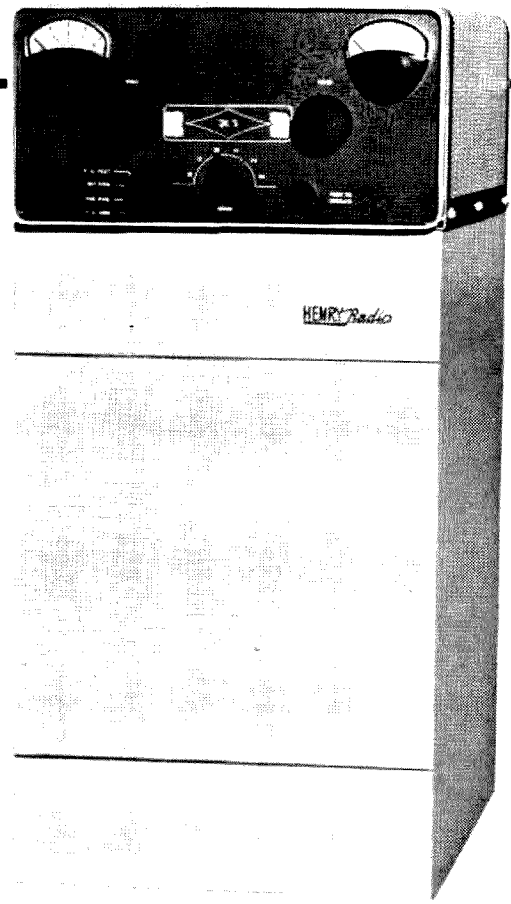
May I entreat you to call upon your best qualities; forbearance, objectivity, maturity, understanding, and tolerance, before you read what I have to say in this editorial? There is a serious and profoundly important issue at stake, and while this is not going to be any sort of statement of my own personal views concerning the substantive questions involved, there is a tangential point which merits examination. In other words, the matter at the heart of this issue, namely the world political situation, is not in question here. I wish to discuss another phase which bears upon it merely as a corollary.

On Saturday, May 9th, on a frequency of 14.292 MHz, a net was organized. It consisted of college club stations and others, and was supposed to be operating for the express purpose of exchanging information with respect to the student demonstration which took place in Washington on that day. Periodically, between these exchanges, and in anticipation, perhaps, of a not unwarranted negative reaction on the part of the casual audience on the frequency, announcements were made, stating that the net was intended to be nonpolitical, and nonexpressive with respect to any views on the war, campus disorders, the Administration, or any such things, but was merely seeking to implement the logistics of the Washington demonstration . . . moving the people, rotating buses, providing emergency medical attention for the ill, etc. There was, however, as it turned out, some propagandizing and political drum-beating, which obviously was inevitable.

On the air, many persons have expressed horror and revulsion at the idea of our ham bands being used for such a purpose. Wholesale comment has been noted, during which some have suggested that the licenses of participants ought to be suspended or revoked altogether. Some have gone even further, and have demanded imprisonment, the imposition of heavy fines, and even loss of citizenship! And a few outspoken intemperates have gone so far as to suggest that all such persons ought to be "stood up against a wall and shot!"

Now, this question is not one to be discussed in an atmosphere of fearful hush-hush or careless facetiousness, for it is a deadly serious matter, demanding sober and prudent coolheadedness. The central core of the question is not whether it is right or wrong to dissent privately from the mainstream opinions held by the majority. The question of the right to hold private opinions has nothing to do with this, for that particular issue was settled long, long ago. I am sure that most of us can and do agree that everyone is entitled to his own opinion.

The core of the matter is whether persons who do dissent shall be allowed to air their ideas on our radio spectrum, which has always been confined to a rather limited range of allowable topics. And, if they are allowed to extend the range of discussion to include some form of dissent, just how far may they go? Must they be restricted to small controversies, or can they open up the whole can of beans . . .let out all the stops . . .and really get to digging into the "gut" issues?



Dissenters are utilizing the campuses, and many of us object to this, regarding it as inordinate license and abuse of privilege. They are using the public streets and squares, and we object to this also. But how about the ham bands? Just where is the point beyond which amateurs may not conduct such activities, or, more specifically, is there such a point? Or, if there is not, ought there to be such a point?

Should the bands be preserved as a sort of ivory-towered vacuum, removed from life and all its ramifications? Should hams be restricted to subjects which are divorced from all vestige of germane relationship to our times and our conditions? Must they avoid visceral issues, and be Pollyannas?

The issuance of a license by the FCC constitutes a grant of privilege. Is this grant limited, carrying an implicit power of censorship, cutting off the ordinary provisions of the First Amendment of the Bill of Rights? Does the holding of a license constitute acceptance on the part of the licensee of a set of behavioral standards, somehow at variance with those which pertain to the rest of the citizenry? In other words, when you take a ham ticket, are you agreeing to waive a significant section of your constitutional rights as an American citizen in good standing?

Are hams, in fact, under an obligation of some sort which compels them to avoid the controversial in all their contacts on the air? Before you reach for any glib or easy answers to these questions, remember just one thing: It has

the 2K-3

. . . Beware of cheap imitations

Sure you can buy a linear amplifier for less money . . . but will you really save? We believe the 2K-3 is the finest all around amplifier ever designed for the amateur service. And it is a unique value because of the superlative quality components it contains. The 2K-3 is built to perform at peak efficiency year after year after year. And, you'll never have to "trade-up", you will already own the best. Before you buy any linear compare them carefully, look under the hood. You may find some similarities, but no equals. One competitor's complete unit, for example, weighs little more than the 2K-3's power transformer alone. (that's only one of the many important differences) If you want the best . . . it has to be the 2K-3

EASY FINANCING • 10% DOWN OR TRADE-IN DOWN • NO FINANCE CHARGE IF PAID IN 90 DAYS • GOOD RECONDITIONED EQUIPMENT • Nearly all makes and models. Our reconditioned equipment carries a 15 day trial, 90 day warranty and may be traded back within 90 days for full credit toward the purchase of NEW equipment. Write for bulletin. Export inquiries invited.

never been considered wrong for hams of the opposite persuasion to display at times the most outspoken advocacy of violence imaginable, just so long as it had not been against what is generally referred to as the Establishment. No one seems to take issue with a man who wants to restore capital punishment, to impeach the Chief Justice of the United States, to send all Black persons back to Africa, or to drop a hydrogen bomb on Moscow or Peking. But just once, let someone express some idea which appears to run against the Establishment line politically, and that's when the fur begins to fly. So when you search inside yourself for answers to these dilemmas, I urge you to try to be perfectly fair and objective about it.

Once, at a Veterans' Day Parade on Fifth Avenue, a female spectator shoved a man standing in front of her, because he failed to doff his hat as Old Glory went by. As he fell flat on his face in the gutter, she cursed at him vehemently, calling him a communist SOB. When some less acrimonious persons helped him to his feet, it was seen for the first time that he could not very well remove his hat, since he had no arms! He was wearing a Purple Heart rosette in his lapel, and was also wearing a VFW insignia. This double amputee had sacrificed his limbs in the service of his country, while protecting the life and security of the very one who had pushed and villified him!

All of us have had occasion to observe the excessive zeal of superpatriotic fanatics, who desire every American to conform in dress, haircut, opinion, life-style, religious piety, politics, and so forth. Sometimes the figuratively armless and legless among us must contrive to prove every single day of their lives that they have earned their right to individuality. Yet, that is precisely the cause for which their sacrifices have been made. There is always some zealot, ready and eager to push them down into some gutter, when they fail to salute the flag, don't wear a red "buddy poppy," or don't care to have their kids join the Little League. Among certain people, the very worst transgression of all is the refusal to conform.

When will we learn to recognize the difference between patriotism and blind conformity to convention? There is a vast gulf between the two, yet the line of demarcation is becoming increasingly harder to discern. There really is not much of a generation gap to speak of, so much as there is an adamant refusal to tolerate the next fellow's point of view. Once we can overcome this intolerance, the schisms will be minimal.

In one of these pieces, some time ago, I stated that free speech was very much like pregnancy . . .there's no such thing as a little of it. You either have got it, or you haven't got it. And once you interfere with its progress, or try to limit it in any way, it is destroyed completely.

Now, please bear in mind that all of this has absolutely nothing to do with acts of violence. . . incendiary fires, bombings, stoning the police, unlawful occupation of buildings, destruction of private property, flinging of ordure on the heads of persons in the streets below, looting, burning of draft cards in violation of the law, and so forth. Where such violence occurs, free speech no longer exists. The very idea of free speech. . .its heart and soul. . .exists in the fact that *both* sides of a dialog should have the right to express themselves. Where only one side has the floor, freedom of speech is a mockery. And the majority is not necessarily compelled to grant free speech to the minority, while it gives up its own right to the same privilege. Many persons who wish to be granted all democratic rights because they are expressing minority points of view think that the majority should be silenced. This is just as distorted as the other side of the coin.

Anyone who commits acts of violence, no matter what position he takes on the issue, should be tried, and if convicted, put into confinement. The idea that wrongdoers should be treated permissively on the grounds that they will develop complexes if they are held accountable, is one of the worst causes of violent behavior in our society. We simply cannot afford to allow malefactors to get away with some of these atrocities they commit in the name of Constitutional Rights.

The difference between freedom and license is clearly definable, and society cannot afford to allow the latter to devour and destroy the former!

This nation of ours, almost two hundred years old, can easily endure all the verbal attacks of the dissenters. It can stand all the mealy-mouthed vituperation, the arrant nonsense, the short-sighted ravings of Utopians who propound the false syllogisms of misbegotten political creeds. But this nation cannot survive the rigid, sanctimonious ignoramuses, who, in the name of blind patriotism and conformity, arrogantly demand that everybody must think, talk, and act as *they* do.

No country which demands of its people that they vote 'Ja,' can hope to endure, for such demands grow out of an all-consuming fear. And such fear grows out of a lack of faith in the system, the political institutions, and worst of all, out of a country's failure or unwillingness to recognize and respect the rights of its individual citizens.

God help us on the day when anyone in America, whether of the majority or minority, is muzzled, and cannot freely express his opinions. We have a splendid, unparalleled legacy here, of both liberty and the courage to preserve it. Let us repudiate those fears which tempt us to limit our liberties.

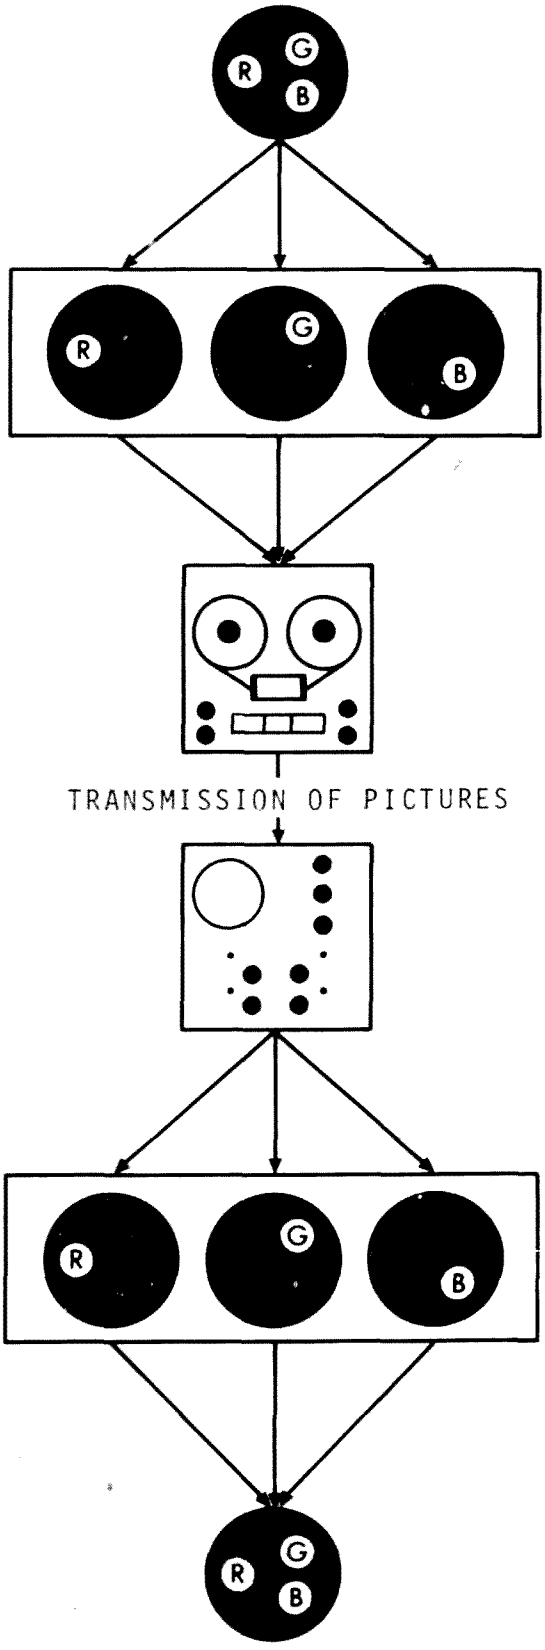
AN IMPROVED METHOD FOR THE TRANSMISSION OF COLOR INFORMATION BY SLOW-SCAN TELEVISION

Photograph of televising process.

Theodore J. Cohen W4UMF
6631 Wakefield Drive, Apt. 402
Alexandria VA 22307

Wade L. Tarr
143 Bryan Drive
Sarver PA 16055



In a recent article (73, Jan. 1970) we described a method for transmitting a color picture by slow-scan television. The method essentially was one of performing a tricolor analysis of the color picture, transmitting the resulting black-and-white separation pictures by slow-scan television, and reconstituting the original color picture using a separable, subtractive synthesis process (Color-Key). The separable synthesis process used had many advantages, including a relaxed registration requirement (small deviations in the size and orientation of the separation pictures can, with care, be corrected in the synthesis process) and a capability for controlled color correction in the fabrication of the reconstituted picture. The method, however, does suffer one major drawback: too many photographic steps are required in the synthesis phase. The method we now describe contains at most two photographic steps. As these steps can involve the use of Polaroid film, it is now possible to produce, both quickly and economically, a good reproduction of a color picture transmitted by slow-scan television.

Method

The improved method proposed for analyzing and synthesizing a color picture is shown in Fig. 1.

The subject – here a set of red, green, and blue circles on a black background – is photographed three times, once each time through a red, a green, and a blue filter. The three black-and-white separation pictures (positives) so produced are then televised and tape recorded; transmission of the taped pictures proceeds via high-frequency SSB, the telephone, or the mail. Upon receipt, the separation pictures are displayed on an SSTV monitor, and three successive time-exposures of the separation pictures are photographed *on a single color film frame* through corresponding red, green, and blue filters. When this film is developed, a reproduction of the original color subject should result.

Basic to this method of color analysis and synthesis is a strict registration requirement. As the actual color synthesis is done *within the camera containing the color film*, correction of magnification or positional differences in the separation pictures is, for all practical purposes,

ORIGINAL COLOR SUBJECT

PHOTOGRAPH COLOR SUBJECT THROUGH RED, GREEN, AND BLUE FILTERS. SEPARATION PICTURES MUST BE IN REGISTER.

TELEVISE, IN REGISTER, THE BLACK AND WHITE SEPARATION PICTURES; TAPE ON CONVENTIONAL AUDIO TAPE RECORDER.

DISPLAY, IN REGISTER, THE BLACK AND WHITE SSTV SEPARATION PICTURES

TAKE THREE SUCCESSIVE TIME EXPOSURES THRU RED, GREEN, AND BLUE FILTERS. ALL THREE EXPOSURES MADE ON ONE COLOR FILM FRAME.

SYNTHESIZED COLOR PICTURE

Fig. 1. Improved method for transmission of color information.

impossible. Thus, in the analysis phase, it is absolutely necessary that the three black-and-white pictures be photographed and televised in register. In synthesizing the color reproduction, no relative movement between the SSTV monitor and the film camera, or changes in the scanning dimensions, can be tolerated.

The method described here is similar to that investigated by Davies (1964) for use in the Surveyor moon-probe program. In working with color film processes, Davies employed both Polaroid Polacolor and Kodak Ektachrome film. Objections raised by Davies to the use of these films were:

1) Polacolor film lacked dynamic range.
2) Photographs had a blue cast resulting from the blue hue of the monitor screen.

The latter fault is somewhat negated by the use of P7 phospors (blue-green) in SSTV monitor screens. Should additional hue correction be required, however, variations in f/stop settings and filter densities can be instituted in the final photographic step. It should also be noted that in the developing process for Polacolor film, a shorter developing time will bias the print towards the red end of the spectrum. In printing pictures from films such as Ektachrome the use of color-correction filters is common practice.

Lack of dynamic range in Polacolor film is not so great as to deter use of this film in amateur SSTV work.

Color Analysis

The method described was tested using the picture shown in Fig. 2. To aid in the synthesis process, red, green, blue, light gray, and black chips were mounted beneath the picture; accurate reproduction of the color chips assured proper rendition of the main color subject. The subject card was photographed through the necessary filters with a Polaroid Model 110B camera. Type 47 Polaroid black-and-white film (ASA 3000) was used and a closeup lens was attached to the camera. Filters used were: red (Wratten 25A), green (Wratten 58B), and blue (Wratten 47). The subject picture was indirectly illuminated by four 300W photoflood lamps. Every precaution

Fig. 2. Color subject. Photo courtesy VARIG Airline.

was taken to insure the three separation pictures remained in absolute register – that is, that the camera did not move between exposures.

The three black-and-white separation pictures resulting from the analysis process were carefully aligned and mounted on a keyed cardboard backing. In the televising process, this keyed backing was shifted relative to a fixed piece of keyed cardboard, insuring proper alignment of each picture in front of the SSTV camera (Fig. 3). The three separation pictures, televised in register, were recorded at 3-3/4 ips on standard 1-mil Mylar audio tape.

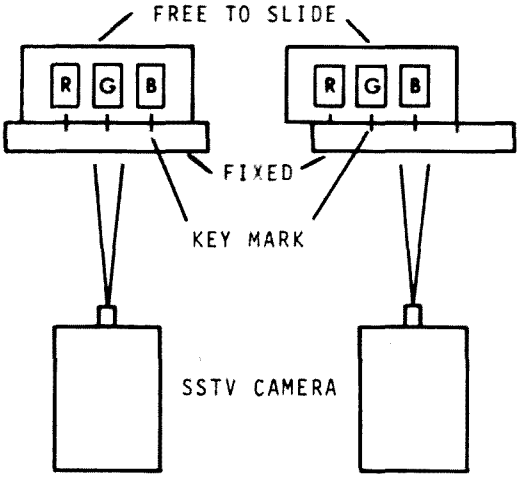


Fig. 3. Alignment method used in televising process.

It is possible, with some SSTV imaging systems, to do direct color separation with the SSTV camera. Slow-scan systems employing 931A photomultiplier tubes (Hutton, 1968) or conventional vidicons such as the 6326 (Taggart, 1968; Hutton, 1969) have spectral response functions suitable for use in direct color separation (Cohen and Tarr; 73, Jan. 1970). Slow-scan vidicon tubes, however, peak in the blue-violet, and cameras employing these tubes (Macdonald, 1965) can not be used for direct color analysis. As a camera employing a WL-7290 vidicon was used in the present work, it was necessary to perform the color separation by photographic means.

Color Synthesis

The separation pictures were displayed on a 3 in. hybrid monitor employing a 3RP7A cathode-ray tube (CRT). The Polaroid 110B camera, now loaded with type 48 Polacolor film (ASA 75), was rigidly fixed in front of the monitor. To minimize relative camera-monitor movement, the camera shutter was not used, and a black card placed before the lens between exposures. All work was done in a completely darkened room. No changes in monitor control settings were made between a given set of time exposures. Some experimentation with exposure time was necessary to produce an acceptable Polacolor print. The direction such experimentation took was influenced by careful analysis of preceding exposures. For the type CRT and film used, we found it necessary to photograph 8 frames of each separation picture, through its respective filter, at an f/stop setting of 4.7. The room temperature, 75°F, dictated a developing time of 60 seconds.

Results & Conclusions

We have demonstrated a method for quickly and economically analyzing and synthesizing a color picture. At most, two photographic steps are required, both of which can involve the use of Polaroid quick-processing film. Careful attention must be given to insure registration of the black-and-white separation prints. However, by exercising care, amateurs should now be able to use this method to transmit color information by slow-scan television.

Fig. 4. Synthesized color subject.

The synthesis of the color subject is shown in Fig. 4. This picture was obtained on the third try. To the extent that the color in the reconstructed picture matches the color of the original subject and the color chips, we classify the picture quality as "good."

FOR EMERGENCIES: THE SUPER

by Ken Sessions, Jr. K6MVH

When disaster strikes, there's no substitute for thorough, effective, versatile, and handy communications capability. Nothing gives these features quite so impressively as an autopatch. This one is ideal because it does everything – even lets you answer the phone, on command, without tones. Perfect for public service and emergency use, where phone access from hand-held units is desirable.

The most useful single commodity there is when an emergency occurs is communications capability. Not just any communications capability, though; to be useful in an emergency, a communications network must be readily accessible by officials and it must be capable of giving two-way coverage to and from any other single point in the country. Not ham radio, you say? You think the telephone is the only qualifying form of communications here?

Wrong and right, in that order! No one could deny the value of an unencumbered telephone line at the scene of a disaster. A phone can give almost instant two-way communications between any two points at will. Further, those people who *need* to communicate with the "outside world" in an emergency situation are accustomed to using a telephone – they feel more at home, more sure of the results – they'll be less confused at a time when confusion reigns. But of course it is impossible to

AUTOPATCH

Disasters are not respecters of property. When Hurricane Diane hit the town of Putnam, Connecticut, the power and phone lines went, too. The hurricane also brought torrential rains that caused New England rivers to flood many cities and towns along their paths. The only form of communications in such emergencies is the mobile or portable radio units; and these can provide the phone coverage ravaged by nature. (Photo by Motorola News Bureau.)

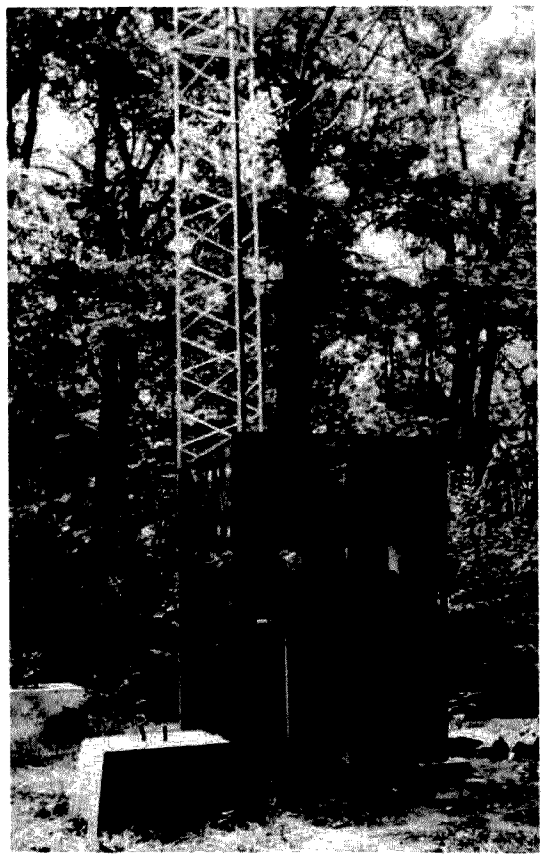
arrange for a telephone line to be ready and waiting at the site of the next disaster.

So let's take a look at what we've always considered to be the next-best thing: a ham radio traffic network. On the plus side, such a net can give the officials what they need most: a means for communicating. But a negative aspect is the fact that the choice of places where direct two-way communications can be maintained is restricted to places where amateurs are stationed. And communications effectiveness is hampered to a certain extent by the officials' inherent unfamiliarity with a ham radio setup. We've all seen the official who wants to talk to his contact while the contact himself is transmitting. Ham radio simply takes some getting used to.

The modern ham can, however, offer a disaster communications system that offers all the advantages of a conventional telephone, plus the capability of working into and through an organized message network. The secret is operating a simple autopatch in conjunction with an existing FM repeater.

Use of an autopatch offers a number of advantages that even Ma Bell can't match. For example, the official who wants to initiate a telephone call need not leave the area where he is needed in order to find a telephone. He can access the repeater autopatch through a hand-held walkie-talkie or from the amateur's car. (If the autopatch is built around a UHF repeater, say the control facility for a 2 meter

repeater, the official should feel particularly at home, for he won't be able to tell the autopatch from a regular telephone – he'll be able to dial directly, enjoy full duplex, etc.)



One of the most obvious disadvantages of a landline in an emergency is that *there may be no landline after the disaster strikes*. A flood could wash away the phone poles. A jet crash might take out all the lines in the vicinity of the site. Disasters of all kinds – fire, tornado, hurricane, earthquake – all have a habit of wiping out the telephone service in the vicinity of where the phone is needed most. But with an autopatch, the phone line may be far removed from the disaster scene. The chances of a landline outage at the repeater site occurring simultaneously with a disaster somewhere else are slim indeed.

One thing is certain. Bring a telephone to the site of a disaster and you'll be one welcome fellow. If you are already operating through a repeater that has public service ties, those ties will be strengthened immeasurably by adding telephone capability.

There is no guarantee, of course, that operating a telephone-interconnected repeater from a portable or mobile installation will be legal after the FCC gets through fiddling with repeater rules. But even the FCC would have to agree that an autopatch is certainly in the best interest of the public, which is what ham radio is all about when you get right down to the basics of the issue. A sensible approach, then, would be to proceed with plans for increasing the usefulness of your system, having faith that the Fed will not tighten the vise later.

Legality of Radio/Telephone Autopatch

A great many amateurs seem to think it is illegal to interconnect a telephone with a repeater for automatic patching. As my own remote control license will attest, this is simply not true. The legality of a remotely operated telephone system depends on its ability to meet the requirements of FCC Rules and Regulations. The principal requirement is that incoming calls must not be capable of keying the transmitter when no licensed operator is monitoring from the control point.

Most autopatches are simply phone patch panels installed at a remote repeater site where telephone service is available. Often, owners of commercial remote installations such as the one pictured here will permit amateurs to install an autopatch-equipped repeater. The key word is service, and no facility fills the bill more perfectly than a ham repeater whose users are prepared to act fast in an emergency. (Photo by Motorola News Bureau.)

Another area of questionable legality is that of controlling a remote station from a mobile unit. The FCC says that a remote station must be controlled from a fixed site. To many, this automatically precludes the possibility of setting up a control station in the mobile. But close scrutiny of Part 97.43 of the Rules reveals no prohibition of mobile control. The currently popular interpretation of the Rules is that control can be accomplished from anywhere as long as fixed control is maintained.

Some amateurs even go further, and do not maintain a fixed control *per se*. They say they get their authority to control exclusively from a vehicle because of the

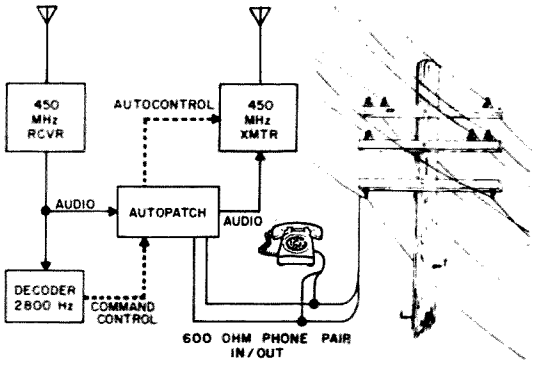


Fig. 1. The autopatch's interconnection with the phone line has no effect at all on an existing telephone connection since it is wired in parallel with the instrument. The block diagram shows how a fully duplexed autopatch system is set up with a UHF repeater.

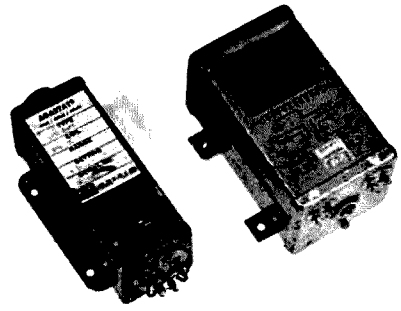
permission to do so given by the conditions on the back of the amateur license. According to the statement on the reverse of General and Technician class licenses, the remote control point is considered "fixed" even though it may be actually mobile or portable. (Take a good look at the back of your license; it pays to read the small print.)

Not all individual officers of the FCC go along with wording on the back of the license, I hasten to add. James Barr, for example, who happens to be an FCC wheel, says the control station must be fixed – the disclaimer on the license notwithstanding. But Barr might have a rough time making his opinion stick when the official documentation plainly counters it.

In spite of all those hair-splittings, no one within the FCC has ever been known to deny the legality of mobile control *as long as a licensed fixed station is manned by an operator authorized to turn the remote system off should the need arise.* (Docket 18803 would change this, however, if it goes through.) And even Barr has gone on record as endorsing *subcontrol* (which is what exists when a mobile operator controls a remote station that is capable of being controlled by an overriding authorized control station).



Understanding the Telephone

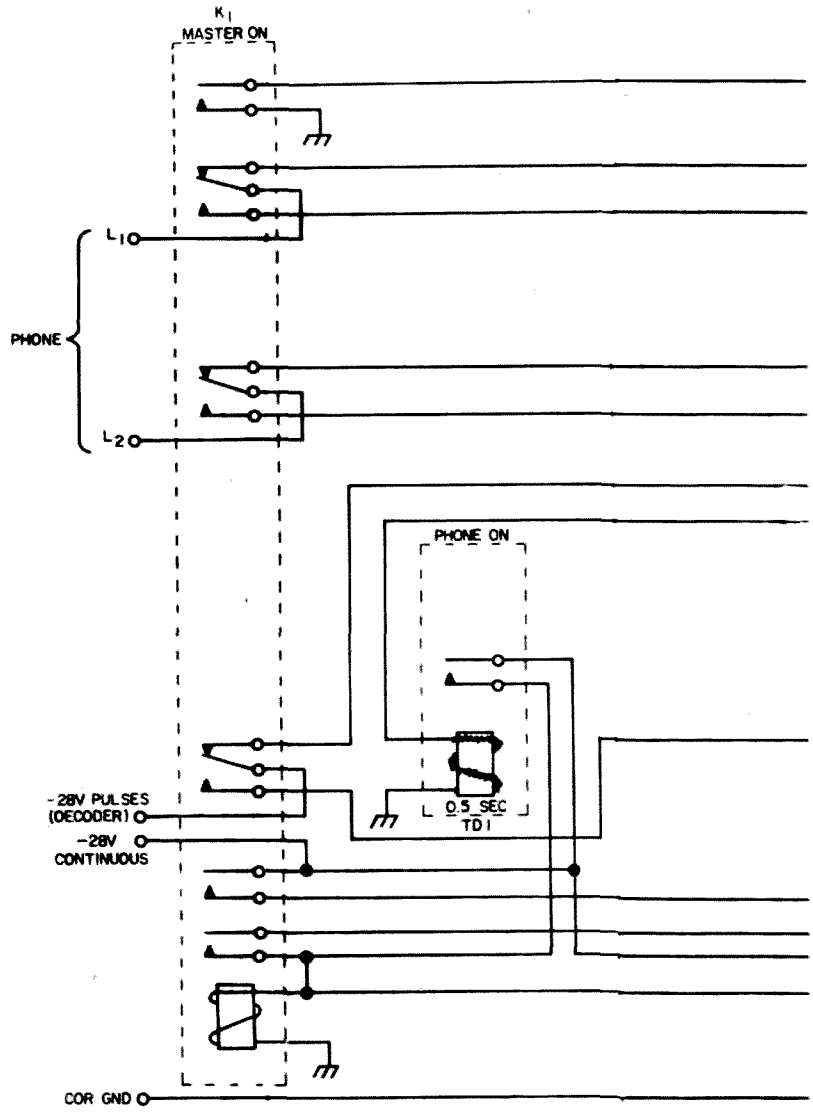
The conventional telephone uses but two wires to accomplish what may amount to a multitude of different functions. There is typically a low voltage dc level across the line to drive the carbon microphone element. When the telephone rings, however, a higher voltage ac signal is superimposed on the line pair to energize the bell in the instrument.

A telephone with its receiver on the hook is an open circuit. The circuit closes when the receiver is lifted, introducing a moderately low-resistance load (several hundred ohms). The dial is a rather complex switch device that has the capability of opening the circuit briefly for a number of times that correspond to the number dialed. The circuit stays closed as the finger hole is brought around to the stop. Then, circuit "opens" are pulsed out sequentially as the dial returns to its "home" position. Thus, the dialing function could be simulated by rapid manipulation of the hang-up button, provided that the required speed of 10 switching operations per second could be maintained manually. And hang-up could be effected (temporarily) by controlled positioning of the dial.

The "Super" Autopatch

The block diagram of Fig. 1 shows the method by which an automatic patch such as the one described in this article is interconnected into a UHF repeater. The broken lines represent control signals and the solid connecting lines represent audio signals. As can be seen, the telephone needs no modification, and is interconnected with the system by merely tapping into the two wires that are already part of the

Agastat pneumatic timers are perfect for autopatch applications because they can switch plenty of current, they are instantly resettable, and they offer a high degree of reliability. The unit at left is a standard adjustable time delay relay (TD1, TD2, TD3 in schematic of Fig. 2); at right is a delayed dropout. Units are available surplus for $3 to $5 each.



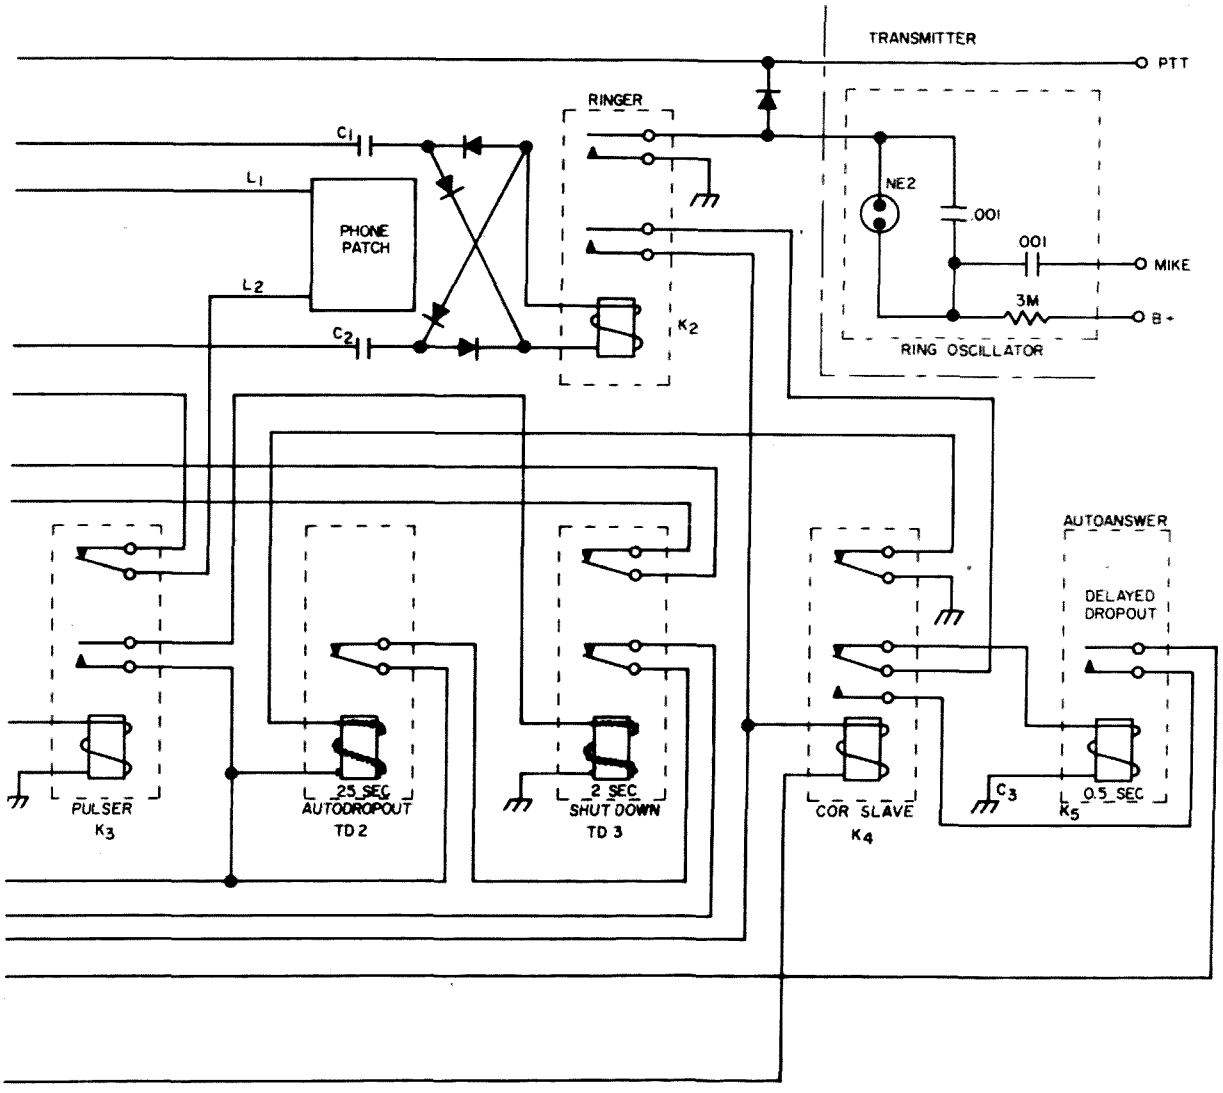


Fig. 2. This autopatch circuit has everything: timed on, timed off, autoanswer from units that are not tone equipped, and a number of built-in "failsafe" features to assure control even if you lose control.

existing telephone circuit. It should be noted that the autopatch can be integrated just as easily into a 2m repeater, though duplex operation would be next to impossible to achieve for the user mobiles because of frequency proximity and attenuation problems.

The autopatch itself performs the magic. Shown in Fig. 2, the circuit contains all the elements necessary to make it the "cadillac" of automatic patching devices. It does just about everything. In response to timed control tones transmitted by the control operator, it can "lift the receiver from the hook" and interconnect the phone patch with the repeater; or it can "replace the phone on the hook" and disengage the repeater. When the phone rings, the control operator knows he has an incoming call: the autopatch generates its own tone and turns on the repeater transmitter with each ring.

Without the need for tones, the control operator has the capability of allowing the phone patch to be engaged or not, as determined by the sequence by which he activates the carrier of the control point transmitter. And, as a final safety measure, the autopatch disengages from the repeater when there is no control signal immediately apparent. If, after the control operator engages the phone patch, he loses control or his transmitter drops off the air, the patch disengages itself in seconds, shutting off the repeater transmitter until control can be reestablished.

Ring Indication. Since the autopatch is likely to be incorporated into an already existing repeater setup, the circuit has been designed for full compatibility. The phone

line at the repeater site can be continuously monitored for incoming landline calls without disrupting the normal operation and control functions of the repeater. During normal repeater use, the phone line is sensed for the presence of an ac voltage (which would indicate that the phone is ringing). The two lines of the twisted pair are fed through a set of normally closed contacts on the main relay (K1) to a bridge rectifier circuit. The dc component of the line is isolated by placing 0.5 μF capacitors in series with the conductors. A sensitive plate relay on the output of the bridge pulls in when the telephone rings and keys the repeater transmitter for the duration of the ring. This momentary closure of the relay triggers a signaling device so that when the transmitter is thus keyed, a ring signal is generated also.

The ringer shown in the upper right corner of Fig. 2 is nothing more than a simple relaxation oscillator; it can be constructed in a few minutes with a couple of capacitors, a resistor, and a neon lamp. The device shown generates an unstable tone that is easily identifiable at the receiving end.

Timer Considerations. The "super autopatch" makes extensive use of timers for effective active and passive control. The timers used in my own autopatch are Agastat pneumatic delay devices made by Elastic Stop Nut Corporation (ESNA), of Elizabeth, N. J. If purchased new, these delays can be quite expensive. I bought mine at a bargain price of $1.50 each from "Pappy" Dow, a Southern California surplus mogul.

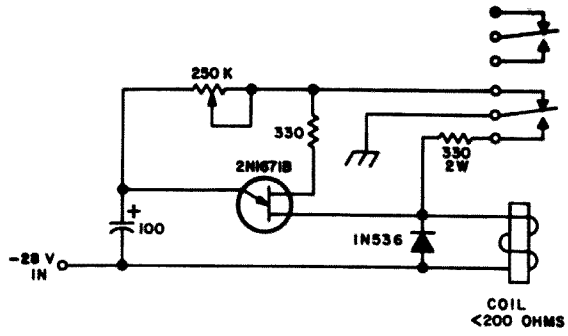

Fig. 3. This unijunction timer circuit offers a broad range of delay periods, from less than 0.5 second to more than 3 minutes. The delay is set by the 250 kΩ pot; each 10 kΩ of resistance gives a second or so of delay. In practice, of course, the pot would be replaced by the proper fixed resistor, because there would be no need for a variable time delay.

All-transistor timing and switching circuits work quite well, but their incorporation does make the schematic a bit more complicated because of the various polarity requirements. The cheapest way to miniaturize would be to compromise a bit by using hybrid timer circuits that employ miniature relays for switching in combination with unijunction timer circuits.

Figure 3 is an adaptation of a timer circuit that was published in GE's "Transistor Manual, Seventh Edition." This circuit is particularly versatile because it employs a low-cost semiconductor, relatively few parts, and an easy-to-find relay with a coil resistance of 150–200Ω.

The Phone Patch. The phone patch itself is an item that warrants some attention, but a great deal has been written on this subject in the past so I won't go into it in detail here. As references, I will cite the FM Repeater Handbook (Editors and Engineers, Ltd., Indianapolis, Indiana), FM Magazine (July 1968 and December 1968), FM Anthology, Volume II (73 Bookshop), and 73 Magazine ("VHF Operation by Remote Control," August 1968).

The most important point to remember when connecting a phone patch into an autopatch system is to leave a dc path through the patch primary. If a series capacitor is placed in the circuit, it should be shorted; otherwise telephone ringing and dialing cannot be effected automatically for remote operation.

"Desirable" characteristics for commercial phone patches are: (1) a high degree of signal isolation, (2) automatic compression circuitry, and (3) built-in preamplification for phone signals.

Autopatch Decoder Control

In the system described here, a high-frequency tone decoder is used to switch a −28V signal for control of the autopatch when a call is to be initiated. The decoder shown in Fig. 4 is ideal for this purpose, having stood the test of time and use. This unit, by the way, is a simplified version of Motorola's transistorized decoder (Part 9-SP022563), which is itself available from Spectronics, 1009 Garfield, Oak Park IL, for $40 postpaid.

The original Motorola circuit is not satisfactory for dial pulsing because it is slow-responding. The Motorola version is used as a "single-tone" controller, where a stable, continuous tone is needed. Removal of a few circuit elements, however, makes the Motorola decoder a natural for phone pulsing applications. (The circuit of Fig. 4 is a quick-pulsing decoder that responds easily to tone pulses of a 10 per second repetition rate.)

Tone Frequency. The decoder is set to respond to tone signals in the frequency range of 2200 to 2900 Hz. Adjustment of the frequency-sensitive elements permits the pinpointing of any 50–75 Hz bandwidth within that range.

Of course, any frequency between 600 and 3000 Hz can be used, but the lower frequencies have serious disadvantages in practical applications. At frequencies between 600 and 1000 Hz, for example, ordinary conversation causes decoder triggering, and the result is errant and inadvertent operation of the functions to be controlled. Frequencies from 1 to 1.5 kHz can also be triggered by occasional voice signals; and a playful repeater user can toy with the phone by simply whistling.

Things begin to get more secure as the frequency goes up. But at 3 kHz, the audio processing capability of the transmitting and receiving equipment may be exceeded, particularly if there is inherent audio distortion in the system. The range from 2.25 to 2.85 kHz should prove ideal: It's difficult to voice-trip, it resists whistle-on

attempts, and it is well within the frequency-response limits of most commercial FM units.

Decoder Alignment. Since impedances are critical when making voltage measurements at the decoder input terminals, an electronic ac voltmeter (vtvm) will be required. With the voltmeter connected across the receiver's audio output leads, have one of the repeater users transmit a tone. With the tone on the incoming signal, adjust the 500Ω pot on the decoder input for a reading of 400 mV. If this is not obtainable, set the 500Ω pot to midposition and adjust the receiver audio gain control. (If the receiver "speaker" audio connects directly to the transmitter, repeater levels will have to be readjusted.)

Next, connect the voltmeter (ac range) from the wiper arm of the 500Ω pot to point A of the 50–100 mH inductor, then adjust the inductor for a peak indication on the meter.

Move the voltmeter lead at point A to the cathode of diode D1 (point B), then *slightly* adjust the 50–100 mH inductor for a *dip* indication.

Autopatch Operation

In operation, when the ham operator sends a note of the proper frequency from the remote control point, the decoder switch closes, applying a –28V signal to the phone patch "master on" relay (K1). Look now at Fig. 2, to see where the –28V decoder-pulse terminal is on the autopatch unit. During the time the operator sends a tone, the negative-voltage signal is applied through the normally closed contacts of K1 and the normally closed contacts of shutdown timer TD3 to the coil of "phone on" timer TD1. At the end of the period of TD1, exactly one-half second, the coil energizes to supply power to the coil of the "master on" relay, which latches in the energized position.

When K1 is latched on, the phone patch is in the circuit and the decoder output is connected to pulser K3. If the operator's tone generator is connected to a telephone dial so that tone pulses can be transmitted, K3 can be used to dial any number. Pulser K3 interrupts the dc circuit of the phone line to accomplish this. At the end of the phone conversation, transmittal by the operator of a continuous tone will hold pulser K3 in. A second set of contacts on K3 feeds the coil of a shutdown timer, which will pull in after a 2-second period to completely disengage the autopatch.

Malfunction Protection. An autopatch is a borderline thing with a respect to official sanctions; it thus behooves the builder to take every precaution possible to see that failsafe measures of every kind are included. The schematic of the autopatch shown here includes a feature that shuts down the patch if the remote operator does not transmit at least one brief signal

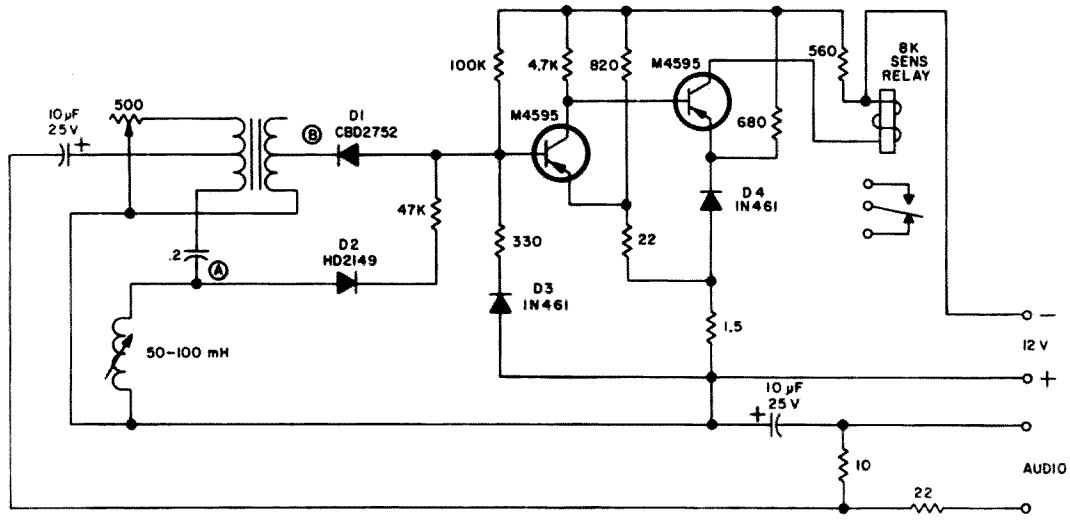

Fig. 4. This audio decoder responds to signals in the frequency range of 2200–2900 Hz. Precise setting is explained in the text. Although Motorola part numbers are shown, equivalent values may be substituted.

every 25 seconds or less. If more than 25 seconds goes by without an incoming radio signal, the shutdown timer (TD3), supplied through the normally closed contacts of the carrier-operated relay, will break the circuit supplying the latching voltage to the "master on" relay.

Most repeaters already are equipped with timers that shut down the repeater if a signal stays on too long, so none was included in this patch. The two schemes are perfectly compatible, and they do complement each other in such a way that when an operator cannot demonstrate that he has control, the phone patch will turn itself off automatically. To effectively demonstrate control, the operator must not talk – during any single transmission – longer than the safety timer of the repeater, and he must transmit a signal at intervals of 25 seconds or less.

Control Without Tones. To answer the phone quickly when it is ringing, the operator can engage the phone patch with the tone as described earlier. Or he can do it, without tones, by transmitting a carrier at a precise time. If he transmits the carrier too soon or too late, the phone will keep on ringing and will not be answered. The autoanswer feature is performed with ringer K2, the COR slave (K4), and autoanswer relay K5 (a delayed dropout relay with a period of 0.5 second).

When the phone rings, ringer K2 energizes only during the period of the ring. The closed contacts of K2 during the ring apply a –28V signal to the delayed dropout relay (K5) through the normally closed contacts of the carrier-operated relay. Thus, K5 is energized for one-half second beyond the ring (or beyond actuation of the carrier-operated relay). If, during the ring, a carrier is placed on the repeater input, a –28V signal is routed to the "master on" relay. The signal must go through the contacts of the ringer, the COR, and the delayed dropout relay; if all three are not energized at the same time, the telephone cannot be turned on without tone control.

If a repeater user is transmitting at the time the telephone starts to ring, the autopatch will not be engaged because the COR cannot feed voltage to the delayed-dropout relay. If he waits until after the ring to transmit, the phone won't answer because the ringer contacts will be open. To answer, the operator must press his transmit key after the phone has started a ring but before the ring has stopped. This concept serves to prevent inadvertent telephone energization yet gives control of the phone to such non-tone-equipped units as handie-talkies.

Twin antennas mounted on the rear cowls keep the author's installation from looking junky. Inside the car, the only visible evidence of a rig is the "Princess" telephone, mounted to the console and modified to serve as a "control head."

On Convenience and Necessity

If you read 73's comments to the FCC's proposed rulemaking for repeaters, you probably saw a reference made to use of an amateur autopatch to save the life of a peace officer. The telephone system used was the one described in this article, and the operator was Don Milbury W6YAN. Don passed the scene of a tragedy involving a highway patrolman and telephoned the police and ambulance directly using his mobile amateur facility. A few miles further down the road, Don accepted a telephone call in his car. The police called him back to express appreciation for his early report and were happy to relate that the officer would live. It will take a lot of ugly towers and TVI complaints to water down at least this one city's opinion of amateur radio.

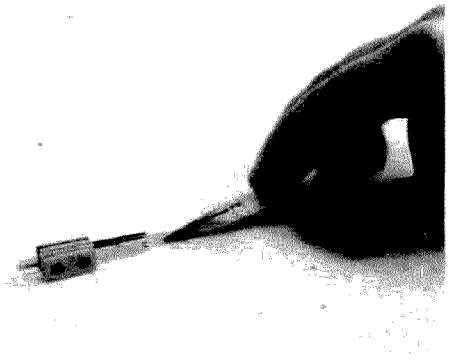
How To Build A Keyer

(and retain your appliance operator status)

Many articles have been written on the subject of building a keyer mechanism for an electronic keyer. The common denominator in all of these projects is that two stationary terminals be placed in some manner and a flexible blade be moved from side to side to make contact with them to form the dots and dashes.



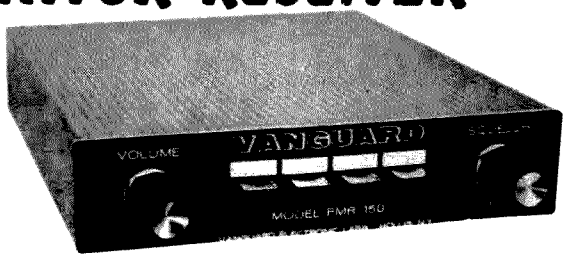
Each article I have reviewed calls for some complex machining operation or using a modified part from a surplus relay. Or a hacksaw blade or some other piece of scrap springy material. More often than not, the simple procurement of the part required costs more in time and energy than would a part specifically designed for the purpose.

There is, however, one commercially produced assembly which costs around a dollar, has contacts rated at 3A, and seems to be a natural for applications such as keyer mechanisms. The part, a switch stack, manufactured by Switchcraft Inc., is a formed-spring switch assembly complete with mounting lugs, solder lugs, and silver contact pads.

The photographs show the three simple steps required to make the Switchcraft part (AA03AA*) into a keyer mechanism.

The first step is to straighten out the middle spring and center it midway

*The Switchcraft stack switch assembly may be ordered for about one dollar from Allied Radio or Newark Electronics, Chicago, Ill.; consult their industrial catalogs for applicable part numbers.

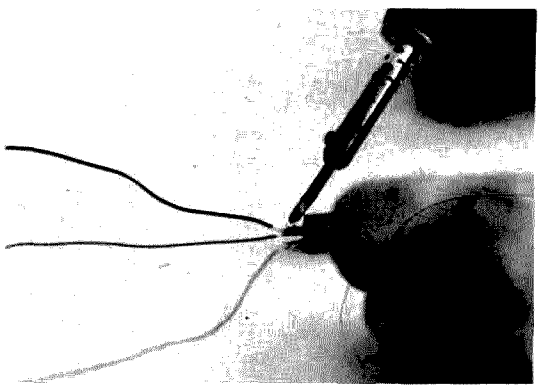


The center spring section has to be spaced equidistant between the two contact points. A pair of long-nose pliers will do the job in a jiffy.

VHF FM MONITOR RECEIVER

NEW

100% MADE IN U.S.A.



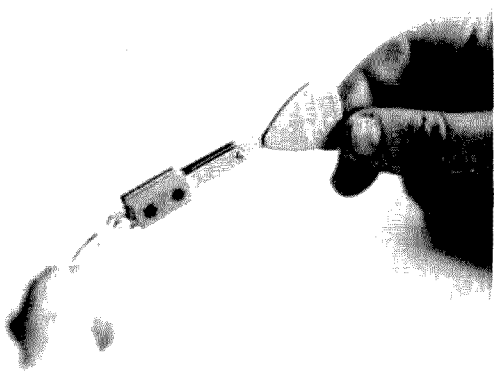
Only $79.95 Postpaid in the U.S.A.

The new **VANGUARD FMR-150** is not just another frequency converter but a co.nplete FM receiver with outstanding performance.

Check the following features and see why it's the best. Collins IF filter for separating those closely spaced stations you hear together on other sets● Double conversion to eliminate interference from image frequencies● Dual Gate MOSFET RF stage for low noise. .2 uv. sensitivity, and minimum cross modulation● Automatic squelch for eliminating noise● Self-contained speaker● Operates on 12v. D.C. negative ground● Heavy gauge anodized aluminum case 6" x 7" x 1-3/8"● Provision for 4 crystal controlled channels at the push of a button● One channel of your choice supplied with receiver. Additional channels available just by plugging in another crystal at $4.95 ea. No need to buy another RF unit as in some other sets● Factory tuned to cover any 6MHz segment from 135 to 175 MHz.

HOW TO ORDER: The **VANGUARD FMR-150** is available only direct from our factory. Include remittance in full plus sales tax if you reside in N. Y. Be sure to state the 6MHz segment you will want to cover and the exact push button frequencies to be included.

VANGUARD LABS Dept. H, 196-23 Jamaica Ave., Hollis, N.Y. 11423



Solder flexible leads to the three contact terminal points so the switch assembly can be mounted without necessity for later access.

between the two outer springs. Long-nose pliers work fine for this job. Next, solder a length of flexible wire to each of the three solder lugs. Now mount the keyer assembly to your board case or what have you with a pair of L brackets made from some scrap metal; use the mounting holes on the assembly and regular screws. No special insulating precautions are required.

The final step is to epoxy two guitar picks to either side of the center spring; then you are ready to hook it to the keyer.

Actually, you will find that it took longer to read this article than to build your keyer. Not only have you become a homebrewer, but the silver contacts add professional reliability to your project. And that sense of "I did it myself" will certainly make this simple project worth all the more to you.

Elliott S. Kanter W9KXJ ■

When guitar picks are glued to the contact spring, the assembly really begins to look like a keyer.

a 2-Channel Search-Lock For FM Receivers

This simple gadget turns a two-channel rig into an automatic scanning type, and provides the added capability of locking on a channel where activity is sensed.

Many amateurs live in an area where the local repeater output is not on the same frequency as the simplex activity. Installation of a "search-lock" scanner will permit you to monitor both frequencies at the same time, on a conventional 2-channel receiver. Included is an optional active channel indicator that lights up to tell which channel is in use. It can be used with any tube-type receiver such as GE Progress Line, Motorola Sensicon series, or any other receiver that uses separate oscillators for each channel. It can be built into a fixed station or a mobile unit with little modification to the basic equipment.

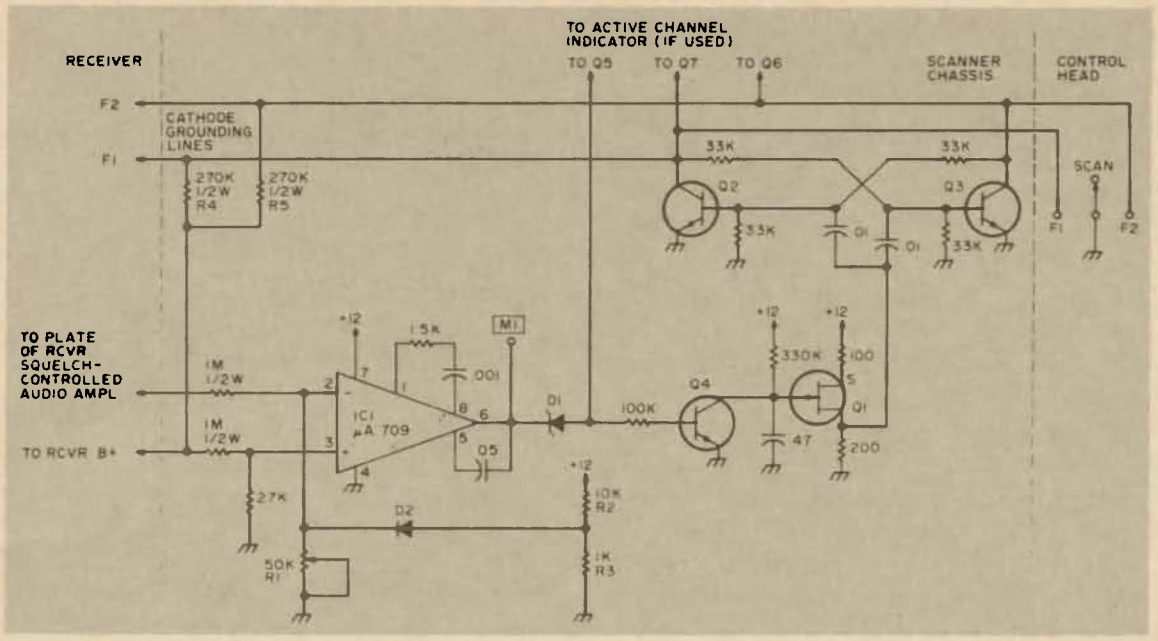

Fig. 1. Two-channel search-lock for FM receivers. The switch is mounted on the control head; everything else may be mounted inside the radio cabinet.

How it Works

The search-lock unit (Fig. 1) consists basically of a flip-flop (Q2 and Q3) with the outputs connected to the cathodes of the two crystal oscillator tubes. As the flip-flop operates, it alternately grounds the cathode of each crystal oscillator for a short time, thus sampling each frequency for a very short period. The flip-flop is triggered by pulses generated by unijunction transistor Q1, at about a 10 pulse-per-second rate. Therefore, each channel is sampled five times per second, for 100 ms each time. This sampling rate is fast enough that no information is lost at the beginning of any received transmission, yet slow enough to permit the crystal oscillators to turn on completely and come up to full output. It is also long enough to allow the squelch to open if a signal is present on one channel. I did not use a faster sampling rate because many crystal oscillators take up to 20 ms to reach full output, and it takes up to 40 ms for the squelch to open on some receivers when a signal is received.

When a signal appears at the receiver input and the squelch opens, the gate circuit will turn off the unijunction transistor pulse generator, and the receiver will stay locked on that channel as long as the signal is received. In this respect, the circuit is similar to that of a carrier-operated relay. The gating circuit consists of a squelch detector (IC1), and gate amplifier (Q4). IC1 is a type 709 operational amplifier wired as a differential switch. I used this circuit because it effectively prevents drift of the gate trigger level with changes in battery voltage when used in a mobile installation.

The positive input of the differential switch (IC1) is connected to receiver B+, and is the reference voltage. The negative input is connected to the plate of the squelch controlled audio amplifier tube.

When no signal is being received, the dc voltage on this plate is the same as B+. When a signal appears and the squelch opens, the dc voltage at this plate will drop. This voltage change is detected by the differential switch (IC1), is amplified by Q4, and switches pulse generator Q1 off.

Potentiometer R1 is the differential switch threshold adjustment. If B+ varies up or down due to a change in battery or line voltage, the differential switch will not operate because it is only sensitive to changes in the ratio of the two input

voltages (and not to changes in the absolute values of these two voltages).

Resistors R4 and R5 provide a "pullup" voltage on the cathodes of each oscillator (switching point in the receiver) to make certain that they go completely off when not grounded through their associated transistor in the flip-flop. They also absorb any leakage currents through either flip-flop transistor.

A switch on the control head is the only operating control needed. It is a three-position type (up, down, and center), and the center position is "on." In the center position, the search-lock operates normally. In either extreme position the associated cathode is grounded directly, and the search-lock is disabled. (See Fig. 2.)

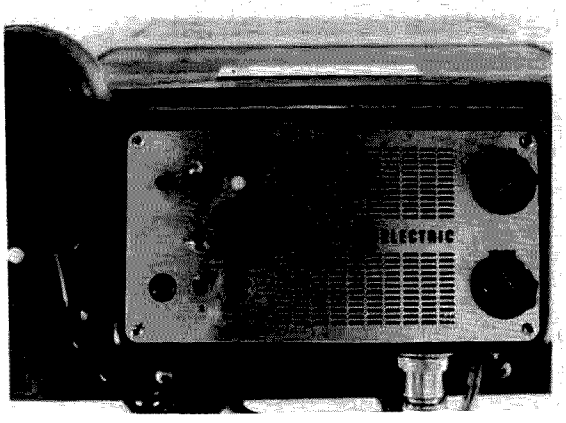

Fig. 2. Search-lock controls mounted on a GE Progress Line front-mount control head. Separate transmitter and receiver channel switches are used. The scan switch is the toggle mounted just under the main power switch. In the extreme left position, the receiver locks on frequency 1, and in the extreme right position, it locks on frequency 2. The center position allows the receiver to scan, thus locking itself on whichever channel becomes active first. The two lamps mounted adjacent to the lower toggle switch provide an indication as to which channel is being used.

The active channel lamp indicator circuit (Fig. 3) is an optional operating convenience that may or may not be included. Transistor pairs Q6 and Q8, and Q7 and Q9, are the lamp drivers. They are controlled by squelch gate amplifier Q5 and inputs from the flip-flop (Q2 and Q3).

When there is no signal present, the lamp drivers are gated off, and neither

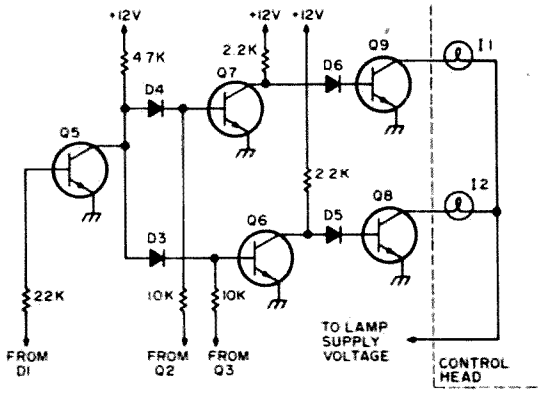

Fig. 3. Optional active channel lamp indicator circuit. The lamps are mounted on the control head.

lamp lights. This was done to eliminate any flashing lights which might be a distracting safety hazard while driving at night. When a signal appears, gate amplifier Q5 turns on, the appropriate lamp driver circuit is turned on, and the lamp lights. As soon as the signal disappears, the lamp goes out, and the search-lock resumes operation. Resistors R2 and R3 and diode D2 serve to keep the squelch gate circuit turned off when transmitting so the channel indicator lamps don't light.

If used in a mobile installation, the entire unit can be powered directly from the 12V battery line. If used in a fixed

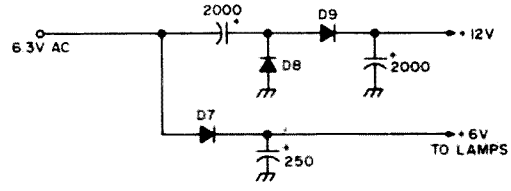

Fig. 4. The ac filament voltage typically available in a tube-type base station can be used to power the search-lock device if this simple rectifier circuit is built.

station, the rectifier power supply in Fig. 4 can be used to supply dc voltage from the filament line. In this case, 6V lamps should be used. (For mobile operation, 12V lamps should be used.)

Construction

Any form of construction may be used. I built my unit on small terminal strips and

mounted them on a plug-in Vector board (Fig. 5). Parts layout is not critical. Small quarter-watt resistors may be used except where noted, and low-voltage capacitors are also satisfactory. Diode D1 is a 1N747, Motorola HEP-102, or similar low-power zener diode of 3–5V. Diodes D2 through D6 are low-power silicon computer diodes such as 1N629 or Motorola HEP-154. Diodes D7 through D9 are low-voltage, low-power silicon rectifiers such as 1N645, 1N2069, or Motorola HEP-154.

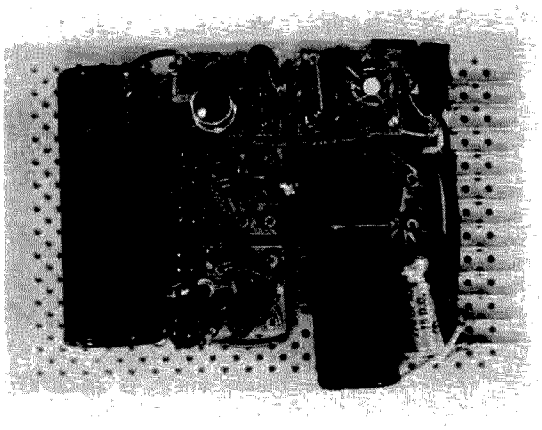

Fig. 5. All components for the search-lock are mounted on a plug-in Vector board.

Unijunction transistor Q1 can be a 2N2160, 2N1671, GE X-10, or Motorola HEP-310. Integrated circuit IC1 is a type 709 operational amplifier. All the semiconductors can be purchased for about $10, including IC1, from Poly Paks in South Lynnfield, Mass. Transistors Q2, Q3, Q5, and Q6 can be 2N3641, 2N706, GE-17, Motorola HEP-50, or any similar type. Transistors Q4 through Q7 can be 2N3565, 2N3860, GE-17, Motorola MPS-6520 or HEP-55, or any similar type. The lamps should be low-power types that do not draw over 150 mA.

Take the usual precautions when soldering to avoid overheating the semiconductors.

Installation

The chassis can be installed inside the case of a mobile unit or anywhere in a fixed station. The only modifications necessary are to separate the receiver channel switching lines from the transmitter lines. Separate switches for transmitter and receiver should be mounted on the control head (Fig. 6). The transmitter switch can be any type with the proper number of positions required for the particular installation.

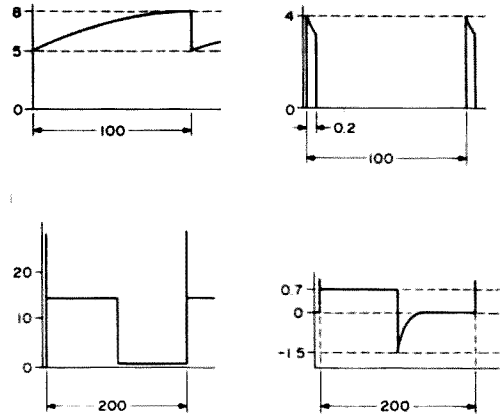

Fig. 6. Waveforms that may help troubleshooting. Waveforms represent a no-signal state, squelch closed. Vertical scale is dc volts; horizontal scale is time (milliseconds).

If you elect to include the active channel indicator lamp circuit, the two lamps will have to be mounted on the control head, and lines run to the search-lock chassis. If the existing control cable doesn't have enough conductors to handle the separate receive and transmit channel switching, plus the indicator lamps, another multiconductor cable can be run to accommodate these wires.

Adjustment

The only adjustment necessary is to set the squelch gate threshold pot (R1). This is done by reading the voltage at metering point M1, the output of IC1. With no signal at the input and with the squelch fully closed, adjust R1 until this voltage drops to just under 2V. Check to see that this voltage rises almost to the supply voltage when you open the squelch.

Troubleshooting

When operating normally, with no signal, metering point M1 should be under 2V, pulse generator Q1 should be generating short pulses at about 10 pps, the flip-flop should be operating, and the lamps, if used, should be out. When the squelch is opened, either manually or by a signal, metering point M1 should rise to near the supply voltage, pulse generator Q1 should not be operating, the flip-flop should be stopped with one side turned on and the other off, and one lamp should be lighted.

The voltages in Table I and the waveforms in Fig. 7 may help when troubleshooting.

Table I. Approximate Voltage Requirements.

	Q1		Q2		Q3		Q4

[1] no signal
[2] squelch opened, channel 1 on, channel 2 off.
Some voltages in the upper row are averages of fluctuating readings while unit is searching.

Conclusion

I have been using this circuit in a GE Progress Line desktop station for over a year, and in a mobile rig for a couple of years with no problems. It greatly increases the convenience and pleasure of monitoring by knowing that I won't miss a call on one frequency because I'm monitoring another.

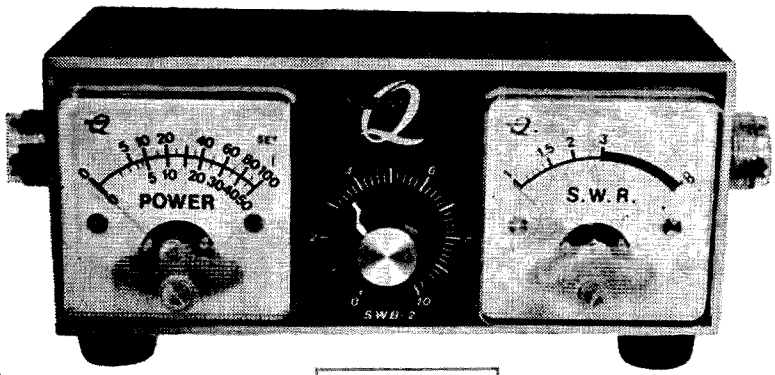
Allied's Portable FM Receivers

In July 1969, Allied Radio introduced two hand-held transistorized FM receivers. Although these units were designed for monitoring of low- and high-band commercial FM stations, the coverage of the receivers include the 10, 6, and 2 meter amateur bands. The A-2586 receiver covers 27-50 MHz (actual coverage without retuning is 26.5 to 52.5 MHz) and the A-2587 receiver covers 146-175 MHz (actual coverage is 145.5 to 178 MHz).

Initial setup of the low-band A-2586 consisted of putting four penlight batteries (included!!) into the unit. A quick tune across the spectrum showed considerable activity on the CB frequencies, local police frequencies, and the low end of 6 meters. The audio output of the receiver was sufficient, but a little reserve might be desirable in noisy locations.

The receiver had no squelch circuit, but the background noise was very low. Only when a station was transmitting would the audio level increase. This gave the receiver the appearance of having squelch without the actual circuitry. An earpiece, included with the receiver, allows private listening.



The receiver is quite stable and is fairly selective. Two local police departments have frequencies separated only by 40 kHz. When tuned to one frequency, only slight splatter from the other was heard. Since Allied makes no claim as to the sensitivity of the receiver, a quick check was made with a calibrated attenuator. The receiver had a sensitivity of 1.5 μV for 20 dB of quieting. Although this is not extreme sensitivity, it is certainly adequate for use in areas where a repeater is operating.

The only deficiency found was the attached antenna, which proved too short for maximum sensitivity. A 6 ft length of wire plugged into the external antenna jack im-

"Northern California's Most Complete Ham Store"

proved the receiver performance considerably. It may be possible to base-load the existing antenna to improve performance; otherwise, the low-band receiver works fine. If complete coverage of the 6 meter band is desired, the receiver may be slightly retuned with only a small loss of 27 MHz coverage.

The high-band receiver arrived after the tests on the low-band receiver were complete. Upon arrival, the receiver was activated by placing the batteries into the proper holder. The Fort Worth 146.94 MHz repeater was immediately heard with a full-quieting signal. (This repeater is approximately 35 miles from my residence!) Tuning up the band provided many other signals, including taxi, mobile telephone, RCC, paging services, etc. The high-band receiver, incidentally, does not suffer from a too-short antenna. The attached whip can be set for a quarter wavelength for optimum performance. The A-2587 high-band receiver had considerably more audio output than the low-band version. Thus, the receiver did not act as if it had a built-in squelch circuit. However, the background noise is not objectionable. Since the receiver seemed fairly sensitive, checks were run on it to compare. The sensitivity ranged from 3.0 μV for 20 dB of quieting at the low end to 5.5 μV at the high end. (The usable, or threshold, sensitivity is actually much better than the "quieting" sensitivity, and is a more meaningful standard when no squelch is employed.)

Both receivers performed excellently with outside antennas. Because of their small size and low cost ($17.95) the receivers give the amateur portable coverage of the 6 and 2 meter FM frequencies as well as the 11 meter CB and 10 meter amateur frequencies. The construction is excellent. The serious FM'er may want to crystal control the receiver for signal-channel operation. There is sufficient room inside the case for an oscillator circuit.

If the receiver is to be used at a fixed location, it is desirable to obtain the ac adapter ($3.95) which simply plugs into each receiver.

All in all, the Allied A-2586 and A-2587 are well worth the small investment.

450 MHZ MIGHTY MITE

E.R. Davisson K9VXL
83 Crestview Drive
Greenwood IN 46142

Have you ever wondered what kind of activity occurs on the ¾ meter band? I suppose you've been curious, like many others, but not sufficiently so to go to the trouble of whipping up a converter or receiver to find out. Well, here is an extremely simple circuit which will allow you to determine if you would like to go to the expense and trouble.

Figure 1 shows the schematic of a simple transistorized superregenerative receiver which will work easily at 420–450 MHz. This circuit provides exceptional sensitivity. If your hearing is good, you may connect a pair of earphones directly to the circuit, although the level of audio is quite low. The more ambitious may, of course, build up a small audio amplifier, borrow one from an old transistor radio, or use an RCA CA3020 integrated circuit audio amplifier.

The transistor used is a relatively new device from Fairchild – a 2N4916, which costs less than a dollar. This transistor is rearing its head as an excellent low-cost device featuring a beta of over 150 at 450 MHz.

No special parts have been used and the only problem area may be the choke in the audio output lead (RFC2). I used the secondary of a driver transformer from an old transistor radio. The value of inductance was around 160 mH. A choke closer to 30 mH would probably be better but doesn't appear to be too critical in this circuit.

Several liberties were taken with this circuit that may or may not appeal to you. Since I was interested in only one frequency, a "gimmick" capacitor (twisted leads) was used to tune the circuit to that

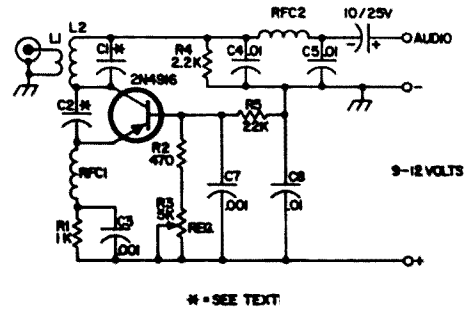

Fig. 1. Schematic diagram of the Mighty Mite *superregenerative receiver for the ¾ meter band.*

frequency. This also alleviated the work involved in providing an insulated shaft for a small variable capacitor. Other means are available for tuning this simple circuit, such as by shading L2. This would provide a means of covering a spread of frequencies but would make the receiver more complex mechanically; and since I wanted to keep it simple, no attempts were made along these lines.

Figure 2A shows the foil side of the printed circuit board and 2B shows the component side. The tank coil, L2, was made from printed circuit board and its size and shape is shown in 2C.

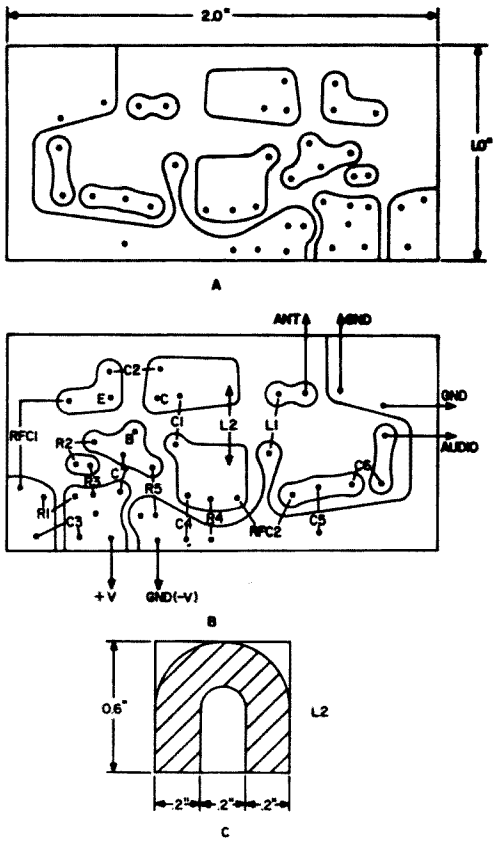

Fig. 2. Suggested PC board layout for the receiver. The foil side is shown in 2A and parts location in 2B. The tank coil (L2) is also made from PC material and shown in 2C.

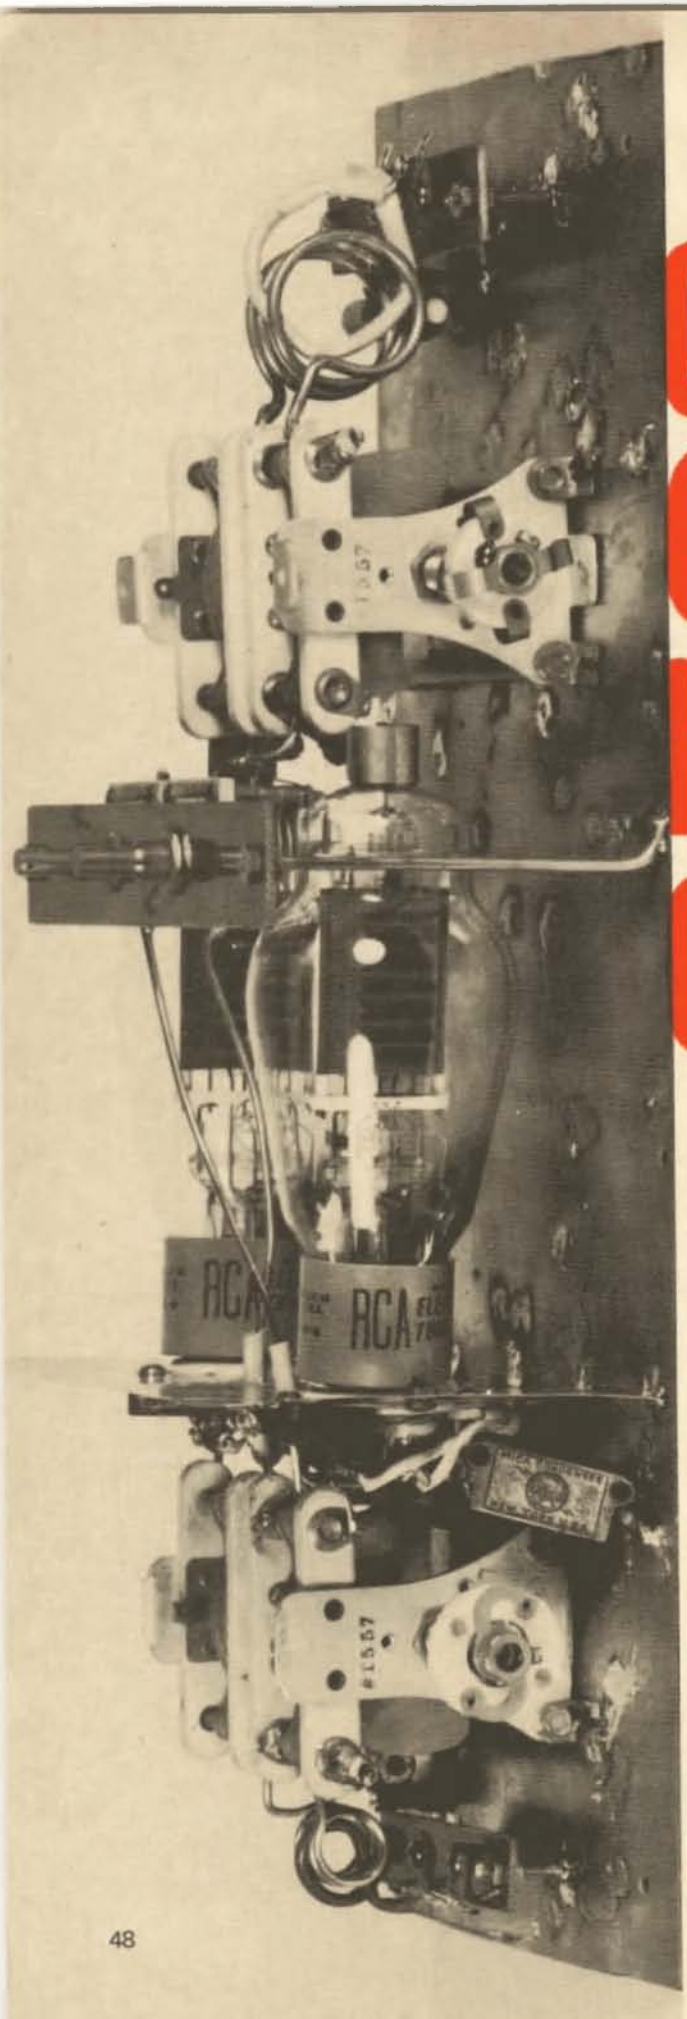
Again to keep the circuit simple, L1 and L2 are both soldered to the foil side of the board. The more ambitious builder could make slots in his main board to accept L2, so that it would be on the parts side of the board. L2 is soldered perpendicular to the main board with the foil side facing L1.

L1 consists of 1½ turns of hookup wire (3/16 in. ID) spaced approximately ¼ in. from L2 and parallel with it.

C1 is a gimmick capacitor made from two ¾ in. lengths of hookup wire and twisted together. This provides sufficient capacity for oscillation, but is still small enough not to lower the frequency of the tank too far.



As mentioned previously, C2 is also a gimmick capacitor, only in this case it consisted of two 3½ in. lengths of hookup wire twisted to achieve the frequency of interest. If you take this approach, you might try shorter lengths (such as ½ in.) and try various fixed capacitors, starting at about 1 pF. The total capacity required depends on several items such as output capacity of the transistor used, feedback capacity, and closeness of L2 to the box used to mount the circuit board. In my case, no box was used, so this factor hasn't entered into the design as yet. If you do place this circuit in a box, just remember to make the box as large as possible to keep the sides away from L2.

RFC1 consists of 4½ turns of 16 AWG enamel wire wound on a ¼ in. slug using an AM oscillator coil from an old transistor radio.

After the circuit is built, connect a pair of earphones or an audio amplifier and apply power. If no hiss is heard, slowly adjust the potentiometer until the hiss is heard. The most sensitive position is where oscillations just occur. Try adjusting the spacing of L1 and L2 for sensitivity as well. On my version, a 10 μV signal could be easily detected with L1 about a foot away, so no trouble should be experienced in detecting a signal.

Due to the small size and relative ease of construction, this circuit could lend itself to a 432 MHz transceiver walkie-talkie.

Although this circuit won't give you the results of a multistage converter, at least you can now check to see what's happening with the ATV boys inexpensively and decide whether or not you want to spend more time and money to build something better. . . . K9VXL ■

CHEAPIE 6-METER HALF-GALLON

It works out to $12.50 a quart, and features low-cost tubes, no screen voltage, no bias voltage, no blower.

This article describes a final rf amplifier for 6 meters that will put *out* nearly 400 watts on CW or FM telephony (or a good quarter kilowatt *out* on AM phone). In case you or your buddy haven't a pair of 811As lying around, you can buy them new for only $7.75 each. With only two of these tubes, a couple of two-gang balanced capacitors, a few knobs and jacks, and you're on the air. And it can't cost you over $25. For the amplifier, that is. Of course, if you don't have a husky power supply lying around the costs will start to mount a little.

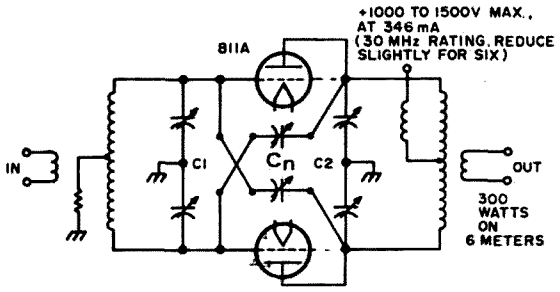

Fig. 1. There's nothing complicated about the half-gallon 6 meter rig as this simplified circuit diagram shows. Put 1000V on the centertap of the tank circuit and she'll draw almost 350 mA at resonance.

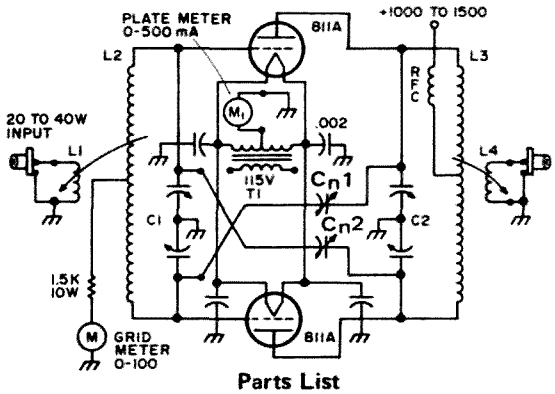
The Main Idea

Filling a "one-of-a-kind" contract recently involving construction of a "radio frequency power supply" which called for 5 kV (yes, five thousand volts) at 70 MHz to be used in ionization work, several things came to my mind for amateur homebrew work. Ruggedness, simplicity, smooth tuning, and low cost were among these thoughts, and when I finished, it looked and acted like something of considerable interest for 6 meter hams.

A lot of fine tubes have come out since the 811As appeared some 25 years ago; but which among them will give you nearly 400 watts of FM output for $15 a pair, *new*? Also, without screen voltage, bias, blower, or screen modulation?

As just one example of these hard-to-beat tubes still being used after 25 years, see the "1 kW Economy Linear Amplifier" in the Radio Handbook (Editors and Engineers, Ltd., Indianapolis, Ind.); it has four 811As in parallel.



The Circuit

Figure 1 shows how standard and simplified the circuit is. Just take a few precautions as noted in this article, and refer to Fig. 2 for details. One of the advantages of push-pull circuitry concerns the almost complete absence of bypassing requirements (just C3, 4, 5, and 6 on the filament leads). You can bypass the grid and plate return but if L2 and L3 are really centertapped there will be no rf on those leads anyway.

Be sure to keep your fingers away when operating. Remember, they only use 1900V even at Sing Sing!

Neutralization

These 811A tubes are "old-fashioned" triodes but I notice a lot of circuits using them in the latest handbooks. They do require proper neutralization to work good as trouble-free amplifiers at 50 MHz – not critical though, just the proper kind. Since these are "zero-bias" tubes, you can apply 500 to 1000 volts on the plates with no external bias needed and, if not yet neutralized, and L2 and L3 are anywhere near in tune, they will take off and oscillate in great style with several hundred milliamps on the plate meter. This you *don't* want; so, using considerable care and a long, insulated handle, vary neutralizing capacitors C_n1 and C_n2 so that no oscillations occur when L2 and L3 are resonated back and forth across the band. The proper neutralizing capacity is not hard to find, but be sure and rock C1 and C2 *all* over the 6 meter band while adjusting the C_n capacitors. The grid-to-plate capacitance C_{gp} for the 811A is listed as 5.4 pF. I used high-voltage 10 pF capacitors, variable – and sure enough, the dial knobs (which are handy for logging the correct spot for neutralization) ended up near the middle of these scales. Once neutralized, the rig can tune all over the 6 meter band so smooth it seems like magic.

Parts List

C1, C2	Bud 1557, spaced 3/32 in.
C_n	Bud, 6-plate (=10 pF)
T1	6V CT at 10A
C3, C4, C5, C6	.002, 1 kV
L1	1 or 2 turns coupled into L2
L2	6 turns (14 AWG), ¾ in. O.D.
L3	1/8 in. copper tube, 1½ in. O.D., 6 turns
L4	1 or 2 turns link (10 or 12 AWG)

Fig. 2. This complete schematic shows all the details for constructing the final, and gives the information necessary to include proper metering.

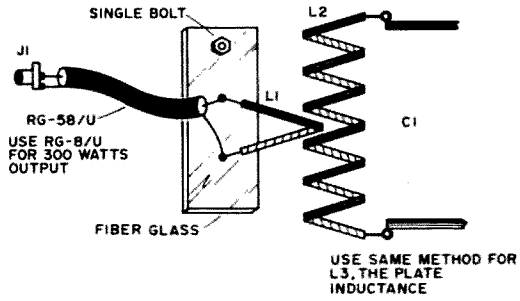


Fig. 3. An effective semifixed link coupling method can be obtained with the link mounted on a pivotable piece of fiber glass.

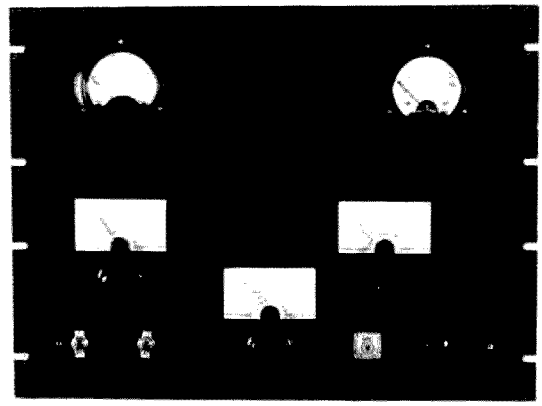

Fig. 4. This photo shows how a complete high-powered transmitter can be obtained using the simple two-triode final.

Layout

Being a fanatic about copper-clad Bakelite (or fiber glass if you're fussy), for baseboard use in experimental work with transistors, I tried one here and the results were equally good. The lead photo shows the layout used, which works fine, either by itself or bolted on a chassis when finished and in a cabinet with dials, input and output jacks, etc. Be sure and use short copper leads for all the rf connectors – especially for the neutralizing circuits and plate tuning components C2 and L3.

Actually, with push-pull circuitry you hardly need a metallic baseboard, but it does allow for easy construction and grounding. And when finished you can bolt it down onto a chassis without change in its operation.

The two flexible couplings on the variable capacitor shafts can be seen in the lead photo. These allow easy placement of the shafts into the back of the Millen dials and take any strain out of misalignment.

Filament Leads

I used 10-gage here because I like plenty of voltage on the filaments. Be sure to mount T1, which should have at least a 10A current rating, as close as possible to the sockets. Each 811A draws 4A, which is one of the reasons they work so well. There is nothing like plenty of electron emission for action! You can even light a 20W bulb at J2 just from electrons going over to the plate through the grid with the B+ lead *open!* You'll also find up to –400V at that point, due to those same electrons landing there.

When you do apply the regular dc plate voltage of some 1000 to 1200V a 200W bulb should light up at J2, but good.

Link Coupling

As usual, with good tuned circuits, not much coupling is needed. One or two turns about halfway in will do the job when loaded into a good tuned-up beam antenna. Both the C1–L2 and the C2–L3 circuits handle very well, with no jumps or odd spots. You will find that overcoupling to L2 shows up with two-peak tuning. Move L1 further out of L2 and good single-peak smooth tuning will be restored. And, once again, be sure and keep your cotton-pickin' fingers off those coils. We don't like to lose readers.

Semifixed coupling links can be used, as shown in Fig. 3. The two terminals can be mounted on a movable piece of linen-based or fiber glass insulating sheet, and fastened with a single bolt to the baseboard for easy adjustment in and out of tuned circuits L2 and L3.

The lead photo shows two bolts for mounting L1 and L4. Suit yourself on that. L4 should use fiber glass insulating tubing, or air spacing. Don't forget there's plenty of fire in L3! Adjust rf output link L4 for a slight dip in plate current at resonance, which should coincide with maximum rf output. If you apply the old-fashioned pencil test to L3 when unloaded, be sure to fasten the pencil to a long wooden handle first. You're dealing with over half a horsepower there! The photo of Fig. 4 shows the front panel used on my job. The

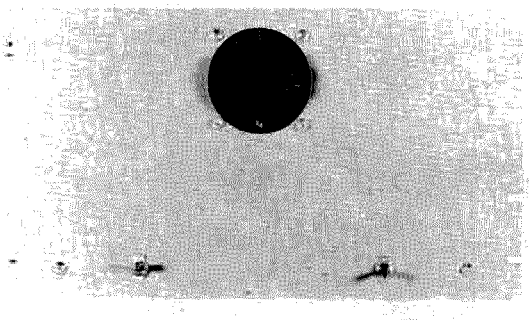

Fig. 5. A Powerstat control on the power supply for the author's rig permits variable voltage delivery from 0 to 1.2 kV.

three Millen dials are used for logging purposes; two of them tune the grid and plate, and the third is for the 70 to 80 MHz oscillator (which, of course, is unnecessary for a straight rf amplifier as described in this article).

Power Supply

Inasmuch as the 811As are 25 years old, I had to dig way back into the cellar to come up with a collection of power transformers, chokes, 866 rectifiers, etc. dating from my 2 meter kilowatt days in the 1946–1949 era. Most of these items have *increased* in value during this time, and they still did a very good job in delivering some 400 watts for the 811As. All you need, basically, is the type 21 Powerstat knob and two toggle switches on the front panel, as shown in the photo of Fig. 5. The Powerstat controls the 0–1.2 kV of the high voltage supply.

If you need to build such a high voltage supply you will have to dig quite a bit through handbooks and mail order catalogs. RCA's invaluable "Transistor, Thyristor, and Diode Manual" is the best help I found.

In the bridge rectifier department, the RCA manual has the "direct replacement for 866 rectifier tubes" in the CR 275 stack, and going back to the Allied catalog you can find its price, which is $22. Or you can string your own diodes together if you want some savings here.

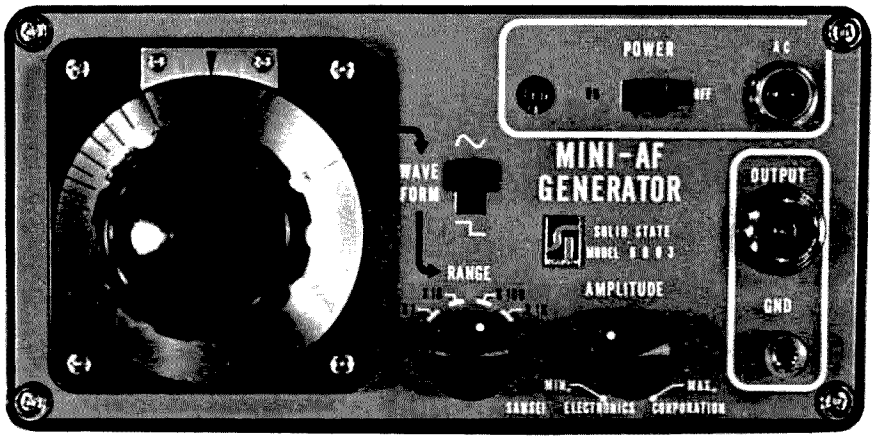
There is a lot of talk in some handbooks about "TV replacement transformers" for use in HV supplies and with the silicon rectifier stack in mind I spent quite a bit more time browsing through the catalogs, again with only medium results. Prices for anything approaching 500W run from a low of $18 to up around $50 for transformers that will give 1500V at 400 to 500 mA. Most manufacturers seem unable to decide on what they do want to offer to customers. Guess I'll have to make an investigation into this matter.

The New Look In Power Supplies

This trend seems to me a mixture of striving for less weight, size, and cost, and at the same time trying to keep "within reason" on the side of reliability and safety. You will have to be your own judge as to the results.

For example, voltage doublers are used to get 2 kV from a 1 kV transformer and you are flatly invited to "try the transformer out and see if the center windings to core insulation breaks down" under the not-designed-for high voltage. At least you are warned! Further, six electrolytic capacitors are strung in series to make up a 2.5 kV capacitor, and the bleeder resistors are composed of the series balancing resistors used across each capacitor in this lethal device. This one can really buy the farm for you with its *10-second* discharge time! Once again, however, you are warned about it.

Modulation



The amplifier shown here can be set up for any of four modulation methods: AM, linear, FM, and SSB. There aren't any screens to worry about and the tubes are zero bias, so it's easy to plan for. Once again, suit yourself on the mode used. Oh yes, it works great on CW also.

Homebrew Power Considerations

As a parting comment, I would say that this whole question of rf power, dc power, and cost to produce them needs looking into. Even more so on 2 meters because of the tubes, the 811As, not being recommended on 144 MHz. There is a tremendous shortage of low-cost, high power triodes for 2 meters! The 4X250s work good and put out real fire, but you start in with $35 and then have to set up a continuous blower and "chimney," a fancy socket, a screen supply, and a bias supply.

LABORATORY QUALITY-POPOLAR PRICE -AURIO SIGNAL GENERATOR

Range 10–100 kHz

Measuring only 7½" x 3¾" x 3¾", and weighing slightly under 2 pounds, the Sansei 6803 Mini-Generator is a completely solid-state sine and squarewave instrument of unusually high quality. Especially suitable for field engineers, broadcast stations, and government agencies, this little beauty is winning favor among our ham fraternity as well.

Of Wein bridge design, using an FET oscillator with both a thermistor and copious amounts of inverse feedback, the output is maintained at minimum distortion and constant level (less than 0.3% for the range 200 Hz–100 kHz with less than 0.8% between 10 and 200 Hz). A stabilized power supply (100–120 VAC 50/60 Hz input) is held to 0.1% against incoming fluctuations.

Squarewave risetime is only 0.2 μs – the output impedance is 600Ω ± 100Ω unbalanced. This beautifully built miniature instrument can be of incalculable value to audio buffs, technicians, and even those of us on sideband who want proper measurements. Shipped postpaid in U.S. and Canada: only $75.00.

a high performance POWER SUPPLY using an IC voltage regulator

Gary V. Fay KØECF/7
Motorola Semiconductor Products Inc.
Phoenix AZ

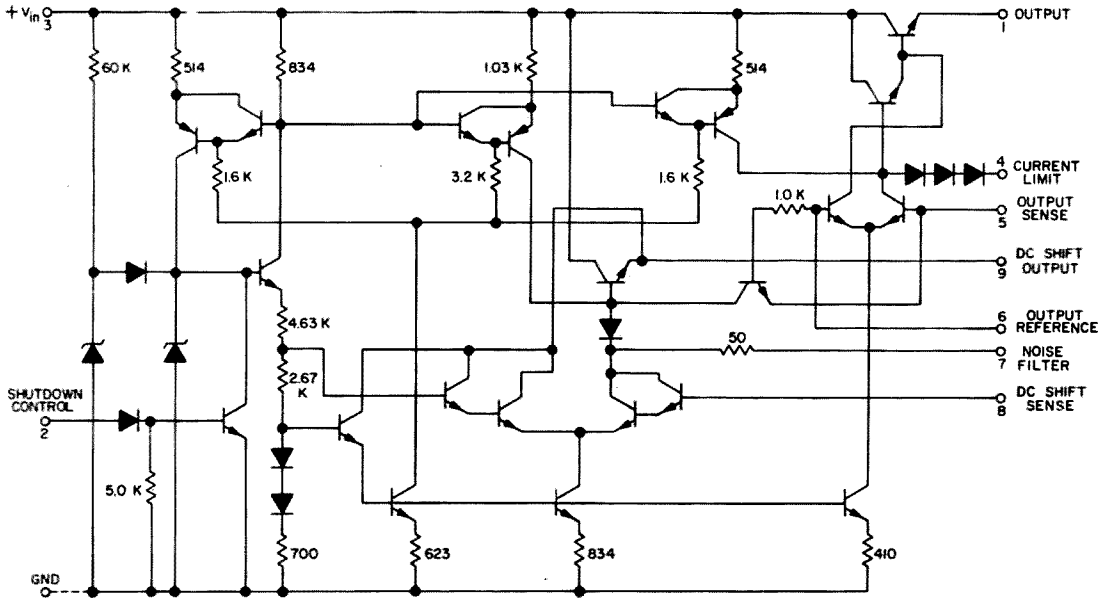
Introduction

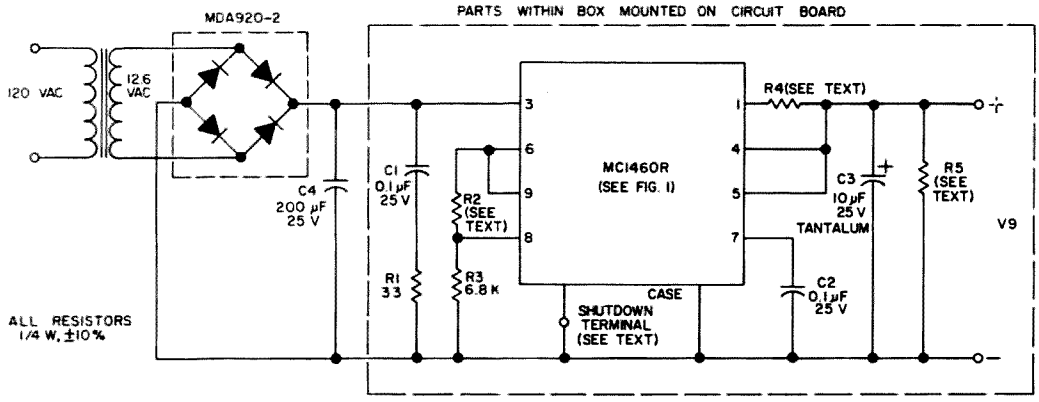
The function of a dc voltage regulator is to maintain a ripple-free output voltage that remains constant in value, independent of changes in input voltage, load impedance, and temperature. A complex circuit must be used in order to construct a regulator that provides excellent regulation, fast response time, low output ripple, low output impedance, transient-free output, remote voltage sensing, and current limiting. Also, the number of components necessary makes the constructed circuit occupy a relatively large volume if discrete components are used. However, a complex regulator exhibiting good regulation can be constructed as an inexpensive integrated circuit and assembled into a package that occupies a very small space. The Motorola MC1460R monolithic voltage regulator is such a circuit; it is packaged in a single 9-pin TO-66 case, yet can supply an output current of 500 mA with no external semiconductors. This device can reduce the parts count and the volume required for a regulator while maintaining excellent operating characteristics and low cost ($5.25 to $8.25).

The MC1460R can be combined with a small etched circuit board to form a complete, well regulated power supply that can be built in a space not much larger than that required for the power transformer and filter alone. The MCR1460R is designed for input voltages up to 20V; for higher voltages, the MC1461R is identical except that it is useful up to 35V.

Circuit Operation

The MC1460R is basically a series-pass regulator with access to the internal amplifiers. A discrete representation of the MC1460R circuit is shown in Fig. 1, with a complete regulating circuit shown in Fig.2. The series-pass transistor is the output device of a Darlington circuit driven by the control differential amplifier. The dc refer-





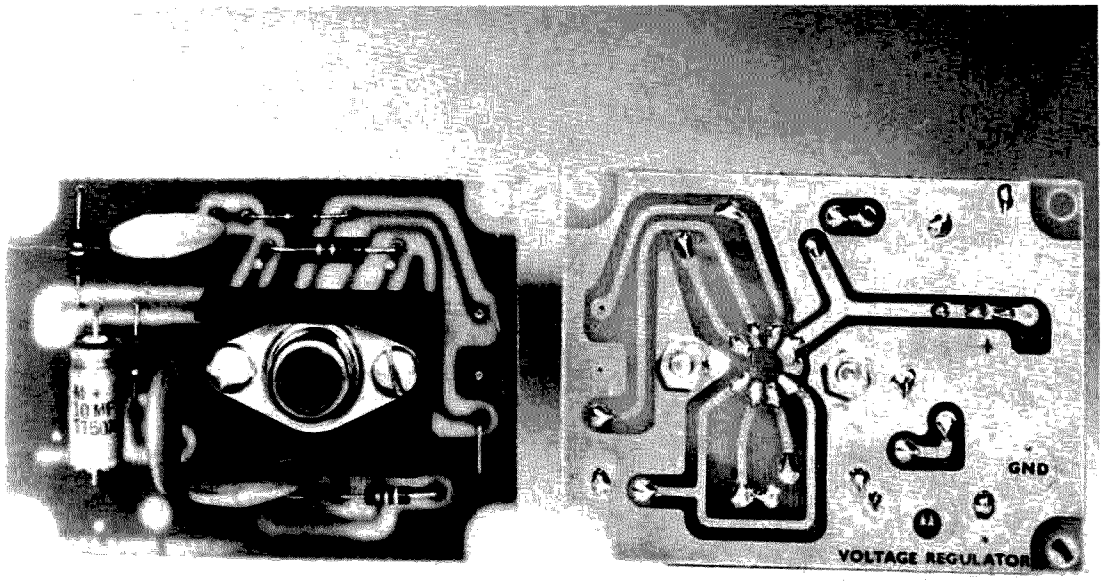


Fig. 1 Schematic of MC1460R integrated-circuit regulator.

ence to the control differential amplifier is provided by an internal series regulator. The reference input to the internal regulator is derived from a zener which is buffered by a transistor amplifier. This voltage is divided by a series resistor–diode string. The output voltage of the internal regulator, which appears at pin 9, is determined by resistors R2 and R3 (Fig.2), connected between pins 9 and 8, and pin 8 and ground. Pin 9 is then connected to pin 6 to provide a reference to the control differential amplifier. The other input to the control differential amplifier (pin 5) is tied directly to the output. Thus the main control amplifier is operated with unity gain to provide optimum ac and dc performance and the output voltage of the main regulator is equal to that of the internal regulator.

By connecting a resistor from pin 1 to pin 4 (in series with the load), the output current can be sensed and limited. This occurs when the voltage across R4 is large enough to forward-bias the internal diode string. Since two of the diodes compensate for the base–emitter drops of the output transistors, a voltage equal to one diode drop is sufficient for this to occur. When this happens, base current drive to the output Darlington transistors is diverted through the diodes. An equilibrium is reached which provides just enough base current to forward bias the diode string. Due to the large amount of feedback used in the main control amplifier, the tran-

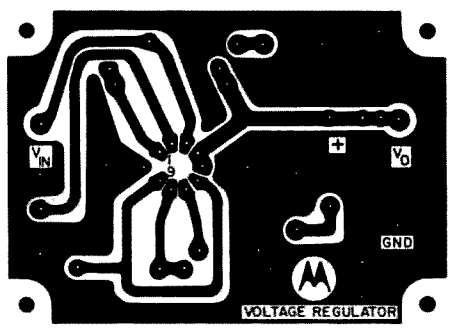
Fig. 2 Regulated power supply using intergrated circuit voltage regulator.

Front and back views of etchedcircuit board used for IC regulator.

sition from voltage regulation to current limitation is very sharp.

Construction

All of the parts for the regulator in Fig. 2 except the power transformer, bridge rectifier, and filter capacitor can be placed on the etched circuit board shown in Fig.3.



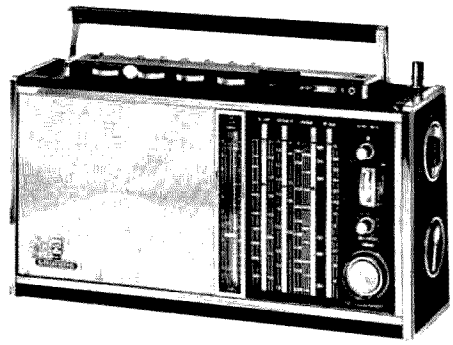


Fig. 3. Etched-circuit board used for regulator. Available for $1.25 from Project Supply Co., P.O. Box 555, Tempe AZ 85281.

The board is available for $1.25 from Project Supply Co., P.O. Box 555, Tempe AZ 85821. This provides a convenient way to construct an operating circuit and also controls the lead dress used in construction. This will minimize possible parasitic oscillations that may occur due to phase shift from reactive elements. The high gain and wide frequency response of the monolithic regulator makes this a problem at frequencies up to 60 MHz, so even stray wiring capacitance can cause oscillation. Thus, high frequency construction practices are necessary to prevent oscillation possibilities.

The MC1460R must be mounted on a heatsink for high power dissipation. In this case, the passive components are mounted on the copper side of the board. The heatsink must be spaced away from the board to prevent shorting to the leads of the components which project through the board. A suitable sink is the Thermalloy 6168. Silicone grease should be used between the IC and the heatsink for best heat dissipation, and insulation should be used on all leads to prevent shorting to the heatsink.

GRUNDIG SATELLIT-AMATEUR 210

Yes, it copies Sideband and CW too!

FOR SHORTWAVE A highly sensitive receiver whose selectivity can be switched to wide or narrow for optimum results on sideband or AM. And for serious DXing, just plug in an external antenna.

FOR FM Hi-fi quality through broad bandwidth, high-power audio, and multiple speaker arrangement.

FOR SWL Easy tuning on a number of selectable bands. This receiver is sensitive enough to pull in even the weak stations without an external antenna.

Function	Band (MHz)	
Bandspread	28.3–29.8	Longwave
Tuning	26.9–28.3	150–450 kHz
(includes CB)	20.9–21.7	
	13.8–14.5	
(includes CHU)	7.0–7.35	Broadcast Band
(SW Broadcast)	5.95–6.25	510–1650 kHz
	3.5–3.8	
	1.7–2.0	HiFi FM (Wideband)
(includes 75m)	1.6–5.0	88–108 MHz (AFC)

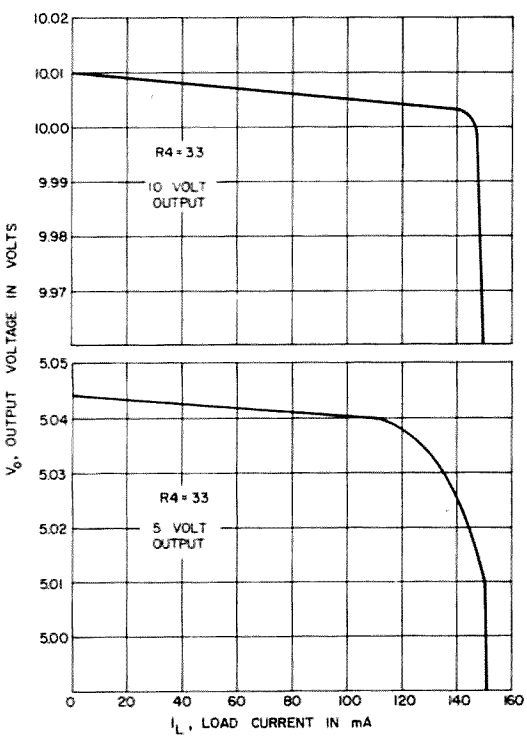

Fig. 4. Output voltage vs load current at 20V input.

Output Regulation

The curves of Fig.4 show that excellent voltage or current regulation can be obtained with the assembled circuit. No heatsink was used for these curves. For the regulator used, the output voltage varied only 2 mV for the 5V setting from 1 to 120 mA of load current, which corresponds to a load regulation of 0.04%. Less than 10 mV of change in the output voltage could be observed for the 10V output with up to 130 mA output current, which is less than 0.1% load regulation. This performance results from the combined effects of output impedance and junction heating. The effect of output impedance tends to make the output voltage fall while junction heating effects from increasing load current tend to make the output voltage rise.

The high gain of the MC1460R makes the transition region between the voltage- and current-regulating modes very small and the current-limiting region very sharp. Thus, from 9.99 to 0V output, the current

varies by only 3 mA from its limiting value of 150 mA.

Input Regulation

The dc input regulation characteristics are shown in Fig. 5 for load currents of 1, 50, and 100 mA for both 10 and 5V output. Again junction heating effects are present and result in the 0.01%/V regulation shown. The ac input regulation, although not shown, is typically 0.003%/V.

The minimum input–output voltage differential for the MC1460 is 3V. Thus, when the output is set for 10V, the required input is 10V plus 3.0V, or 13.0V. For 5V output, the minimum input–output voltage requirement would give an input voltage of 8.0V. However, the minimum input voltage for proper operation of the MC1460R is 8.5V, and this would be the required input voltage for anything less than 5.5V output.

Power Dissipation Limitations

When the input voltage is at the maximum rated input of 20V and the output is shorted, the regulator must withstand this voltage and supply the short-circuit current I_{SC}, which is itself set by R4 according to the following formula:

$$R4 = \frac{0.5V}{\text{max output current}}$$

For example, with an R4 of 3.3Ω, I_{SC} will be 150 mA. For 20V in, 0V out, this gives a power dissipation of 3W. Therefore, the package would have to be mounted on a heatsink. The amount of heatsink area required depends on the ambient temperature and in this example would have to be enough to keep the case below a temperature of 127°C.

Output Voltage Adjustment

The output voltage is set by the values of resistors R2 and R3. The voltage at pin 8 is typically 3.5V. To minimize the loading effect due to base current on the voltage at pin 8, a current of about 0.5 mA is required through resistor R3; thus, its value should be about 6.8 kΩ. Although a low temperature coefficient is not required for these resistors, the *same* temperature coefficient is necessary to keep the ratio independent of temperature so that the output voltage is constant over temperature.

Shutdown Control

Both the MC1460R and the load current can be turned off (or "shut down") via the shutdown control at pin 2. Under this condition the output voltage drops to almost zero, allowing only a few microamperes to pass through the load. The shutdown control voltage can be provided by any saturated logic such as DTL, RTL, TTL, etc. If shutdown is not necessary, pin 2 should be grounded to prevent spurious signals and inadvertent connections from shutting down the regulator.

Conclusion

The basic MC1460R integrated circuit voltage regulator is seen to be a useful component which operates with a minimum of external components and without the need for external semiconductors. The outstanding performance achieved by the regulator can be obtained at a relatively low cost.

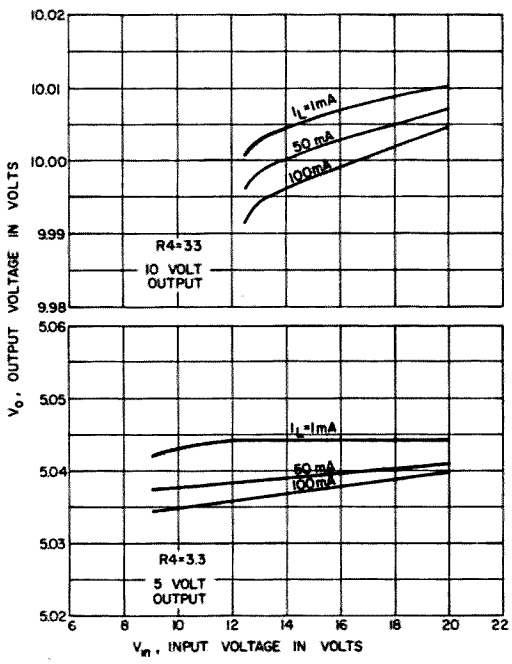

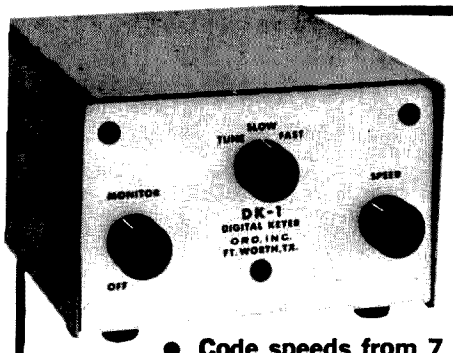

Fig. 5. Output voltage vs input voltage at various load currents.

THE **DK-1** DIGITAL KEYER

is designed to allow the CW operator to transmit morse code with a MINIMUM of hand motion. No other keyer exceeds the DK-1 in this respect.

● Code speeds from 7 to 60 WPM with correct inter-letter and inter-word spacings ● Mercury reed relay for transmitter keying and receiver muting ● Input for manual key ● Keying monitor with built-in speaker ● 18 integrated circuits, 12 transistors, 5 diodes

These examples illustrate the minimum hand motion required. The dot and dash keys may be closed or released in the order indicated within microseconds of each other.
"A"—Close dot-dash key. During the dot or dash, release dot-dash key.
"R"—Close dot-dash key. During the dash or second dot, release dash-dot key.
"P"—Close dot-dash key. During the second dash or dot, release dash-dot key.
"L"—Close dot key. During the first dot, flick the dash key. Release dot key during the last dot.
"B"—Close dash-dot key. Release dash key at any time during the three dots and dot key during the last dot; or, release dash-dot key during the last dot.
"Double Dash"—close dash-dot key. Release dot-dash key during the last dot or dash.

Note that in the above examples, only one depress-release cycle of the dot and dash keys is required. All letters, numbers and punctuation marks may be generated using variations of this technique.

A Soldering Gun Tip...

Steve Harrison WB6PKA
27978 Beechgate Dr.
Palos Verdes Peninsula CA 90274

73 Magazine carried a little tip in the July 1969 issue for prolonging the life of the standard soldering gun tip (no pun intended). The method described involved heating a regular copper tip with a propane torch and tinning the copper tip with silver solder. This method is good, but it seems to be a heck of a lot of work to prolong the life of a little piece of copper wire. Most of us have found that a little piece of 14-gage common copper housewire will replace the half-dollar tip for the guns that are bought. Why not go one step further and, instead of using copper wire, use the silver-plated grid tuning lines from the final of the common surplus 522 VHF transceiver? Many of us experimenters have such units kicking around in the basement that have been cannibalized for parts, and if the grid lines are still there, they can be put to immediate and good use.

Other sources of silver-plated wire probably come to your mind as you think of the 522, and as long as the wire will fit into the gun, the wire will work. If you will just take it easy and let your gun cool off a little now and then, the gun just *might* last as long as your new tip!

Make Your Soldering Gun Tip Last Longer, by William P. Turner, WAØABI, 73 Mag, July 1969, Page 127.

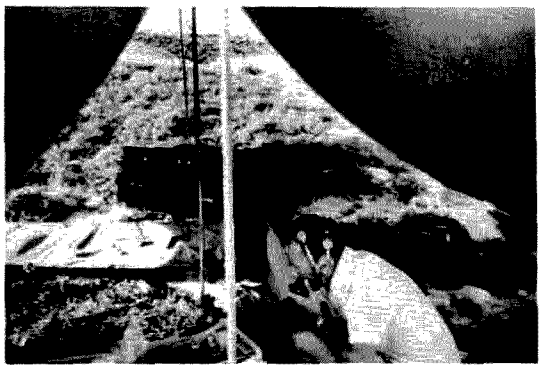
Latham Island

Garth Hamilton 5H3LV
Box 717 STN "Q"
Toronto 290 Canada

As some of the world's DX population know there have been many attempts to get permission to operate from Zanzibar and its islands. Zanzibar is composed of Latham Is. or Fungu Kizimkazi, a bird sanctuary southeast of the main island of Zanzibar and Pemba Island to the north-northeast of the main island of Zanzibar; also included are the islands of the Zanzibar Channel from Pemba in the north to Kizimkazi or Latham in the south.

There has been a long pursuit for permission to operate, which started in January 1969 and proved fruitless as no replies or acknowledgment to any correspondence were ever received. In Sept. 1969 I approached Bill 5H3KJ, on the matter as we had been friends for aboul a year and I had by this time also learned the intricacies of procedure of the country and its people. So, after several discussions I decided to write to the office of the first vice president which is also the office of the president of Zanzibar. (To be noted: Zanzibar is completely autonomous within the union of Tanzania.) Once again the long wait began. Early in 1970 I learned that people were asking friends about me so I figured another security check was being made similar to the to the initial one upon my first request to operate in Tanzania in July 1968. It was this which prompted me to start things moving again, knowing that in six to eight weeks I would have an answer. So Bill and I started planning the final details in late January, projecting the operation for the last weekend in February. I chose Latham or Kizimkazi after research showed it to be a bird sanctuary (with no habitation, which

meant no customs and immigration formalities). Bill made arrangements for a friend to use his boat and service; as skipper in return for cost and fuel for the boat – he also arranged the rental of the Honda E300 and E800 generators which we used. Also from Bill came the mast stays, and stacks for the TA33jr. As my transceiver was in poor shape due to weak tubes, I started scrounging for new ones. K3RLY supplied the tubes and W5KUC provided the vertical, with WA5REU paying the air freight out. So by mid-February everything was moving smoothly. The tubes arrived and G3RIR helped Bill and I get his rig realigned along with our own as all three rigs would be going on the trip (but not G3RIR, as he hadn't a license yet).



On schedule nine days before we were to go came the long-awaited letter giving permission to operate from Zanzibar *provided the East African Posts and Telecoms had licensed us.* I went to Nairobi where 5Z4KL and LW had revived the East African Radio Society's TA33jr from a pile of junk into a serviceable antenna once again. Equipment used and from whom supplied was as follows: W5KUC – 14 AVQ; RSEA – TA3jr: G3RIR – HW100; 5H3KJ – SB100, SB200 generators, masts, and gasoline; and 5H3LV modified HW100, provided camping equipment, packing containers, and misc.

Thanks to our QSL managers, W7VRO for 5H3KJ, CanaD-X VE3ODX for 5H3LV for their continued help in this field. The CanaD-X group are partly if not wholly accredited with getting my HW100 and myself on the air on SSB during my leave

Garth (5H3LV) and Bill (5H3KJ) pose in the uniform of the day of Fungu Kizimkazi, a Zanzibar bird sanctuary isle northeast of the main island, the site of their DXpedition.

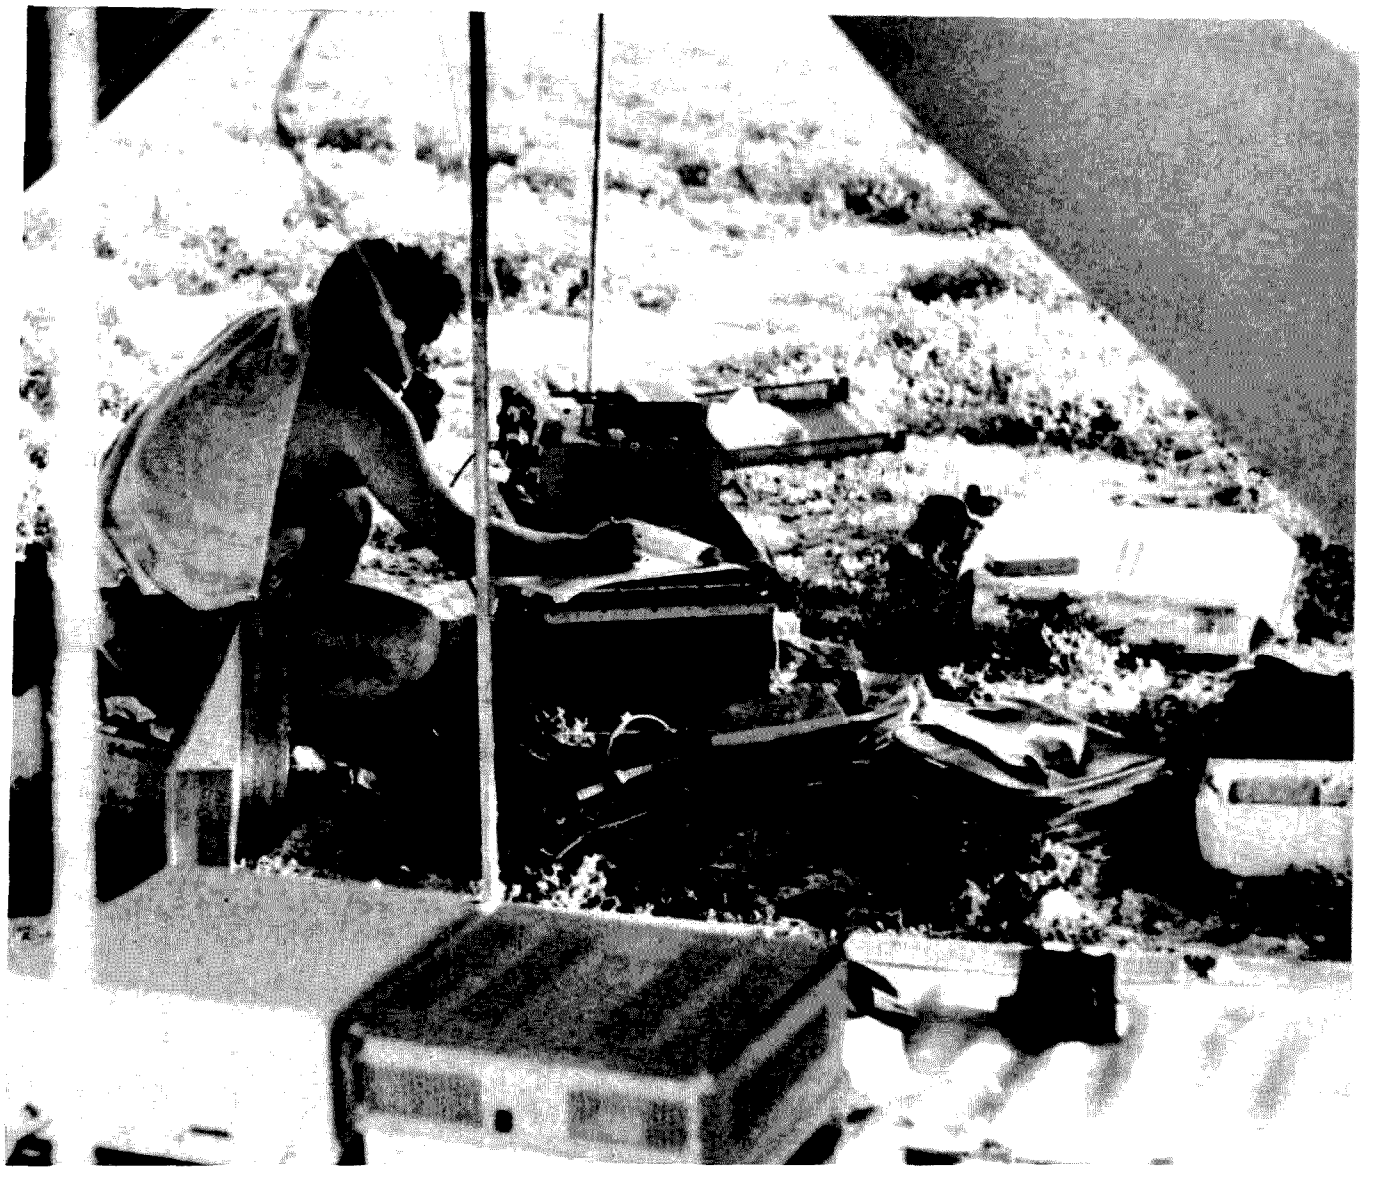
DXpedition

Bill's first attempt to operate 10 and 15 meters had to be abandoned because of watersoaked components in the rig.

period in Canada last May. Such hams as VE3PQ (exVE3CKW), VE3DLC, VE3ACD, VE3NE, VE3HJ, and many others across Canada, whose calls I cannot recall, became responsible indirectly for this operation from Zanzibar. Also W5RBO for his encouragement and financial support.

Now to the more active part which everyone witnessed. We left Bill's at about 9:30 a.m. with all the gear on the VW roof and back seat for the customs jetty where we were to depart at 0700 (GMT). However, the boat was not ready and it was not until 10:45 a.m. that we got the boat to the wharf and loaded it. By 0800 we were under way in the harbor and our passage proved very quiet and comfortable on a smooth sea.

It became apparent early that we were not making the speed the boat was capable of and were informed that this was due to the weight we were carrying. We arrived at Kizimkazi at 1200 already two hours late.



With the large number of birds on the island, the tent served as protection from more than merely falling rain.

By 1320 we had all equipment ashore. One minor mishap occurred during the first landing when Bill and I were not quick enough in getting the boat out of the surf; one wave broke over our stern, getting one packing box wet. On preliminary inspection the equipment seemed to have escaped harm; however, later we learned that the circuit boards in my modified HW100 had gotten wet. This put our second split-frequency rig out of commission before we started.

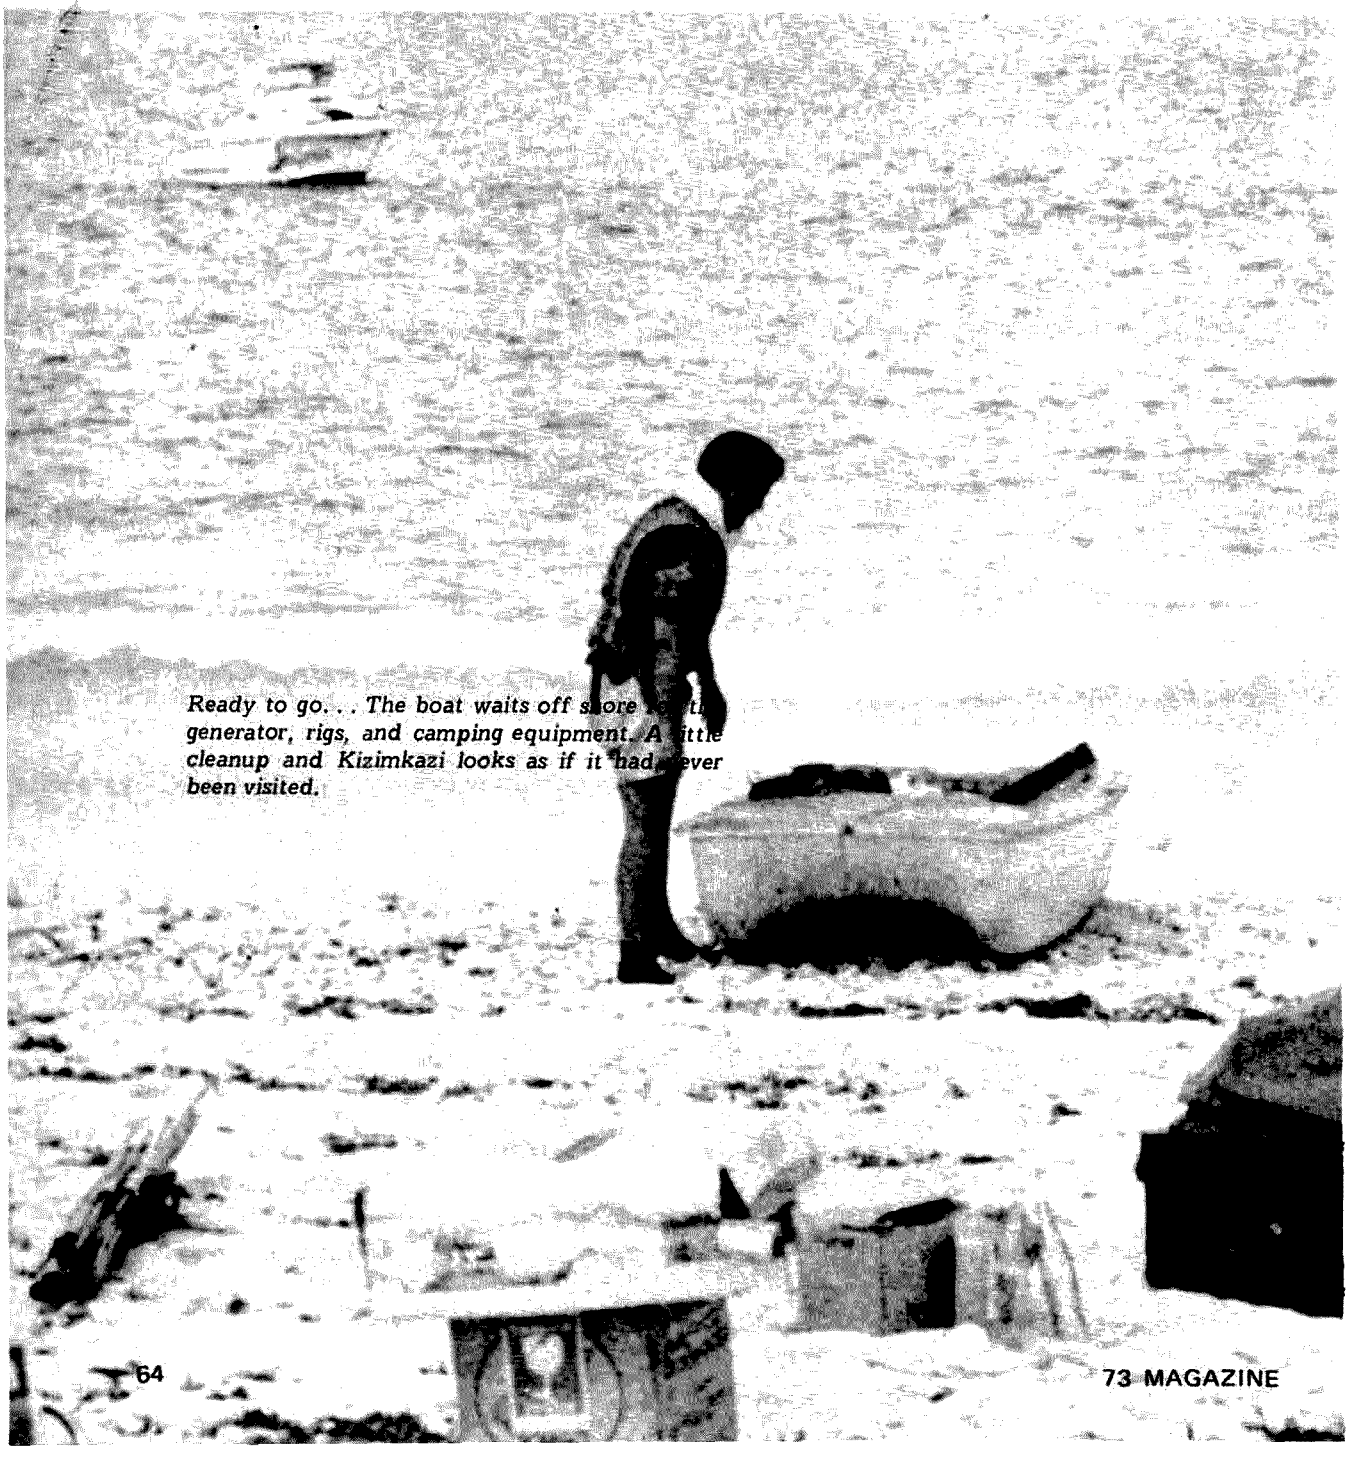
By 1400 the beam was up and Bill was arranging the operating positions while I got the vertical up. At about 1430 we had a quick snack and Bill came on the air on 15 meters. This is where I discovered the water! When I got the other HW100 out and found the power cord from the dry rig wouldn't fit the water-logged one and vice

Garth roughs it by setting up the station outdoors.

versa, we were in trouble. I informed Bill who QSY'd to 20m at 1450, and I started splicing power cables to get the station going. By 1600 I was ready and Bill went up to 15m again; and I finally started operating transceive on 20m.

It was bad right from the start as I could hear stations from every continent calling and not pausing long enough to hear who I had replied to. I was finally forced to work from lists with stations on each continent taking a list to hold for me. I started with the W6s with 5Z4KL serving as "list master." A DJ started a list for Europe, but by 1630 I closed down. I checked the frequency again 45 minutes later – the racket was still over the S9 mark. How they expected to work me under those conditions I don't know.

I believe the action of closing the station may have helped Bill out when he later volunteered to reopen on 15m at 1800, at which time I started operating split-frequency on 20m and stayed there until the band shut down at 0530. Maybe the fact that the 15m band at this time was not open to so many places at once made it a bit easier for Bill to control the frequency. But his technique of frequently moving and his expert handling of contacts served to prove what a first-class operator he is. Bill operated 15m until 0230 when the band closed an unprecedented 3 hours after that band's longest recorded opening previously in East Africa.



Bill took a nap while I made the final run to the finish. It was interrupted when my generator ran out of petrol at 0530.

A few people felt the brunt of our strife to maintain control of our operating fre-

quencies when they refused to heed warnings about tailending – a deplorable yet increasingly common practice – and calling out of turn. I trust these people now realize that such tactics don't endear them to a DX station and least of all a DXpedition. Some of these practices showed up from stations I least expected to hear them from.

Some very sharp teenage hams using 180W rigs got through using some very diligent operating by listening to ascertain just how much of the band I was spanning in relation to what I said I was covering (which was more by 10 kHz on the top side) and then finding a clear spot to transmit and waiting until I started to span near their frequency. These fellows usually got through within three calls while some of the 2 kW wide-spaced monobanders didn't because they staged a howling contest on the bottom few kHz of the band.

The transceiver operators also had a few tricks up their sleeves. They made short

Ready to go... The boat waits off shore with generator, rigs, and camping equipment. A little cleanup and Kizimkazi looks as if it had never been visited.

calls, gave their reports, and mentioned they were transceive. So I gave them an extra second to find me again before I gave their report.

As some of you may know, Bill (5H3KJ) is now QRT and will be heard again as LA6GF. Bill has been a very active ham with over 270 countries to his credit in four years of operating here. He was first licensed in 1956 as LA5GF. I (5H3LV) have been QRT since May 1 this year, after 10 months activity on SSB, having worked 235 countries. I will reappear as VE3EUP on the bands. There is a chance I'll return to this DX spot for a further two years but that is not definite at this time. Since I am the last remaining DXer from here, I shall look forward to the possibility with the added incentive of being the only authorized operator for Zanzibar at this time. If I should return I'll be looking for a rotator for my station quad and an SB200 to boost the signal some more. I shall also endeavor to have an 18AVQ operating at about 50 ft to see if I can do something with the 40 and 80 meter bands. ... 5H3LV ■

STAFF

STUDY GUIDE FOR YOUR GENERAL CL

PART ONE: A STARTING POINT

Following up the tradition we've established in our two previous study courses on the Advanced Class license and the Extra Class license, we've found that it's now time to tackle the General/Technician classes. Since the technical knowledge required for both the General and the Technician class ticket is the same, only one course is necessary.

In case you missed the earlier courses (and if you did, contact the publisher immediately with cash in order to get the collected and bound versions for your reference shelf), here is how we go about it:

Unlike other "Q&A" publications which provide concise answers to the specific questions which the FCC includes on its published "study list" for each class of amateur license, we try to go *behind* the study-list questions and examine the principles on which each question is based.

This makes it much more difficult to simply memorize our answers before taking the exam, but we believe the advantages outweigh this disadvantage (if it really is one). If you study our courses, you'll find that you can still answer the exam questions even if the Commission throws you a curve (as it has been known to do) and includes questions on the real exam which apparently were not even hinted at on the study list. The memorization method won't let you do this.

Because we go so much deeper than most into the theory behind the questions, we must handle the study list in smaller bites. In the past, we've averaged about 5 questions from the FCC study list each month, and the course lasts for as many months as are necessary to cover the material adequately.

In this course, though, we don't expect to average much more than 3 questions each month – because we cannot expect a student working for his General or Technician ticket to have as much technical

background as would someone already eligible to apply for the Advanced or Extra Class ticket. Some months we may take more, and some months less – it all depends upon the questions, and the amount of background necessary.

In this initial installment, we've got to establish a starting point upon which to build all the rest. We'll do so by discussing the theory behind questions 27, 35, 36, and 37 from the FCC study list.

The questions, as published in FCC Bulletin 1035C, are:

27. Define Ohm's Law. How does it relate to resistive and reactive impedance?
35. How do resistors combine in parallel and in series to give total resistance? Capacitors? Inductors?
36. How does voltage division occur across series connected resistors? Capacitors? Inductors?
37. What does it mean to connect circuit elements in series? In parallel?

ASS LICENSE

As we have done in the previous license study courses, we'll re-phrase these questions into new ones which expand to cover the theory behind the FCC's examples.

Our first question, which is ambitious enough in itself to fill a book (and many have been filled with not-too-informative answers to it), will be "What Are Current and Voltage?" In finding answers to that, we'll endeavor to give an accurate definition of not only current and voltage, but what fields and waves amount to and how electricity is propagated.

And in doing so, we'll follow our long-time rule and ban all higher mathematics. To paraphrase Tom Jefferson et al, we hold this truth to be self-evident: That any concept formed by a human mind can be understood by any other human mind, provided only that the concept is framed in terms of other ideas the student already holds. In other words, you don't have to be a genius to understand the ideas a genius has developed, if we can explain them adequately in simple enough terms. To do so, we must rule out any math more complicated than arithmetic and from time to time a touch of the simpler parts of algebra.

When we complete this seemingly-impossible answer, we'll move on to ask "What About Alternating Current?". This will give us an opportunity to look at different ways of connecting elements in a circuit, as well as at the different types of elements themselves.

Think we can do it? Let's dive in and find out.

What Are Current and Voltage? To find out what current, voltage, and the like are, let's go all the way back to the beginning of man's studies of this strange thing called "electricity."

Since ancient times, men have known that some materials such as amber and later glass have the ability to attract light objects to themselves under some conditions. The magnet's discovery is also lost in the mists of prehistory. But until the middle of the 18th Century, both "electricity" and "magnetism" smacked of magic. Little was really known about either.

In 1800, though, an Italian scientist named Volta invented a chemical cell or "voltaic pile" which provided a constant source of electrical energy. Once a laboratory source of electricity was available, many investigators turned their attention to electricity and magnetism – and during the decade from 1820 to 1830 most of the basic laws of electricity were discovered.

Among these was Oersted's observation, in 1820, that any flow of electricity was accompanied by a magnetic field. This observation led the French physicist Andre Ampere to study the forces which resulted from flowing electricity, and Ampere as a result classified electrical effects into "electrostatic" force and "electrodynamic" motion, which he also called "electric

tension" and "electric current." "Electric tension" (now called voltage, for Volta, in this country, but still called "tension" in Great Britain) is a measure of electrostatic force. Electric current, measured in "amperes" (after Ampere), is a measure of electrodynamic motion.

Michael Faraday discovered, in 1831, that motion of a magnetic field would "induce" a flow of electric current in a stationary conductor. This completed the symmetry of electrical and magnetic effects, but the actual manner in which electricity and magnetism were related remained unknown.

Many ideas were put forth, but none could be proved to actually be true. The most lasting, probably, of these ideas involved the "line of magnetic flux." This "line" survives today as a part of basic theory as taught in engineering courses – but most authorities now believe the line to be imaginary, rather than an actual thing.

Since the work of Oersted, Ampere, and Faraday (as well as others less well-remembered) had made the relationships between electricity and magnetism obvious, many investigators attempted to express the rules of the relationships. None succeeded until James Clerk Maxwell, in 1865, published his "Dynamical Theory of the Electromagnetic Field." While the theory itself has not yet been (and probably cannot ever be) proven beyond doubt, it *has* successfully predicted, and continues to predict, all electromagnetic actions within its intended range, and is today accepted as a true working theory

Maxwell's Equations, which define the theory mathematically, are required knowledge for any electrical engineer, and once they are understood they provide adequate explanation of all electromagnetic effects yet observed.

The actual equations are not simple. Maxwell himself required 20 separate equations in 20 variables to express them. Their reduction by later workers to the four Equations taught today has added a requirement for knowledge of integral calculus, differential equations, and vector analysis, since these were the tools used to reduce the equations.

The theory, taken apart from the Equations, is elegantly simple, though, and not too difficult to understand provided we don't ask a few critical questions which it cannot give us answers for. It begins with a single assumption – that the space around electric or magnetic objects contains (to quote Maxwell) "matter in motion, by which the observed electromagnetic phenomena are produced."

From this assumption, Maxwell went on to define "the electromagnetic field" as being "that part of space which contains and surrounds bodies in electric or magnetic conditions." He was careful to point out that this could be as complete a vacuum as could be obtained anywhere, but that there would always be "enough of matter left to 'receive and transmit the undulations of light and heat."

Because the transmission of light and heat was not greatly changed when transparent objects such as glass were substituted for the best available vacuum, he concluded that the "undulations" must be occurring in some form of matter which was not directly observable. He called this unknown form of matter "an aethereal substance," which later workers shortened to "the aether" or "the ether"; the question whether "the aether" exists is one which Maxwell's theory cannot answer, because the assumption that it *does* exist is the basis on which the theory is founded.

Later experiments by Michelson and Morley cast doubts upon the existence of the aether, and for many years now the label "aether" has been out of style. Today, we know this unknown medium as "the space-time continuum," but for our purposes here the change is more one of name than of basic concept. Therefore we will temporarily ignore the work of Michelson, Morley, and Einstein, and for the moment think only in terms of Maxwell's "aethereal substance." By doing so, we can get an adequate – and accurate – picture of how voltage, current, and charge operate.

"Now the energy communicated," wrote Maxwell, "must have formerly existed in the moving medium." He based this conclusion on the observed fact that a detectable time delay exists between the energy's departure from its source and its arrival at its destination. He then borrowed knowledge from studies of the familiar motion of objects, to conclude that while the energy was in the unknown medium, it must have been "half in the form of motion of the medium, and half in the form of elastic resilence."

From this chain of reasoning, he drew the conclusion that the parts of the unknown medium "must be so connected that the motion of one part depends somehow upon the motion of all the rest," and at the same time "the connections between the parts must be capable of elastic yielding" of some sort, because otherwise the communication of motion from one part to any other would not require any time – and both heat and light, though fast, do not travel instantaneously.

Maxwell then reworded this conclusion into a description of the significant properties of his unknown aethereal medium; he said that it was "capable of receiving and storing up two kinds of energy, namely, the 'actual' energy depending on the motion of its parts, and 'potential' energy, consisting of the work which the medium will do in recovering from displacement in virtue of its elasticity."

These two kinds of energy, "actual" and "potential," correspond exactly to the "kinetic energy" and "potential energy" of ordinary objects. They also, as it happens, correspond exactly to the "electrodynamic" and the "electrostatic" effects named by Ampere.

The equations Maxwell developed provide the actual descriptions of these properties, based on the observations reported by earlier investigators. Engineers need them. They are not necessary for an understanding of "how" voltage, current, and charge work.

According to the theory as developed by Maxwell, the induction of current in a stationary conductor by a moving magnet, or in a conductor moving past a stationary

magnet, is a result of the same force involved in transmission of motion from one part of the medium to another. It is, then, an effect of "actual" energy as contrasted to "potential" energy.

If the conductor does not form a complete circuit, no current can flow. Instead, a voltage or potential appears across the ends of the circuit. Should the circuit be completed, current will flow and the voltage will vanish – but so long as the circuit remains open, current will be zero and the voltage will be present.

This voltage or potential represents a transformation of energy from its "actual" state of motion into the "potential" state of storage.

This transformation of energy from "actual" to "potential" is a cornerstone of Maxwell's idea, and his summation of it is the feature which gives his theory its great power to explain and predict all electromagnetic effects.

"The propagation," he wrote, referring to the propagation of light and heat through his undefined medium, "consists in the continual transformation of one of these forms of energy into the other, alternately."

That is, he conceived of the transmission of electromagnetic energy as an endless process of transforming energy from a state of motion to a state of storage, and back to motion.

Figure 1 shows how you can illustrate this principle with a row of pennies or other coins, by lining them up in a straight line so that each touches its neighbor on either side. If you strike the penny on one end with another coin, and if the motion of the "striker" coin is in line with the other coins, the penny at the other end will fly off the line but none of those in between will move visibly.

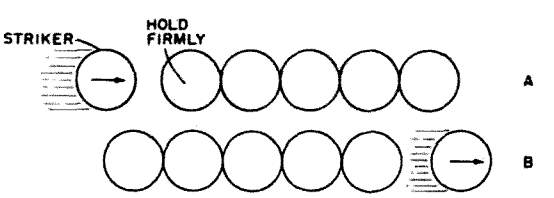

Fig. 1. Simple experiment with rows of coins illustrates motion-compression-motion cycle which is basis of both electric current and magnetic effects. If coins are lined up as shown at A, with one held or clamped firmly, and line is struck end-on by another coin, coin at far end of line will move off of line but those in between will not move visibly. Text explains why.

What actually happens in this demonstration is this: The energy of motion of the "striker" coin compressed the first penny by a microscopic amount at the moment of impact. As soon as the impact force had all been transformed into a compression, then nothing was holding the first penny compressed, so it sprang back into its original shape. This motion of rebound, in its turn, compressed the penny next to it, and so the motion was carried down the line of coins, one penny at a time, by an alternate series of motions and compressions.

Exactly the same sort of thing, said Maxwell, goes on to produce the propagation of electromagnetic energy. And since by his theory every "electric or magnetic body" is surrounded by his aethereal medium, and present theories hold that all physical matter is electric in nature, it follows that electromagnetic energy can be propagated in this matter throughout all parts of space which are occupied by any kind of physical matter.

Actual physical matter divides into two broad classes known as "conductors" and "insulators"; the defining property which separates these classes is that conductors permit the flow of electric current within themselves, and insulators do not.

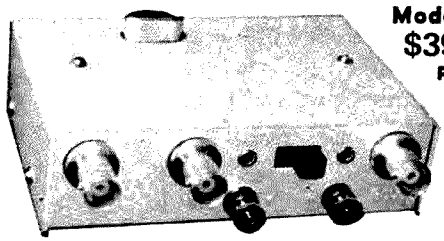
It is generally believed that the difference depends upon molecular and crystalline structure, and that conductors contain electrons which are free to move anywhere within the boundary of the conductor without restraint, while insulators have few or no "free" electrons. It is important to keep in mind that these "free" electrons which are involved in the flow of electric current are a part of the conducting material, and are *not* associated with the "aethereal substance" which provides a means for propagation of electromagnetic energy.

What happens, according the present theories, is that the energy transformations going on in the "aethereal substance"

impart some of their energy to the free electrons. The exchange is two-way in nature, so that free electrons in motion lose some of their energy to the unknown medium. We say that such energy is "lost by radiation" and the whole point of a radio transmitter is to "lose" as much energy as possible by radiation, in order to communicate over long distances.

When the free electrons of a conductor receive excess energy, they move in the direction indicated by the energy. Their motion is, as we shall soon see, by definition the flow of an electric current.

If the conductor forms a complete circuit, the free electrons can move indefinitely in the same direction as long as they maintain their energy. The energy is gradually lost, however, by being released back to "the electromagnetic field" and by collision with "bound" electrons and other atomic particles in the conductor.



When a free electron approaches a bound electron, the bound electron is repelled and attempts to get out of the way. The bound electron, though, is an integral part of an atom, which in its turn is fixed into place in a molecule, and it cannot get out of the way unless the whole molecule moves. To move a molecule takes energy, and molecular motion is also known by the more common name "heat."

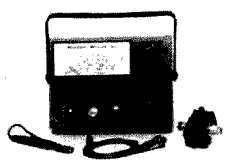
This transformation of electrical energy of motion into the molecular motion of heat is called "resistance," and all normal conductors have resistance in varying amounts.

If the circuit is not complete, the electrons can move only a limited distance before they reach a boundary which stops their motion. The motion-compression-motion cycles must then halt in a state of compression or "storage."

The "storage" of energy occurs not in the conductor, but in the insulating medium which keeps the circuit open. Although the electron theory of matter was still several decades in the future when Maxwell developed his theory of fields, he considered that "the electricity" in each molecule of the insulator was forced to one side or "displaced" from its normal position by the "potential" energy, and re-

THE BEST
2 METER
CONVERTER

Model 407
$39.95
ppd.



144-146 MHz in. 28-30 MHz out
or 146-148 MHz with a second crystal
Available at $4.95 each.

A full description of this fantastic converter would fill this page, but you can take our word for it (or those of thousands of satisfied users) that it's the best. The reason is simple—we use three RCA dual gate MOSFETs, one bipolar, and 3 diodes in the best circuit ever. Still not convinced?Then send for our free catalog and get the full description, plus photos and even the schematic.
Can't wait?Then send us a postal money order for $39.95 and we'll rush the 407 out to you.
NOTE: The Model 407 is also available in any frequency combination up to 450 MHz (some at higher prices) as listed in our catalog.

mained there until either the removal of the potential energy, or the completion of a conducting circuit around the insulator, permitted the displaced electricity to resume its normal position.

This "displacement" of the internal structure of an insulator under pressure of applied voltage is what we now call "charge." Since the electron theory was developed, we consider that the displacement occurs by a bunching of the electrons within the insulating material, and, if necessary, a physical distortion of the material's molecules to align most of the electrons on one side.

We measure "charge" by a unit called the "coulomb," which is approximately equal to the displacement of 6,280,000,000,000,000,000 electrons. An insulator which has one coulomb of charge has that astronomical number of electrons displaced to one boundary, we believe. (But no one has yet counted them, because the electron is too small to see and we cannot locate its position accurately by any means.)

When a conductor permits the potential energy of the charge to convert itself back to actual energy of motion, all of these electrons return to their normal positions, and we call the resulting flow of electrons a "current." The unit of current is the ampere, and one definition of an ampere is a flow of one coulomb of charge in a time of one second. time. Current is an electroDYNAMIC effect, while charge can exist without motion, and so is electroSTATIC in nature.

Charge is a measure of quantity, similar in many ways to the "pint" or "gallon" of liquid measure. A given amount of charge may, if released from its static state, produce any amount of current, depending upon how long the flow lasts – in exactly the same way that a gallon of water may drip through a tiny hole over a period of hours, or may be emptied by overturning the bucket in a matter of a fraction of a second.

The other fundamental electric unit, the volt, is a measure of potential, tension, or pressure. Though the volt is a static unit, it is like the ampere in that one coulomb of charge may be stored at any voltage.

What determines the voltage for any given quantity of charge is the electrical capacity of the insulator in which the charge is stored. "Electrical" capacity is not quite like "physical" capacity; the thicker the insulator, all other things remaining equal, the smaller its electrical capacity, but the greater the surface area the larger the electrical capacity will be. This comes about because charge is stored *only* at the boundaries between the insulating material and the conductors. The farther apart these boundaries are, the more pressure is required to keep all electrons displaced; the larger the area of each boundary, the more room for charge.

To distinguish between physical capacity and electrical capacity, we call electrical capacity by the special name "capacitance". The voltage associated with any particular amount of charge depends not only on the amount of charge, but upon the capacitance in which the charge is stored. The unit of capacitance is the "farad", for Faraday, and one definition of a farad is that capacitance which will store one coulomb of charge at a potential of one volt.

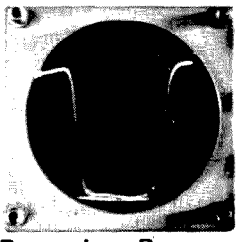
Other definitions make use of specified measurements for area, separation of the surfaces, and kind of insulating material, so that we can reverse this definition of a farad and make it a definition for the volt – that pressure (or the potential energy) of one coulomb of charge stored in a one-farad capacitor. Two coulombs of charge in the same capacitor would produce a potential of two volts, and so forth.

The units of "charge" and "potential," then, as well as that of "capacitance," describe electrostatic effects or "static electricity," while the unit of "current" describes an electrodynamic effect. When a circuit includes either a chemical cell or a generator which converts motion to electrical energy, the electrostatic units of potential and capacitance may still take part in the circuit, but the flow of current is the essential item.

In today's world, most authorities don't use Maxwell's own names of "actual

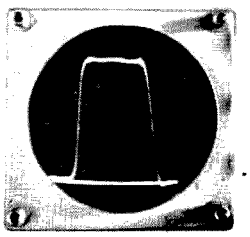
energy" and "potential energy" to describe the motion-storage-motion cycles. Instead, the component which Maxwell called "actual" and which is the "motion" part of the cycle is called "the magnetic field" and the component which Maxwell called "potential" and which is the "storage" or "displacement" part of the cycle is known as "the electric field."

Either of these fields can, apparently, exist apart from the other so long as no motion is introduced. A permanent magnet has its own magnetic field, but if it is at rest no electric field surrounds it. Similarly, a charged capacitor contains an electric field, but if no current is permitted to flow no magnetic field is associated with it.



Introduction of motion, whether it is the physical motion of the field with respect to its surroundings, the physical motion of the surroundings with respect to the field, or the electromagnetic motion produced by providing a complete circuit and thus permitting discharge of an electric field, results in the presence of both kinds of fields. Whether the motion causes the field to exist, or the field causes the motion, is not really a matter worth worrying about. Sometimes it seems to be one way, sometimes the other, and in many cases nobody can determine which is cause and which is effect.

At this point, we have defined "charge" as the displacement of a specific number of electrons, "capacitance" in terms of physical distances, "current" in terms of change and time, and "potential" in terms of charge and capacitance.



While we still have no knowledge of the *nature of that "aethereal medium" which* is known as "the electromagnetic field" – in fact, no one has much more knowledge of its nature than that set forth by Maxwell in his original description, when he wrote that the electromagnetic field is "that part of space which contains and surrounds bodies in electric or magnetic conditions" – we *do* have an explanation of a possible means by which voltage and current are produced and propagated.

And, as it turns out, that's all we really need in order to do anything we desire in electronics.

Now that we know more than we really wanted to about charge, voltage, current, and capacitance, let's look at some other factors involved in the flow of charge or "electricity."

Just before we began examining the nature of voltage, we saw in passing that a given amount of charge may, upon being permitted to flow from a static state, produce any amount of current depending upon how long the flow lasts.

At that time, we compared it to the tiny drip of a gallon of water which might take hours, and to the sudden overturning of a gallon bucket. We did not, however, look for the factor which controls how long a flow of current may last, starting from a given amount of charge.

Such a factor does exist, of course, and we've already made its acquaintance. It's "resistance," caused by interaction between free and bound electrons in any normal conductor.

The unit of resistance is the "ohm," for Georg Simon Ohm, who first formulated the law which relates voltage, current, and resistance. Ohm's Law is of such fundamental importance to all electrical work that it comes as something of a surprise to discover that Ohm formulated the rule simply as a by-product of his studies into the effects of heat upon resistance, and in his original description, did not express the law in the formula which today bears his name. The familiar formula is the invention of Maxwell, who included the law as one of his 20 equations.

We saw, when looking at the qualities which separate conducting materials from insulators, that conduction is accomplished by "free" electrons, which are free to migrate from place to place as contrasted to "bound" electrons which are held firmly in place in an atomic structure. We also saw in that study that free electrons always lose some of their energy as heat, because of interaction between free and bound electrons.

This interaction within any normal conductor is the major factor limiting current flow within that material. It, in turn, depends upon the number of free electrons within the material, which is determined by both the material itself and by the physical size of the conductor. Different materials have different ratios of free to bound electrons, and the larger the conductor the more free electrons will be available within any one cross-section of it.

The more free electrons a material contains, the better that material is as a conductor. We say it has low resistance. Silver has the lowest resistance of any normal conductor, but copper is almost as good a conductor and costs considerably less. For this reason, copper is the most widely used conductor.

Some materials have few free electrons, although still enough to be classed as conductors rather than as insulators. The resistance of such materials is high. One such material is carbon. Another is the nickel-chromium alloy known as "nichrome".

True resistance, or "pure" resistance to use a jargon term, is the conversion of electrical energy to heat. Many effects other than true resistance can also cause energy to be "lost" from a circuit, though, and most usually these effects are also known as "resistances." One example is the radiation of energy from a circuit such as a transmitting antenna.

The difference between true resistance and these other effects which may also be labelled as "resistances" is that true resistance produces heat while "imitation" resistance does not. The "radiation resistance" of an antenna, for instance, has no heat associated with it; the energy is radiated instead.

In a complete circuit with steady current flow – a "direct current" or "DC" circuit – the potential, current, and resistance are all related by Ohm's Law, which states that the potential in volts is equal to the product of the current in amperes multiplied by the resistance in ohms. Stated in its most familiar form, $E = IR$, where E is voltage, I is current in amperes, and R is resistance in ohms.

If we know any two of these three quantities, the third is determined by Ohm's Law. Using high school algebra we can rearrange the formula to find resistance if voltage and current are known ($R = E/I$),

WHEN IT COMES TO ANTENNA SYSTEMS... IS YOURS

or current if voltage and resistance are known (I = E/R).

A number of memory aids have been developed to help students remember Ohm's Law. One used by our staff is the simple word "ear," which is what comes out if you try to pronounce "E-IR" and consider the "=" to be silent. If you're handy at algebra this is all you need, because it's not difficult to turn the formula around into the other two versions.

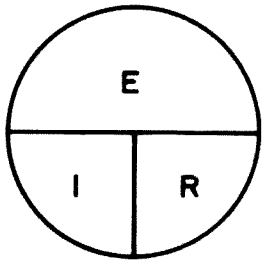

Fig. 2. This simple picture may help you remember Ohm's Law. E stands for voltage, I for current, and R for resistance. To get formula for calculating any one if you know the other two, cover the unknown and the picture shows you the right formula. For instance, covering R gives E/I.

Another involves an Eagle, an Indian, and a Rabbit. The Eagle flying above the prairie sees both the Indian and the Rabbit below him, so E = IR. To the Indian, the Eagle is above the Rabbit; I = E/R. To the Rabbit, the Eagle is above the Indian; R = E/I. Figure 2 shows still another which uses a circle divided into one half and two quarters to provide the same illustration.

Although these simple versions of Ohm's Law are those most widely used, it's necessary to keep in mind that they apply only to DC circuits. If the current is changing, modifications become necessary. A chemical battery provides DC. A simple generator, however, produces current of quite another kind which we will take up a little later.

With voltage, current, charge, resistance, and capacitance all defined, we have completed answering our question. There's still one more major electromagnetic effect, but it does not apply when current flow is steady – so we will wait a bit to study it.

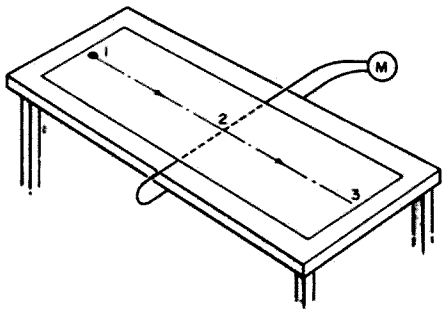

Fig. 3. Principles of converting motion to electric current are shown here. Magnet at 1 is moved along line shown, crossing wire. Motion of magnet induces flow of current in wire. See text for more detail.

What About AC? Just a couple of paragraphs back we mentioned that while a chemical battery provided DC, a simple generator gives current of quite another kind. Let's look into this a little deeper.

We saw earlier that according to Maxwell's theory, a flow of current is associated with any motion of a conductor within a magnetic field.

Assuming that the magnetic field is of constant strength, then the faster the motion the greater the current. If the polarity of the field is reversed, the direction of current flow will also reverse.

These facts provide a method for converting mechanical motion into electrical energy, by using a magnet and a conductor, one of which remains stationary while the other is moved.

Figure 3 shows an impractical example to illustrate the idea, before we go on to more practical techniques. Let's assume that we have a wire conductor stretched flat on a large table-top and covered with a thin sheet of paper to provide a smooth surface. Let's assume also that we have a small, powerful permanent magnet, which we are free to move across the table.

Let's start at Point 1, well away from the wire, and move the magnet at a constant speed up to and across the wire at Point 2, continuing on away from it to Point 3, and at all times measuring current in the wire.

As we do so, we find that the instant the magnet begins to move a small amount of current flows. At the beginning, the flow increases rather slowly, because during any tiny fraction of a second the distance from magnet to wire undergoes little change so long as the distance is large.

For example, if Point 1 is 100 in. from the wire, then if the magnet moves at a steady rate of one inch per second, it will move the 1/10 inch from 100 to 99.9 inches in the first 1/10 second. The change in distance is only about 1/10 of 1%. Since "speed" is a measure of distance moved in a given time, the effective speed is low.

But when the magnet is only 10 inches from the wire, then in the next 1/10 second it will move the 1/10 inch from 10.0 to 9.9 inches, which is 1% of the distance or 10 times as much relative motion as at point 1. The effective speed is thus 10 times greater than at the start, and current will also be 10 times greater.

When the distance is down to only ½ inch, the 1/10 inch moved in 1/10 second is such a large part of the total distanct that it's difficult to decide just how much faster the effective speed is, but it must be at least 20 times greater than at the 10-inch distance or 200 times greater than at the start.

Current flow, likewise, is great. In fact, the current intensity reaches its peak as the magnet passes over the wire. Once the magnet has passed Point 2, it's moving away from the wire rather than toward it,

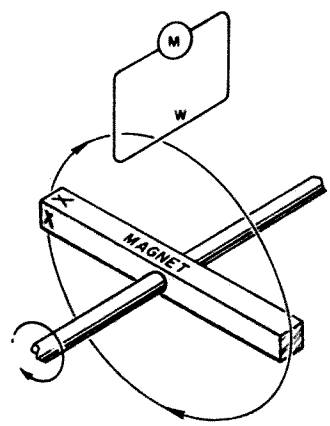

Fig. 4. This sketch shows the simplified generator we use to illustrate the nature of ac and how it gets that way. It's just a bar magnet on a rotating shaft, with one wire just outside the path of the magnet poles. As magnet rotates, currents are induced in wire. Intensity of current depends upon shaft position at each instant as discussed in text.

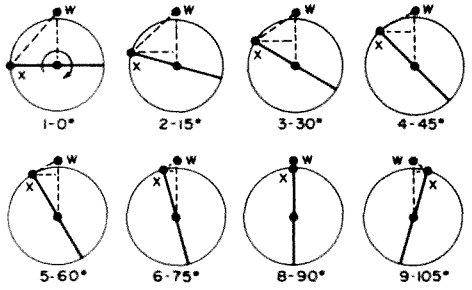

Fig. 5. "Snapshot" sketches of our simplified generator, seen end-on, as it would appear at eight points from 0° to 105° of rotation. All rotation here is clockwise. Key factor is distance from nearer pole tip to our wire, indicated as distance XW. Triangles (dotted lines) help us to calculate this distance for each position of magnet.

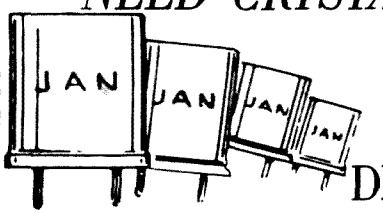
and so the "effective motion" is becoming smaller at exactly the same rate that it increased during the approach. This means that effective speed is decreasing, and so must be the current flow.



The straight-line or "linear" motion we've used in this example isn't very practical for normal use. Rotary motion is much simpler to handle in actual machinery. Practical generators put either the magnet or the conductor on a rotating shaft, and the other half goes on a stationary frame known as the "field" close by.

For our illustration, let's put the magnet on the shaft, and keep a single wire just outside the circle described by the rotating tip of the magnet. We'll use a bar magnet, with its two opposite poles, to make the illustration a bit more practical. Figure 4 shows the arrangement.

When we change from "linear" to "rotary" motion, the way in which effective motion varies with time undergoes a few changes of its own. Let's try to see just what happens; to do so, we'll have to use a little geometry – but very little. All we have to accept from the geometers is the rule for determining the length of one side of a triangle, if we know the other two sides.

Figure 5 shows several successive "snapshot" sketches of our generator, seen end-on, as the shaft turns through a little more than ¼ of a full revolution. Starting at a point which we arbitrarily called "0°," the snapshots show the relation between mag-

net and wire at 15-degree intervals as the shaft rotates.

You can see that the distance "XW" from magnet to wire is the "effective distance," and the "effective motion" during any period of time must be the change in this distance. "Effective speed" must be related to the effective motion.

If the total length of the magnet is 20 inches, then the radius of its circle of rotation will be 10 inches. At the time of our first snapshot, the magnet pole is as far from the wire as it can get without the other pole being nearer. This happens when the magnet and the line from wire to shaft form a right angle. Because of this, distance XW is the hypotenuse of a right triangle, and each of the other sides is 10 inches long. Applying the geometry at this point, we find that distance XW is 14.142 inches.

At the second snapshot time, XW has become shorter. It's down to about 12.1752 inches. By the third, it's down to 10 inches, and by the fourth, to about 7.65 inches.

That is, during the time between the first and the second points the effective motion was 1.97 inches, between the second and the third the motion was 2.18 inches, between the third and the fourth, 2.35 inches, and so on. Just as in the case of linear motion, the motion during a fixed period of time becomes larger and points X and W approach each other.

The change in effective *speed* is also important, though, and this is where much of the difference comes in. Unlike the change in effective motion, the change in speed is greatest when X and W are furthest apart.

The calculations to determine this are much too much arithmetic to go into here (in fact, they are so much arithmetic that we fudged and gave the problem to a computer – Fig. 6 is the table of results it gave us back), but when we do them we find that the relative change in speed between snapshots 2 and 3, for instance, is 0.2083, while from 3 to 4 it is only 0.1711 and from 4 to 5 it's down to 0.1310. The change becomes smaller until X passes W, then gets larger again.

In Fig. 6, the column headed "SPEED CHANGE" shows the continual change of effective speed as the shaft is rotated.

Students who have been exposed to trigonometry may recognize the triangles dotted into Fig. 5 as bearing some resemblance to the "unit circles" used to define and illustrate the various trig functions.

As it happens, the resemblance is so great that it turns out that effective speed is related to the sine function of the angle through which the shaft is turned.

Now that we've seen how the effective motion changes with changes in shaft position, let's perch ourselves right on that wire at Point W and watch the magnet poles as we rotate the shaft.

When the shaft rotates, each pole in turn "rises" over the "horizon" formed by the rim of the circle, as in snapshot 1 of Fig. 5. It moves rather slowly at first, but picks up speed rapidly.

As the pole approaches us, its effective speed continues to increase, but the

acceleration slows down. During the final part of the approach, its speed is great but almost constant. It passes us at a rather rapid rate, and immediately begins to slow down as it curves away.

The deceleration is slow at first, but as speed becomes less and distance increases, the rate of deceleration increases in an exact mirror of the acceleration rate during the approach. Finally this pole disappears over the "far horizon" just as the opposite pole "rises." This succession of pole-passages continues so long as the shaft is rotating.

The result, in the circuit of which our wire is a part, is a continual reversal of current flow as one pole "sets" and the other "rises." At these instants, current flow in the wire is zero because the opposing magnetic fields of each pole "cancel out." In between these "zero" points, the nearer pole's field takes over, and current flow either rises to a positive peak or falls to a negative peak, as each pole in turn flashes past the wire.

Because the effective speed of the magnetic field, and the resulting intensity of current flow, is associated with the sine of the angle through which the shaft has turned, we call the resulting current a "sine wave."

Because the current alternates in direction twice during each full revolution of the shaft, as the two opposite poles pass, we also call it "alternating current" or "ac."

Early experimenters had no practical use for ac; the reversals of polarity cancelled out many of the effects in which they were most interested. To get rid of it, they put a rotating switch called a "commutator" on the shafts of their generators, to reverse the connections between the conductor and the outside circuit whenever the current direction reversed and thus cancel out the effect of the current reversal.

They also used many windings, rather than just one conductor, so that at any one instant they were taking current only from the conductors which were at that time generating peak current.

DUAL GATE MOSFET

PRE-AMPS

to 175 MHz. $21.95 ppd.
to 300 MHz. $25.95 ppd.

NEW FOR 1970!
The above models now have rf gain control.

For 300 to 470 MHz
See Model 202 in our catalog.

- Available from 5 MHz. to 450 MHz. Bandwidth is approximately 3% of frequency.
- Voltage gain 30 to 40 DB depending on frequency.
- Two Dual Gate MOSFET amplifier stages with each having a tuned input and tuned output. Each Dual Gate MOSFET is actually an integrated cascode circuit thus giving you 2 cascode circuits equivalent to 4 triodes.
- Exceptionally low noise (2.5 DB at 175MHz.), greatly reduced cross modulation and 10 times the dynamic range (signal handling capability) of the best bi-polar transistors. Also superior to preamps using junction FETs and Single Gate MOSFETs.
- Internal connections for high impedance AGC or manual gain control if needed.
- Type BNC input and output receptacles for minimum loss at UHF. Standard impedance is 50-75 ohms.
- Carefully tuned at our laboratory with sweep generator and oscilloscope for the best bandpass characteristic.
- Full wave UHF diodes protect input transistor.
- Operates on 6 to 16 volts DC, 5 to 15 Ma.

New York City and State residents add local sales tax.

Only recently has the "alternator," or simple generator such as we've described here, come into popularity. In a practical alternator, the magnetic field is produced by a field coil rather than by a permanent magnet, and a multi-turn output winding rather than a single conductor is used, but the principles remain the same.

One important factor necessary to talk about ac, which was not required with dc, is a measure of the number of times each second that the current changes direction. The older standard for this was the "cycle per second," with one cycle being the result of one full revolution of the shaft in our simplified generator. That is, one cycle includes a positive peak, a negative peak, and two zero crossings (one in each direction). A cycle may begin at any point on the waveform, and when that point has been reached the next time from the same direction, the cycle is complete.

Recently, the U. S. adopted an international standard of frequency called the "hertz" in honor of Heinrich Hertz, who was the first person to test Maxwell's theory by transmitting and detecting radio waves. One hertz is the same as one cycle per second.

Whether measured in hertz, or in cycles per second, the quantity so measured is called "frequency" because it is a count of the frequency with which the current alternates.

Closely allied to "frequency," but not identical, is the term "wavelength." A wavelength is the distance travelled by the energy during the course of one cycle, to put it roughly.

If the current flow moves at the speed of light, then wavelength in meters is equal to 300,000,000/frequency in hertz. This comes about because the accepted figure for the velocity of light is 300,000,000 meters per second. If, for example, an ac wave is alternating at a frequency of 50,000,000 hertz, then in one second it will undergo 50,000,000 cycles, and these 50 million cycles will be able to travel for 300 million meters in that time. Each of them, then, must stretch over a distance of 300/50, or 6, meters, so the length of each wave, or wavelength, is 6 meters.

If frequency is expressed in megahertz or megacycles, the conversion is simplified and becomes wavelength in meters = 300/f where f is frequency in Mc.

In dealing with any ac circuit, it's essential to remember that what makes it ac is the fact that the current's direction reverses as time passes (which requires current intensity to change with time, as well). This fact makes ac behave very differently from dc in many instances. One of the differences shows up when we try to measure ac voltage or current, and we'll look at that in a little while. Another difference brings us back to that one remaining major electromagnetic effect, which we postponed looking at in the previous discussion. It's time, now.

We have seen, with the help of Maxwell's theory, how a flow of current is always associated with a magnetic field, and have also learned that a magnetic field in motion is always associated with either a current (if a complete circuit is present) or a charge (if no complete circuit is available). It follows, with a little thought, that if a current is flowing in a circuit and anything changes the flow of the current, the associated magnetic field must change – and this resulting change must, in and of itself, be associated with a "secondary" or "self-induced" current which is completely different from the original current.

As it happens, this "self-induced" current is of such a polarity as to oppose the change of original current which called it into being in the first place, which means that electric current flow has a property very similar to that called "inertia" in ordinary moving objects. This property tends to keep any current flow constant, and opposes any change.

Because it is produced by "self-induced" currents, this inertia-like property is called "inductance," and it is measured in a unit known as the "henry." The usual definition of inductance involves the "line of magnetic flux" which we saw much earlier is probably imaginary rather than real. By this conventional definition, inductance is a measure of the number of lines of flux which encircle the total

current ("linkages"), per ampere of current. The henry is defined in this manner as the number of linkages divided by current in hundred-millionths of an ampere.

Although this definition leads to some complicated mental corkscrews, when one attempts to figure out how to count the number of imaginary lines in an unbounded region of space, it's probably as good as any other. In actual practice, inductance is measurable only by its effect in a circuit.

The "true" inductance of any specific inductor depends not only upon the material, shape, and size of the inductor, but also upon the amount of current flowing in it, the rapidity with which current flow changes, the number, size,, conductivity, shape, and proximity of all surrounding objects, and several other factors.

With so many uncontrolled variables in the picture, any measurement or calculation which claims to give "true" inductance is more than somewhat open to doubt!

The most important fact to keep in mind about inductance is that it represents an effect which impedes any change of current flow in a circuit. The more rapid the change, the greater the effect. Similarly, the greater the absolute flow, the greater the effect. Once a current flow becomes steady, however, its associated magnetic field is fixed and does not move. As a result, the "self-induced" current disappears, and inductance is no longer a factor.

Thus inductance applies to dc circuits only during the small periods of time when current flow is changing. Since current flow in an ac circuit is continually in a state of change, inductance is an important factor in the functioning of ac circuits.

Now let's look at some of the differences in measurement between dc and ac.

In most dc circuits, measuring voltage or current is relatively simple. Both voltage and current are steady as time passes, and all we must do is determine the intensity.

But in an ac circuit, current is constantly reversing its direction and voltage follows right along (though in some ac

circuits there may be a time delay between current and voltage). If we want to determine intensity, we must also determine just when to take the measurement.

Because the current is zero at two points in the cycle, at a positive peak at one point, at a corresponding negative peak at another point, and at all other points is balanced by a corresponding value of opposite polarity, if we simply take the average intensity over a complete cycle, both current and voltage will average out to zero regardless of the peak values of either.

This is exactly what happens when we try to measure ac with a dc meter. The meter faithfully averages values over complete cycles and indicates zero, even though the actual energy may be enough to burn the meter out.

One way of measuring ac might be to look only at half of the cycle, and take the average over that half-cycle. Then we could multiply the reading by two to account for the other half-cycle, or simply ignore it. This kind of measurement is sometimes made, and it's called the "average" value.

Unfortunately, the voltage and current readings we get by "average" measurement of ac don't correspond very well in practice to dc readings. We expect a 110-volt light bulb to have the same brightness on 110 volts of ac that it does on 110 volts of dc. If our 110 volts of ac is based on an "average" reading, the bulb will be much brighter on the ac.

It would be nicer to have a method of measuring ac which would give readings directly comparable to dc values. Such a method exists; we can measure the amount of heat generated by ac in a resistor, and find out how much dc is necessary to produce the same amount of heat.

Such a value is known as the "effective" value of the ac, and also as the "rms" value. The "rms" stands for "root mean square," and refers to a mathematical technique used to convert other kinds of measurements to effective values.

When ac voltage or current is not labelled as being in some other method, the effective or rms value is understood. Thus the 115 volts of the ordinary wall plug is 115 volts rms; the "average" voltage of this same plug is just under 103.

Sometimes the easiest way to measure ac is to measure intensity from zero to either peak. This is known as "peak" voltage, and its value is 1.414 times the rms value for the same signal. "Peak" voltage of 115-volt household power is about 163 volts, which is why some simple power supplies produce about 150 volts of dc from a "115-volt" input. It's "peak" voltage that you feel when you touch a defective appliance and get shocked.

In a few cases the most meaningful measurement is from one peak to the other, or "peak to peak" readings. With a sine wave signal, this is 2.83 times the rms value or twice the peak reading; with other ac waveforms there may be no way to relate readings. Peak-to-peak values are important because they represent the maximum pressure or potential impressed by the signal upon any insulators.

In an ac circuit, voltage, current, and resistance are not related so simply as they are in a dc circuit. This means that in order to handle ac, we must make some minor modifications in Ohm's Law. Unfortunately, our space for each installment of this course is somewhat limited, and so we must delay any discussion of the modification until next time when we will go on to examine more effects of ac. Now we must go on to see just what makes a circuit.

What Makes A Circuit? All the way through this installment, we've been taking the word "circuit" for granted in order to build some basic ideas. Now let's find out just what makes a circuit a circuit.

One of the standard textbooks used to introduce engineering students to radio defines an electric circuit as "the path taken by an electric current from its source through all of the components of the circuit and back to the source."

The only thing wrong with this definition is that it uses the idea of "circuit" to define "circuit." Let's modify it just a bit, and call a circuit "a continuous path through which an electric current may travel." That's not completely accurate

either, but by taking the two definitions together we can proceed.

For now, let's look only at dc circuits. We'll go into ac circuits in the next installment. We'll assume that a battery is our source of electric current during the rest of this discussion.

The simplest circuit, using our definition rather than the textbook version, would be merely a length of wire connected from one pole of the battery to the other. Current would flow, but not much else would happen.

In order to do anything useful, we must include "components" in our circuit, and that brings us to the textbook's definition.

The most common qualities affecting simple electric circuits are resistance, capacitance, and inductance. Of these, capacitance and inductance are effective only when current flow is changing, so we'll consider only components which produce resistance when they're included in our circuit. Such components are called resistors.

Each component in a circuit is known as a "circuit element." The connecting wire is not usually considered to be an element if the circuit contains anything else.

Circuits are divided into three major categories, known as "simple," "series," and "parallel" circuits. "Simple" circuits are those which contain only one circuit element, such as the one shown as A in Fig. 7.

"Series" circuits contain two or more elements connected end to end, so that the current will pass first through one element, then through the next, and so forth until the current has passed all the way around the circuit. A series circuit of two resistors is shown as B in Fig. 7. Elements of a series circuit are said to be connected "in series."

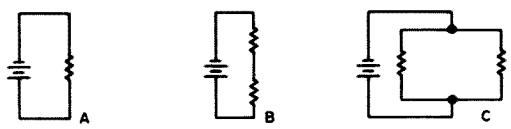

Fig. 7. These are, respectively, "simple" circuit (A), "series" circuit (B), and "parallel" circuit (C). Number of circuit elements (resistors here) and division of current flow are factors determining which type is which.

GATEWAY ELECTRONICS

6150 DELMAR BLVD., ST. LOUIS MO 63112
314-726-6116

SIGNAL GENERATOR – SG38/URM15 rf signal generator. 225–400 MHz. 115 volt ac power input.
Shipping wt. 75 lbs. $75.00

CERAMIC FILTER – 455 Kc. 3/8 x 3/8 x 1/16.
Shipping wt. ¼lb. ..... $ 1.00

AMPEX PLAYBACK TAPE DECK – reverses direction at end of tape. ¼ in. tape – speed 3¾ ips up to 14 in. reel.
Shipping wt. 60 lbs. $75.00

6.3 VOLT 10 AMP TRANSFORMER
Shipping wt. 2 lb. ..... $ 3.95

4 HENRY 450 mA CHOKE – 55 ohm.
Shipping wt. 8 lb. ..... $ 5.00

3.9 HENRY 500 mA CHOKE – 45 ohm.
Shipping wt. 9 lb. ..... $ 5.00

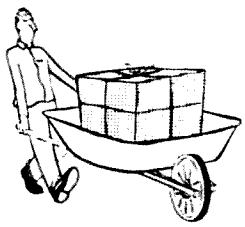
30 VOLT CENTER TAPPED TRANSFORMER – 115 volt primary – capable of 24 to 30 volts at 10 amps or 12 to 15 volts at 20 amps.
Shipping wt. 15 lb. $10.00

52 OHM COAX CABLE – Amphenol double shielded – similar to RG58A/U.
Shipping wt. 7 lb. per 100 ft ..... per ft $ .04

TELEPHONE OPERATORS HEADSET
Shipping wt. 2 lb. $14.50

4 MFD. @ 2000 VOLT DC CAPACITOR.
Shipping wt. 3 lb. ..... $ 3.95

COAXIAL RELAY – 24 volt dc with Type N connectors.
Shipping wt. 1½ lb. ..... $ 4.25



0–10 PIXIE TUBE – Burroughs #B9012 1 inch diameter.
Shipping wt. 1 lb. ..... $ 3.50

Minimum order $5.00. Sorry, no catalog at this time. Write for specific items. Watch for our ads in 73. Stop in and see us when you're in St. Louis.

BACK ISSUE GUNSMOKE !

30, count 'em 30, stupendous tremendous (more handbooks than magazines) fascinating enormous devastating incredibly enervating back issues of 73.....

ONLY $6.00
postpaid worldwide

Yes...yes...yes...here is a golden opportunity to blow your mind on 30 back issues of 73. You send us $6 in negotiable securities, cash or check and we will send you an unbelievable miscellany of thirty different (all different) back issues, all from the 1960-1966 era. These are all rare collectors items. Every one could likely be worth a fortune to you. Who knows, you might even find a rare January 1961 in this pile! We don't even know what is in these packages. To keep costs down we have had these magazines packed into sloppy bundles by the Chimps from Benson's Wild Animal Farm (nearby). Watch out for banana skins. –If you want specific issues of 73 they are available at the low low (high) price of $1 each. Unless we don't have them, in which case the price is higher. –How about sending a bundle to a DX friend? Back issues of 73 are worth their weight in unicorn dung in most countries. –Money received without a shipping address will be used for beer.

73 Magazine Peterborough NH 03458

"Parallel" circuits contain two or more elements, none of which are connected in series. Each element is connected directly to the power source, so that current which flows through one element does not flow through any of the others. A parallel circuit of two resistors is shown as C in Fig. 7. Elements of a parallel circuit are said to be connected "in parallel."

The major difference between "series" and "parallel" circuits is that in a series circuit, all the circuit current flows through each element in turn, while in a parallel circuit, that current which flows through one element returns directly to the source and does not flow through any other elements in the circuit.

From this difference, we can determine how resistors combine in both series and parallel connections to give total resistance. If two resistors are connected in series, all the circuit current must flow through each. In the first, a part of the energy will be converted to heat, leaving less for the second. In the second, the remaining energy will be converted to heat, so that none remains to return to the source.

Let's use the circuit of Fig. 7B, and assume that one of the resistors has a resistance of 5 ohms and the other is a 10-ohm unit. Let's assume also that we measure total circuit current and find it to be 2 amperes.

By the rule set forth in Ohm's Law, the voltage across the first resistor must be 2 x 5 or 10 volts (E=IR). Across the second, it's 2 x 10 or 20 volts. Total voltage of the battery, then, must be 10 + 20 or 30 volts.

Now we apply Ohm's Law again, using the 30-volt value we just calculated for battery voltage, and the 2-ampere measurement of circuit current. Resistance must be 30/2 or 15 ohms (R=E/I). In a series circuit of resistors, then, total resistance must be the sum of the individual resistances.

Let's try it again with the same two resistors connected in parallel (Fig. 7C) and using the same battery. We know now that the battery's voltage is 30. We can use Ohm's Law to calculate current through each resistor individually. Through the 5-ohm resistor, it's 30/5 or 6 amperes (I=E/R), and through the 10-ohm unit it's 30/10 or 3 amperes. Since none of the 6 amperes going through the 5-ohm resistor flows through the 10-ohm unit, the total circuit current must be the sum of 6 and 3 or 9 amperes.

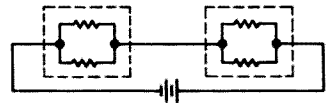


Fig. 8. Not all circuits are as simple as plain "series" or "parallel" connections. Subcircuits shown in dotted boxes are paralled connections, but subcircuits themselves are in series. Total circuit is called "series–parallel" but it could be reversed to "parallel–series" without changing components or connections simply by re-drawing dotted boxes. Most real circuits are like this, only more so.

With a 30-volt source and 9 amperes circuit current, we return to Ohm's Law and calculate total resistance as 30/9 or 3.333 ohms (R=E/I) – less than that of either resistor alone.

Effective values of resistors in parallel can be calculated in other ways, too, and some are much simpler. The way we've done it here, though, shows *why* resistance is lower, and is the basis for all the others. We'll meet the other ways next time around when we go into the manner in which other circuit elements combine in series and in parallel.

Incomplete circuits, which are complete except for their power source, can themselves be considered as a sort of circuit element in a larger circuit. Figure 8 shows a larger circuit with two such "subcircuits" in it, each outlined by dotted lines. Each subcircuit is a parallel circuit, but the two are connected in series. Such an arrangement is known as a "series-parallel" circuit.

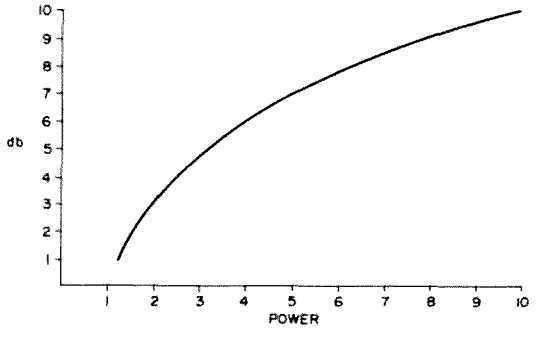
Most actual working circuits are even more complex than Fig. 8. The science of electrical engineering is largely devoted to determining how circuit elements are combined to form circuits, and using this knowledge to design new circuits.

Next Time

We've reached the end of our space for this installment, and still have not answered all the details of the FCC questions we chose for this round. This happened because the FCC questions mix

together some relatively simple ideas which are true in dc circuits, and some much more difficult concepts which apply only to ac circuits. This time, we've had to establish the foundation for ac circuits – but we haven't had space in which to build on it.

Next month, we'll go more deeply into ac circuits and complete the answers to this month's FCC questions, as well as to several more involving finer points of ac circuit theory. From there, we'll be in position to tackle more advanced problems.



If you want to study elsewhere while waiting, there are few texts available which follow the manner in which we're developing basic theory. If you can obtain a copy of "A Source Book in Physics" (by W.F. Magie, Harvard University Press, Cambridge, Mass., 1935, 10th printing 1969) it will give you the original reports of most of the leading scientists in electricity and radio up to 1900.

DB to Power

Here is a chart for changing decibels to power gain. Examples:

If an exciter runs 100 watts and it is fed into a 500 watt linear amplifier, the power gain would be five times and, by using the chart, the decibel gain would be 7 dB.

If 100 watts is fed to an antenna and the feedline has 3 dB loss, by using the chart, half of the power is delivered to the antenna.

Higher values of dB can be calculated by multiplying both co-ordinates by ten, by a hundred, etc.

Doug Pongrance WA3JBN ■

INTERESTED IN SSTV/FACSIMILE?

Investigate ALDEN surplus scanners today. The ALDEN 11 and 18 Series Flat Copy Scanners are the only high quality optical scanners manufactured for flat copy acceptance of graphics requiring wide scanning widths and endless lengths. Scanners have available options which include automatic background control and FM modulators. Output is 1800 or 2400 Hz AM (selectable) at 0 dB, 600 ohms.

With facsimile, you receive hard copy rather than a transient display. Imagine. . .instant QSL'ing, transmission of circuit diagrams, pictures of your shack, etc. Price ranges from $2,700 to $6,500 depending on model and age. (Original selling prices were $6,000 and $10,000.)

To complete your loop, ask about ALDEN surplus 11" and 18" facsimile recorders as well. Call or write:

Technical Aid Group

Please refer any questions of a technical nature to one of the following members of 73's Technical Aid Group. These are dedicated amateurs who really want to be of help and do so without compensation. Be sure to state your problem clearly and enclose a S.A.S.E. for a reply.

John Allen K1FWF, high school student, 51 Pine Plain Road, Wellesley, MA 02181. HF and vhf antennas, vhf transmitters and converters, AM, SSB, product data, and surplus.

Stix Borok WB2PFY, high school student, 209-25 18 Avenue, Bayside, NY 11360. Novice help.

Joseph W. Botwinick K2EJI, 131-60 231 Street, Laurelton, NY 1141. Technical information required for Novice, General and other licenses.

J. Bradley K6HPR/4, BSEE, 3011 Fairmont Street, Falls Church, VA 22042 General.

Michael Burns Jr. K9KOI, 700 East Virginia Avenue, Peoria, IL 61603. AM, SSB, receivers, transmitters, digital techniques, novice help, general.

Glen H. Chapin W6GBL, 3701 Trieste Drive, Carlsbad, CA 92008. HF and vhf antennas, novice transmitters and receivers, vhf converters, semiconductors, receivers AM, SSB, general, surplus.

Ted Cohen W4UMF, BS, MS, PhD. 6631 Wakefield Drive, Apt. 708, Alexandria, VA 22307. Amateur TV, both conventional and slow scan.

Bruce Creighton WA5JVL, 8704 Belfast Street, New Orleans LA 70118. Novice help and general questions.

George T. Daughters WB6AIG, BS, MS, 1560 Klamath Drive, Sunnyvale, CA 94807. Semiconductors, vhf converters, test equipment, general.

Gary De Palma WA2GCV/9, P.O. Box 1205, Evanston, IL 60204. Help with AM, Novice transmitters and receivers, vhf converters, semiconductors, test equipment, digital techniques and all general ham questions.

Steve Diamond WB6UOV, college student, P.O. Box 1684, Oakland, CA 94604. Repeaters and problems regarding legality of control methods. Also TV, novice transmitters and receivers, vhf antennas and converters, receivers, semiconductors, and product data.

Frank M. Dick WA9JWL, 921 Isabelle Dr., Anderson, IN 46013. Will answer queries on RTTY, hf antennas, vhf antennas, vhf converters, semiconductors, mobile, general, and microwave.

Willy P. Everaert ON4WM, Park ten Hove, 97, 9230 Melle, Belgium. SSTV (test tapes available), weather satellite picture decoding systems, and digital circuits. Appreciates IRC's for return postage on inquiries.

David D. Felt WB6ALF, 79 East Highland Ave., Sierra Madre, CA 91024. Semiconductors, IC's, television, test equipment, product data.

Louis E. Frenzel, Jr., BAS, 11287 Columbia Pike, Silver Spring, MD 20901. Electronic keyers, digital electronics, IC's commercial equipment and modifications, novice problems, filters and selectivity, audio.

Paul Gorrell, high school student, P.O. Box 228, Mashpee, MA 02649. Novice transmitters and receivers, hf equipments, CB to ham gear conversion. Marine to ham gear conversion, Civil Air Patrol Communications, all aspects.

Orris Grefsheim WA6UYD, 1427 West Park, Lodi, CA 95240. TV, hf antennas, SSB, vhf antennas and converters receivers, semiconductors, and general questions.

Bob Groh WA2CKY, BSEE, 123 Anthony Street, Rochester, NY 14619. Specializes in vhf/uhf solid-state power amplifiers, but will be glad to make comments on any subject.

D. E. Hausman VE3BUE, 54 Walter Street, Kitchener, Ontario, Canada. Would like primarily to help Canadians get their licenses. Would be able to help with Novice transmitters and receivers.

Charles Hill WA7LQO, 237 Bridge St., Baker, OR 97814. Slow scan TV.

Sgt. Michael Hoff WA8TLX, Box 571, 6937th Comm. Gp., APO NY 09665. Help with all types of RTTY both commercial and military. Also data techniques. Covers conversion of military RTTY equipment.

Iota Tau Kappa Radio Fraternity W7YG, Multnomah College, 1022 SW Salmon St., Portland, OR 97205. This group of radio amateurs will answer any technical questions in the field of electronics.

Douglas Jensen W5OG/K4DAD, BA, BS, 2505 Broadway, #1704, Houston, TX 77012. Digital techniques, digital and linear IC's and their applications.

Jim Jindrick WA9QYC, 801 Florence Avenue, Racine, WI 53402. Novice transmitters and receivers, general.

Ira Kavaler WA2ZIR, BSEE, 671 East 78 Street, Brooklyn, NY 11236. SSB transmitting, color TV, computer programming and systems, digital radio and remote control, rf transmission lines, dipole design, audio amplifiers, linear and class C rf amplifiers.

Ronald King K8OEY, Box 227, APO NY09240. AM, SSB, novice transmitters and receivers, hf receivers, RTTY, TV, test equipment, general.

Ken Knecht K8VNT/2, Box 39, Clintondale, NY 12515. Novice help and general questions.

G. H. Krauss WA2GFP, BSEE, MSEE, 70-15 175 Street, Flushing, NY 11365. Will answer any questions, dc to microwave, state-of-the-art in all areas of communications circuit design, analysis and use. Offers help in TV, AM, SSB, novice transmitters and receivers, vhf antennas and converters, receivers, semiconductors, test equipment, digital techniques and product data.

Tom Laffin W1FJE, Hillsboro, NH 03244. Authoritative information on ham radio's fundamental beginning works. Documentary info on

the historical scientific period 1887 to 1954. References include but not limited to The Annual Report of the Smithsonian Institution, electrical engineering texts, National Electrical Codes, the hard-to-find data.

Bert Littlehale WA1FXS, 47 Cranston Drive, Groton, CT 06340. Novice transceivers, test equipment and homebrew projects gone wrong.

J. J. Marold WB2TZK, 279 Farmers Ave., Lindenhurst, NY 11757. General.

Wayne Malone W4SRR, BSEE, 8624 Sylvan Drive, Melbourne, FL 32901. General.

Charles Marvin W8WEM, 3112 Latimer Road, RFD 1, Rock Creek, OH 44084. Will help with any general amateur problems.

Carl Miller WA6ZHT, 621 St. Francis Drive, Petaluma, CA 94952. Double sideband.

Fred Moore W3WZU, broadcast engineer, 4357 Buckfield Terrace, Trevose, PA 19047. Novice transmitters and receivers, hf and vhf antennas, vhf converters, receivers AM, SSB, semiconductors, mobile test equipment, general, product data, pulse techniques, radio astronomy, bio-medical electronics.

Eduardo Noguera M. HK1NL, EE. RE, P.O. Box Aereo 774, Barranquilla, Columbia, South America, antennas, transmission lines, past experience in tropical radio communications and maintenance, hf antennas, AM, transmitters and receivers, vhf antennas, test equipment and general amateur problems. Can answer questions in Spanish or English.

Tom O'Hara W6ORG, 10253 East Nadine Temple City, CA 91780. ATV, vhf converters, semiconductors, general questions.

John Perhay WAØDGW/WAØRVE, RR #4 Owatonna, MN 55060. AM, SSB, novice transmitters and receivers, hf receivers, vhf converters, semiconductors, mobile, product data, general. Has access to full specifications on almost all standard components presently catalogued by American manufacturers.

Arthur J. Prutzman K3DTL, 31 Maplewood, Dallas, PA 18612. All phases of ham radio. Can assist with procurement of parts, diagrams, etc.

Howard Pyle W7OE, 3434 7th Avenue, S.E., Mercer Island, WA 98040. Novice help.

Robert Scott, 3147 East Road, Grand Junction, CO 81501. Basic electronics, measurements.

Pfc Grady Sexton Jr. RA11461755, WA1GTT/DL4, Hedmstedt Spt. Detachment, APO NY 09742. Help with current military gear, information from government Technical Manuals.

Walter Simciak W4HXP, BSEE, 1307 Baltimore Drive, Orlando, FL 32810. AM, SSB, Novice transmitters and receivers, vhf converters, receivers, semiconductors, mobile, test-equipment, general.

Richard Tashner WB2TCC, high school student, 163-34 21 Road, Whitestone, NY 11357. General.

Roger Taylor K9ALD, BSEE, 2811 West Williams, Champaign, IL 61820. Antennas, transistors, general.

Jon Teich WB2JAE, 22 Olden Road, Ediron, NJ 08817. General assistance and problems with rigs.

James Venable K4YZE, MS, LLB, LLM, 119 Yancey Drive, Marietta, GA AM, SSB, novice gear, vhf, semiconductors, and test equipment.

Hugh Wells W6WTU, BA, MA, 1411 18th Street, Manhattan Beach, CA 90266. AM-FM receivers, mobile test equipment, surplus, amateur repeaters, general.

William G. Welsh W6DDB, 2814 Empire Ave., Burbank, CA 91504. Club licensing classes and Novice problems.

Michael Winter DJ4GA/W8, MSEE, 718 Plum Street, Miamisburg, OH 45342. HF antennas, AM, SSB, novice gear, semiconductors.

Joseph Zaroff WN3NEQ, RR 1, Washington Crossing, PA 18977. Novice gear, antennas, vacuum tube circuits, construction of homebrew projects.

Protection for Grid Dipper Coils

All who have used one will agree that a grid dip meter is indispensable to the active homebrewer. It will insure that your tripler will triple rather than double. It will double as a wavemeter or signal generator and in general is one of the most useful test instruments for the builder.

As a result of the multiple uses to which they are put, the average grid dipper soon becomes rather dog-eared. The coils especially are subjected to abuse above and beyond the call of duty. Some coils have the protection of an outside coil form which keeps the coil proper in good condition; however, more often the coil is wound on the outside of the form and covered with a thin layer of coil dope or shrinkable tubing. Either of these soon loses its effectiveness and mechanical problems set in.

Having experienced the above problem with my dipper, I have tried several cures. The one to be described answers every requirement. I bought a bottle of "Clear-Cast" casting plastic from a local handicraft supply store along with the required small bottle of catalyst. Mix a small portion (3 to 4 ounces) according to the directions on the bottle. Remove any loose coil dope or tubing and dip the coil into the plastic up to the terminals. Remove the coil and let it drip a few moments, then suspend it, terminals up until dry. Repeat with each coil. A second coat may be added after the first is dry, but the mixture is thick enough that it really isn't necessary.

Tests before and after processing indicate no change in coil characteristics. With this tough coating the life of your coil should be extended to the life of the terminals.

William P. Turner, WAØABI

Turner M+2

A microphone with a built-in compressor/amplifier that can give you 20 dB more talk power on sideband.

With sideband transceivers getting more plentiful on the used market and the very reasonable price on the Heath single banders and the WRL Duo Bander, many of us have gone mobile and more are giving it serious thought.

The big disadvantage is the inefficiency of the antenna system. A 100 ampere alternator with the Heath Kompact KW linear will help overcome the antenna losses. But so will fully modulating the transceiver by adding a speech compressor.

The Turner M+2 microphone has a silicon transistor compressor built in, complete with a 7-volt battery that will last under normal conditions up to twelve months. There is an output control on the back of the mike.

Perhaps you will be interested in the results I've had using the M+2 microphone with my Heath HW-12A and Kompact KW combination. I first used the Turner 350-C, the one that Heath sells for mobile use, and got signal strength reports from several local stations. Then I switched off the linear and changed to the M+2 and found that the signal reports were exactly the same as before!

Using both the M+2 and the Kompact KW with the HW-12 results in a tremendous mobile signal.

You should use a scope to properly set the gain controls on the mike and on your rig since the output of the M+2 is very strong; as great as -30 dB to 1 megohm load. With this much talk power you can very easily overmodulate or flat-top. I run the mike volume control at 9 and the mike gain on the rig at about 2 o'clock.

The price of $23.70 is probably the least you will ever pay for 20 dB gain. Good luck with your BIG mobile signal.

. . . Ralph Compton WA5JVQ ■

YOUTH FORUM REVISITED

With all the turmoil among our young people today it's almost dangerous to entitle a column youth forum. Relax; I'm not going to urge anybody to seize the administration building at the ARRL or any such nonsense. The purpose of this column is to promote interest in ham radio in our teenagers.

The problem is not to get them to get their Novice licenses; it's so easy that anybody can do it in a month or less. The problem is to get them to go for their General or Advanced. Many Novices never go on to get their higher class license. The most common excuse is that they "lost interest." I can see where they would. Let's face it – the Novice band is crowded, there's very little DX, and no voice operation. You can work just about as much DX on Citizens' Band as on the Novice band – and you can use voice.

While talking to one of the local Novices, I noticed that his interest was beginning to drop. I invited him over to the shack after supper to try and boost his morale. I had the transceiver running when he came in and invited him to tune around 20 meters to get the feel of it. The results were amazing. He went wild when he heard a few DX stations. I worked a couple to impress him a little more. For the clincher, I went down to 75 and let him listen to some of the European gang coming in. This left him numb. His best DX on 80 had been a WN9. The last time I saw him he was hitting the books hard and I believe he's going to make it now that he has an idea of what ham radio is really like.

Many more people would be willing to work for a ham license if they had a good idea of what ham radio is like. Many of the magazines which are aimed at electronics in general (PE, EI) look at ham radio from a Novice point of view. The ham magazines are incomprehensible to a non-ham.

So if you know someone who has expressed an interest in ham radio, invite him to the shack and show him why it's worth the effort to learn code and theory. Give him a true picture of ham radio; don't just hand him an old copy of *How to Become a Radio Amateur*, which shows him how to build a regenerative receiver for the ham bands (and other white elephant projects).

Many Novices come to me asking what equipment they should buy. My checking account is still hurting from some of my financial misadventures as a Novice, so I guess that puts me in the "veteran" class. The lessons I learned might be of value to others, too. If interest warrants, I will list a few tips in a future issue on spending money for ham equipment.

. . .Andy Bourassa WA1LJJ ■

MOBILE CW RECEIVER

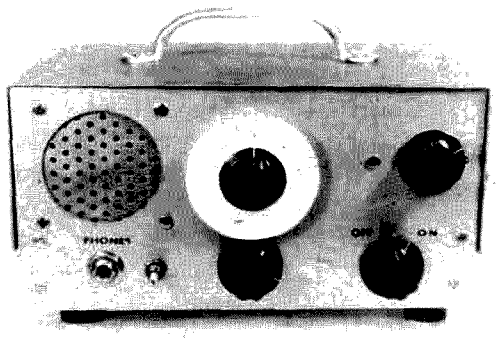
Just before vacation time many amateurs begin to get the urge to build portable equipment. Often last-minute construction jobs never get finished in time for vacation, especially if new circuits using FETs are tried. This is a story of a similar rush project where reliable tube circuits were used to finish the receiver the day before vacation. The receiver worked so well, the information is presented here for those of you who want to plan ahead for next year's vacation trip.

This 80–40 meter receiver uses four 6U8 tubes so that only one tube need be taken along on field trips for the spare. Each pair of tubes has the filaments wired in parallel so that the entire filament supply can be operated from the 12V car battery. The plate supply only draws about 15 mA, and the receiver can be run from

Ed Marriner W6BLZ
528 Colima Street
La Jolla CA 92037

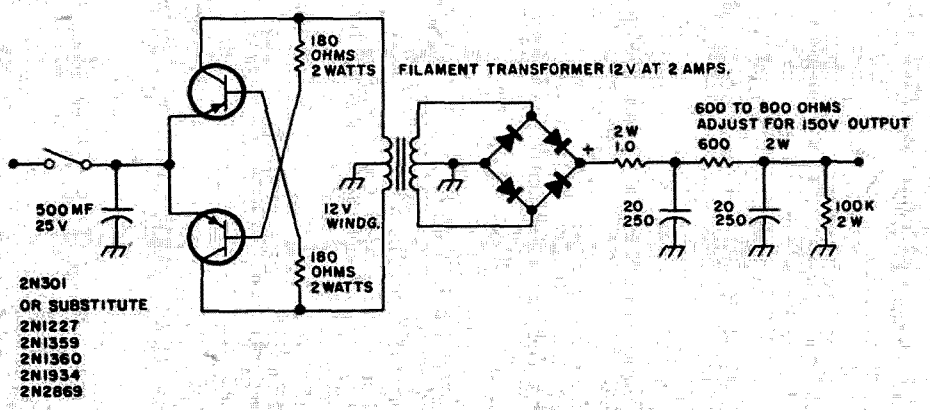
three 45V dry batteries if a mobile supply is too much work to construct.

Designed especially for CW reception, a product detector was used. A 2.5 kHz bandpass i-f filter was made from two surplus low-frequency crystals. Plug-in coils were used to make wiring and band changing easy. Only one coil has to be changed when going to the other band. The mixer and rf coils are tuned to both 80 and 40 meters by using a large broadcast-type tuning condenser which covers both of the bands in the tuning range.



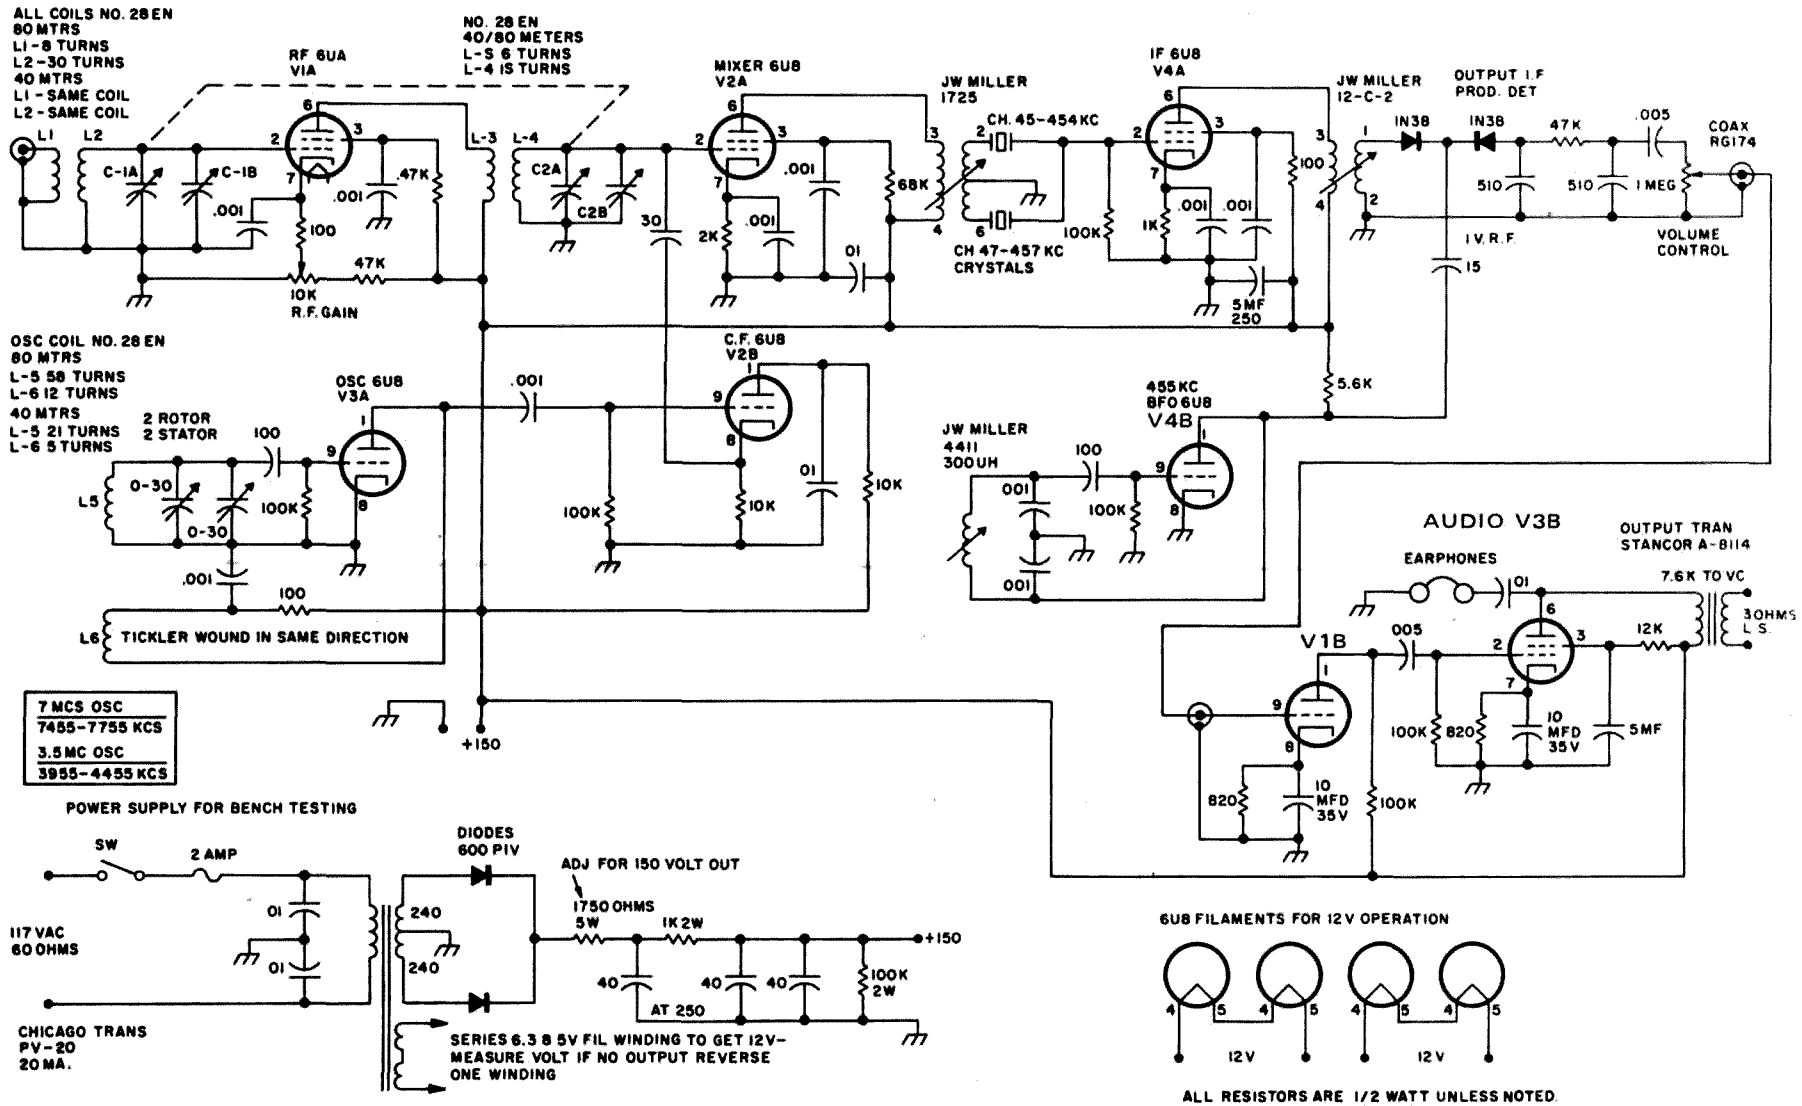
The low frequency i-f gives good selectivity, but images from strong commercial stations could pop in the ham band if they are near in location.

Theory



Starting off with the rf stage, the antenna signal is coupled to the grid through L1 and L2 and then fed to the mixer through L3 and L4. These coils are tuned by a ganged 365 pF tuning condenser so that one coil covers both the 80 and 40 meter bands. The ratio of coil to condenser is adjusted to have enough capacity to prevent unstable oscillations which might reflect back on the oscillator tuning.

The variable oscillator which tunes 3955–4455 kHz for the 80 meter band or 7455–7755 kHz for the 40 meter band is injected to the mixer through a cathode follower. This follower is necessary to prevent signals in the mixer from getting back into the variable oscillator and causing frequency shift. The follower is necessary. The oscillator oscillates with a strong signal to give enough injection to the mixer. Insufficient signal to the mixer also causes mixer oscillations.



The output of the mixer is fed through a crystal filter which has low loss, and only one i-f stage was necessary since there was

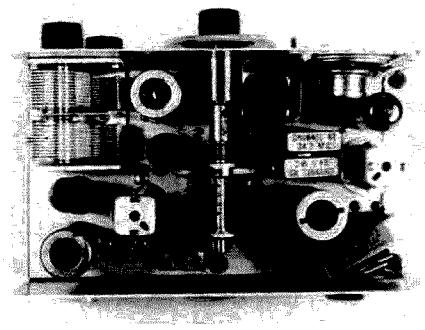
Front view of receivers showing the epicyclic ball-bearing drive head for the dial fitted with a home made dial plate. The mechanism is 10 to 1 and can be obtained from British Radio, 142 Wisconsin Ave. NW Wash. D.C. Upper right are the ganged rf and antenna coil tuning condensers. Center lower knob is the rf gain control.

Mobile power supply for CW receiver.

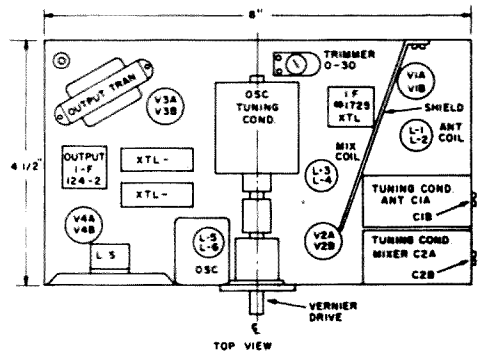
Schematic diagram of mobile CW receiver. Note: power supply should be kept away from receiver to keep field away from modulating the audio output transformer.

enough gain, and selectivity was obtained in the low-frequency channel crystals. This signal output from the i-f was fed into a product detector and then to the audio stages.

Circuit Discussion



Power to the receiver should not exceed 150V to comply with requirements to the triode section of the 6U8s if long life is expected. As it turns out, there is plenty of gain using 150V, and the receiver works very satisfactorily with only 150V or less. Volume is more than enough for earphone reception, but the 6U8 will drive a speaker, although the tubes were not designed as audio output speaker drivers. The output transformer is a little higher impedance than necessary, but it cuts down on the tube current and is better when used as the auido choke for earphone reception. The tiny transistor speaker could be replaced with a larger speaker – there is enough drive.



The diodes used in the product detector should be of the germanium type to obtain leakage; do not try to use silicon types if the 1N67s or 1N58s are not available. Low-leakage diodes cause the signal to block.

Crystal filters were made from two surplus crystals to give a selectivity of 3 kHz. If too narrow a bandpass is used the i-f stage will oscillate. A J. W. Miller No. 1725 i-f transformer specially designed for coupling into the crystals was used. It tunes the 455 kHz channel 45 and channel 47 ranges. Experimenting is in order if you have the time to try various bandwidth crystals and adjustments of the i-f transformers, but the crystals indicated will give all the selectivity necessary. The i-f signal needs about 1V from the bfo to mix properly and be passed on to the 47 kΩ, and 500 pF capacitors used as the rf filter.

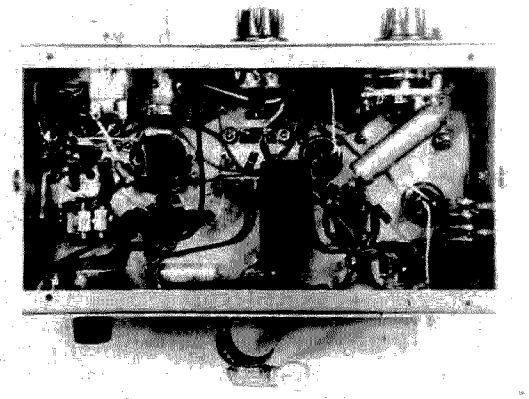
Construction and Tuning

The receiver is built on a California Chassis type A-119 which is 4¼ x 8 x 1½ in. The dial drive is a British Radio vernier type No. 892 with a 5-to-1 ratio. More ratio could be used because the receiver does tune sharply. Parts placement can be changed around, but it is suggested the tube arrangements be used as shown. It was found necessary to remove the variable oscillator from the same envelope because the mixer tube pulled the oscillator. Experience is a great teacher, and some of the troubles can be prevented by following instructions.

Top view of receiver with the crystal filter and output i-f transformer to the left of the tuning condenser. Note the oscillator coil is shielded.

Once the receiver is wired it can be aligned by listening to the 40 meter signals, although initial adjustments can be made with a signal generator and a modulated tone when peaking the i-f's. During the tuning, be careful you don't screw the slugs off the threads. Since only 150V was used it was not necessary to use the customary 1000Ω and .005 μF bypass condensers around the various supply leads to prevent interaction between circuits. Placing a single 40 μF condenser on the chassis gave

enough filtering to stop coupling except for the audio supply where a 5 μF and 10Ω resistor helped the filtering.



Once the i-f stages are aligned, peak up the rf and mixer condenser C1B and C2B. It is best to set the mixer tuning at a maximum peak, then adjust the trimmer for most signals, and then go back and peak the antenna trimmer. If there is not enough capacity, tuning of the condenser will cause oscillations. The trimmers were set almost full mesh with the number of turns given in the coil table. A separate antenna trimmer could be mounted on the panel if antennas are often changed because the trimmer has to be retuned when another antenna is used. Best performance can be obtained if a good antenna is used, such as an 80 meter or 40 meter resonant antenna, and although the receiver will work on ten feet of wire, the input is designed for low-impedance coupling.

While probably not necessary, it is a good idea to use the EBY tube shields over the tubes to prevent coupling between parts. An aluminum shield between the mixer and antenna coils is another good suggestion. The more shielding is insurance against possible oscillations between circuits.

The circuits in this receiver all tend to be high Q which gives the most signal output; however, it is best to be safe, and back off if necessary on some adjustments to give reasonable output with no oscillations. Since C1A and C2A tune the range 80 to 40 meters, there is no need to change plug-in coils when going from one band to the other. The condenser tracks satisfactorily. The oscillator coil does have to be changed.

The most difficult problem with aligning the receiver is to calibrate the variable tuning condenser. It is easier to pull out plates to obtain the proper bandspread and increase the 0.30 pF trimmer to compensate for the loss in capacity. The output of the oscillator can be picked up on the receiver in the shack if you have one; if not, try using the grid dip oscillator. Make sure the signal is on the high side of the amateur band because it is easy to slip the trimmer over to the low side. Once you set the 7.0 MHz position on zero, the 3.5 MHz position can be brought to zero by spreading the bottom turns of the 3.5 MHz oscillator coil until it is positioned on zero also.

During the tuning process the bfo was assumed to be peaked for a beat note by screwing in and out on the slug coil for proper tone. Try to use two silver mica capacitors across the bfo coil. Heat tends to make the small ceramic types drift.

Bottom view of receiver. Bfo slug coil is between earphone jack and rf gain control.

The details of the adjusting process can become boring to those more familiar with construction but this description should be satisfactory for those building the receiver. It will become apparent as you play with the adjustments what you can and cannot do, or where the limits of adjustment lie.

This receiver performs very well with plenty of volume for all normal portable or mobile work where CW is the primary interest. It will mount on the dash of most autos by cementing magnets to the bottom of the chassis unless you have a padded dashboard. No attempt was made to put it on 20 meters, but it would work except that the images would be more of a problem as you need more selectivity using the 455 kHz i-f's when going to the higher frequencies.

QSLing

HAM RADIO'S OWN CON GAME

In every human activity, sadly, there is to be found a racket of some sort and the QSL *situ* in our hobby is no exception. Compared to the magnitude of swindles outside of amateur radio, the card business falls under the classification of petty exploitation.

Those who don't or won't QSL fall into several categories. Firstly, there's the well intentioned bloke who is always *going* to get down to writing out his QSLs – but years have gone past and he's not faced it yet and you could safely take the odds at ten to one that he never will. There are many like this among us whose sins are those of omission, rather than commission. Lack of discipline is probably the commonest of human failings. While it is possible to tolerate these characters and philosophically accept the couple of dollars lost in IRCs, AMs, etc., in a futile attempt at verification, they nevertheless are living a daily lie, in that they blithely go on ending each QSO with "QSL sure"; adding nothing worthwhile to the standard of ethics or goodwill of our hobby.

Then there is that broad group who *don't intend* to QSL. These are the cheaters, the deceivers, and the small-time opportunists. They bring to ham radio the doubtful tone of the rat race outside. To these fellows, ethics and fair play are virtues for the squares. Among them is the type who sends his address with each QSO and promises to reply "as soon as I get yours." The verification never comes. The intention only is to take.

More than one possessor of a rare call is playing the averages. A DXpeditioner in Africa, who subsequently sent no cards, was heard telling a mate in a ragchew, "I've worked one hundred VKs; that should cover me in that direction."

In any company there's always a shylock or an exploiter who wants more than his pound of flesh. One who is determined to *sell* his call at the best possible price and show a little profit on his QSL printing costs at the same time. His request is anything up to five IRCs and SASE with your card – or make a contribution pse? For what? A check shows he has access to

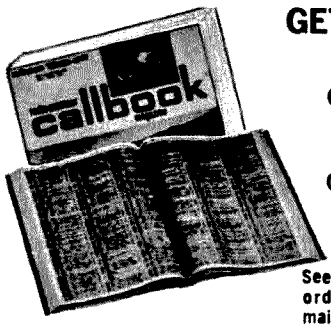
a bureau, so a card is sent via this facility, followed by another, and maybe at a later date, yet another, but ND.

Then we have the manager/ham setup, a combination that's brought more than one piece of connivance into existence. True, the QSL manager has a real place in the modern scene. Most do their job ethically and well and provide a prompt service. Their assistance to hams in isolated areas cannot be overemphasized. But many managers are superfluous and the deceivers in this field are growing. I lay the blame directly on many U.S. hams. Anyone with a rarer than average call is swamped with offers to write the QSL service. The true reason being that the helper helps himself out of the bog of nonentity that threatens to flood those in countries that have a large ham population. It's a two-way status stretch. Both attain greater importance and identity and if the business is handled properly, there's sure to be a little capital profit.

My call sign is not one to be put up in large letters or attract a queue of callers, but offers of QSL services have come from the States (possibly quite ethical) and one commercially minded character wrote from the U.S. offering to relieve me of the workload at a pretty stiff fee per thousand cards sent. A middle man, out to show a profit both ways and gain the status of a manager to boot.

In defense of making panting aspirants pay to obtain a rare QSL, one DXer put it to me this way: "I really only come on the air to give the world a new country. Every time I press the key the queue quickly lengthens to infinity. I make several thousand QSOs a year. The QSL costs are beyond me. Nor can I afford the time."

In such a case the adjunct of a manager is quite in order. In fact it's a must, but the charitable bit about helping the boys to a new one is in reality most likely a rationalized half-truth in order to seek privilege. He's providing a new country, yes – but gaining considerable status in the process. The cost of the QSLs are still largely his responsibility, or a matter of arrangement with his manager; and the body of hams who make a QSO should not have to meet the cost of printing two QSLs and postage both ways. G2MI, who through his bureau has probably handled more QSLs than any other ham alive, recently made a comment to the effect that it behooves every ham to handle his own QSL affairs if he possibly can. I heartily concur.



In days past, when I sent IECs, SASEs and "contributions" etc. to those who requested them, my QSL return was between 75 and 80%. Nothing outstanding in this considering I was buying what I wanted. However, after a personal moment of truth wherein I rearranged my values a little and decided the dollars posted could be better used elsewhere, I sent my QSLs via the bureau (where this was possible) to a manager or direct S.M., but with *no* IRCs. Result: a 15% return. Draw your own conclusions. As in other levels of our society, the humble pay and the exalted claim privilege.

I was recently instructed by a manager to send SASE with my card for direct reply only. "Have no bureau and can't afford the time to cope with stamps and envelopes," he said. Special circumstances do occur, but in general the manager who has not the machinery or the time to provide an equitable service should not set himself up as a QSL caretaker. Getting stamps for SASEs is not possible for many hams.

Of course the line of distinction as to what's ethical and what's snide is often difficult to draw. The fast, modern, country-hopping ham DXpeditioner is continually calling for contributions to defray expenses and promote the venture further. Fair enough, and I've been happy to oblige, but the case customers naturally say, 'I'll put in a buck or two, if I get a QSL.' The end result of this in some cases is a little bribery or corruption.

The inequities outlined above are but a few of those indulged in. We all know of the much-boasted claim of those who simply consign SWL reports to the waste-paper basket. To write a reply and encourage a beginner is beyond the range of their compassion. Then there's that group who will only send a QSL to those from whom they want a verification. No thought is ever given to the many who may want a QSL

"If you have a dime, I'll see if the phones are working!"

from them. The day of the counterfeiter is not past either. They've appeared in the past and will do so again. Why spend hours and hours chasing a real rarie, when you can print your own? But these sharpies come quickly to grief. Printing and getting away with a phony QSL is harder it seems than passing a bad $10 note.

This brings one to the point of how to deal with the QSL deviate or purify the scene in general. Unfortunately, no encouraging prognosis is possible. So long as so few are so fanatically chased by so many, the prospect of elevating our QSLing standards is not bright. The blackmarketeer will continue to exist so long as he has the clientiele of Mr. Average Ham. Even the most honorable rare-country ham, on finding his QSL mail laced with dollars, is tempted to operate out of cupidity rather than for the art of DX itself. Is it the QSO or the almighty dollar that's sought? Likewise, the "seekers" don't really want the QSO – only the QSL. From here it seems only a simple step to dispense with the ten-second QSO and just send the card as a swap for the dollar.

The best improvement that can be hoped for, it seems, is an eventual "buyer resistance" to the card sharpie. DX-wise, the world is rapidly shrinking and an increase of hams in some of the emerging countries will take the novelty out of many exotic calls. I am optimistic too, that much of the activity created from pursuing new awards will become more selective. A glutted market results in discerning applicants, and no one will deny that the award field is pretty well saturated.

A gentleman's agreement is in truth an unwritten law and by this virtue alone it should be more binding than one imposed by constitution. It appears than many simply don't understand the real meaning of such an agreement. The ethics of QSLing are such that it is tawdry piece of business to *sell* one's call in a service that's called *amateur*. If the spirit of our hobby is to be truly observed and preserved, it is obligatory on each and every ham who says he QSLs to do so at par – or as near to this as possible.

(continued from page 10)

transmitters, scanning receivers, handie-talkies, and such would proliferate.

The FCC would not only gain by getting back their 11 meter band for its original purpose, but would get several million dollars in fees for the new license and would get rid of the fantastic headache of even trying to monitor CB. 220 would, like other amateur bands, be self-monitoring. The FCC has a responsibility for the number of engineers and technicians in the country, since their regulations so profoundly affect this situation; this new license should greatly improve this situation.

The FCC would gain . . .the amateurs would gain . . .the country would gain . . .CB'ers would gain . . .and the manufacturers would gain. Everyone gains, and the best part that no one loses anything! Can you ask for a better deal than that?

It is estimated that some 25% of those active on CB now are unlicensed and that when the new prices go into effect that this could go up to 75%. The type of operations that we would have on 220 would eliminate the things that make illegal operation possible. Everyone would have a call . . .would be listed in the Callbook . . .would have QSL cards, etc. The whole thing would become legitimate. The ease of direction finding and the lack of skip contacts would soon stop all illegal operations.

DX'ing on FM

Ken was so enraptured with the beauties of southern New Hampshire that I thought it might be fun to blow his mind by taking him on a tour through the Presidential Range of the White Mountains, some 120 miles north of Peterborough. Ken packed five of his seven children into his car, but two kept popping out so Lin and I took them along in our car, along with Sage, now just five months old.

We headed up north, taking the back winding roads. We used mobile units on 146.94 FM to keep in touch. The system worked pretty well except for repeaters breaking our squelch a good deal of the time. Everyone enjoyed the Morse Museum in Warren, N.H., and the Lost River Caves. The high point of the trip probably was the tramway trip to the top of Cannon Mountain, with an FM Handie-Talkie in hand. From the top of Cannon we were able to break the repeaters all over New England. The best contact we had was with a mobile in Ontario, a total of 200 miles away, through W1KOO on Mt. Mansfield in Vermont. We had no trouble breaking W1KOO, a little over 50 miles away, and working stations one after another through it. We also made some contacts down in Massachusetts through W1ALE in Concord, N.H., about 70 miles away.

That evening, while visiting my folks just outside of Littleton, N.H. I tried the Handie-Talkie and found that I could break W1KOO from there too. Again, this was a good 50-mile hop. So I sat there in the livingroom of the farmhouse, talking with fellows over in Vermont, New York and up in Montreal. I also managed to work Ken, just three miles away in a motel, and guide him to the farm. The Handie-Talkie transmitted on 146.34 and received on 146.94, and since Ken had no crystals to receive on 34, he had to talk with me through W1KOO, a one-hundred mile path, even when he was parked in front of the farm.

The next day we headed off to Mount Washington. From there we made contacts through W1KOO and W1ALE again, plus W1ABI, and perhaps others. The local FM and TV transmitters raised the noise level and made it a lot more difficult to work out. Ken did a bad job on his hand on the way up the mountain, burning it when his radiator boiled over, so we didn't stay on top nearly as long as we might otherwise have. It takes third degree burns to keep Ken off the air for any length of time.

It is difficult to really describe the excitement of making contacts from the farm, but I've been visiting it for most of my summers for well over forty years and it is home to me. We've never had electricity there, nor water other than from a spring up on the hill which runs into the cellar and can then be pumped into the kitchen with a hand pump. It is about as remote as you can get these days. Yet, remote as it is, I could sit there and talk for hundreds of miles with my little Handie-Talkie.

One Dollar a Copy?

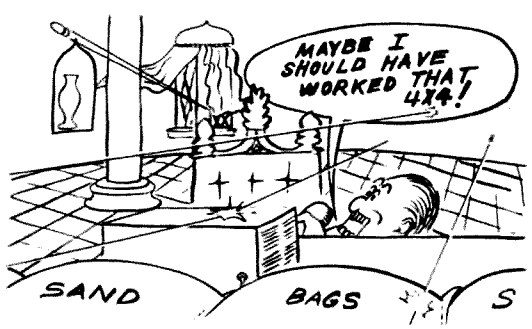
We increased the cover price of 73 earlier this year, expecting the worst. There was little choice . . .either we made the magazine smaller, publishing fewer articles, or else we had to raise the price. We took the gamble. We figured that since 73 published more articles than the rest of the magazines, the extra quarter was not really significant. We figured, but we didn't know.

The results are now coming in and I must truthfully tell you that the sales of 73 did change. . .they changed a lot more than I guessed they would. The sale of 73 went up. . .way up! 73 now has, our distributors tell us, the largest single copy sale of any amateur radio magazine in the world, and by a comfortable margin.

Subscriptions have been peaking up too, probably as a result of new readers paying a dollar for a copy and then noticing that there is a substantial saving when one buys a three year subscription for $12 instead of $36 on the counter. With more postage increases on the way, our subscription rates will have to go up appro-

priately. Sorry about that. Right now the lifetime subscription is by far our best bet, and you can buy it on the installment plan! $10 down. This too, alas, will be going up shortly. . .probably to $75.

Other Magazines



Four more magazines are in the works up here at 73 Hq. Radio Today is still in its early stages with just two issues published so far and acceptance at a high level from both readers and advertisers. Once it is strong enough to keep itself going we will begin work on introducing the next one. One is in the two-way field. . .one is a house organ for one of the big conglomerates. . .one is an entertainment magazine. . .one is about bringing up children. . .and a possible fifth is being researched for the gourmet field. There is a lot of money to be made in publishing today (in everything but the ham field), so this is a good time to take advantage of the plant we have built up, a plant that has the equipment and personnel to produce a number of magazines ready for printing, complete printing equipment for promotion and small books, etc. All this is only being partly used for 73 and Radio Today, so we can turn out a few more magazines.

Opportunities at 73

Our magazine is growing, as you may have noticed. This means that we have to add to our staff every now and then. Possibly you have thought about working in your major hobby. . . ham radio. . .if so, you might enjoy working for 73. We occasionally have openings that could best be filled by interested amateurs. The openings may be in bookkeeping, circulation, promotion, advertising, proofreading, typing, drafting, printing, or layout or even a combination of several of these fields. Most of all we need people who are interested in helping amateur radio to progress rather than just wage earners. Drop us a line and a resume if you like 73 and are interested in living in the most beautiful spot in the country.

Please would it be possible for you to insert my name and address in 73 as I would like to get one or two pen pals in other parts of the world who are as intensely interested in all aspects of ham radio, TV, and electronics as I am. I am nearly 16 years of age, in my third year at college (fifth form), and have all the normal interests that a healthy male of my age should have, especially the above mentioned. I have been sold on radio, etc., since I was 11 years old and collect every knowledgeable radio book I can get hold of. I would be most grateful if you can help me out.

Warren Dyer
25 Bronwyn Street, St. Albans
Christchurch 5, New Zealand

CW

I have followed the incentive licensing bit somewhat casually but have to ask, "What is all the furor about, anyway?" Is it truly possible that the chance of being reexamined in some relatively elementary theory and being required to send and receive CW at the blinding speed of 13, or even 20, wpm has the whole fraternity shook up? If this *is* a fact, it suggests to me that many amateurs have: (1) lost pride in accomplishment, (2) have no business in the hobby anyway, or (3) worse yet. . .both! Ergo, in my honest opinion, ham radio would be the better off without them. The feeble excuses of "no time," "too old," "can't study," etc., leave me cold. I have raised a family, am working full time on a second-career job (23 years in the navy), am taking an extensive correspondence course and considering additionally some college night school. Incentive? You better believe it! I *want* my license, my rig, and all that goes with it, and I can tell you here and now, they're going to have to take it away from me! Maybe others don't care, but as for myself, the idea of earning something has a great amount of appeal, including an Extra class ticket I picked up in 1954. As far as I can remember, this cherished bit of wallpaper, at the time, offered *absolutely nothing*, promised nothing (I already had Class A), except a large measure of satisfaction in being able to do it.

Except for those who have a physical handicap, anybody who wants a license (any level) and has guts enough to work for it, can get it. Those lacking in this attribute and content to be second best, will, as always, sit on the sidelines moaning and groaning that they are being discriminated against and wait for somebody to give 'em something for free. Well, fellows, have fun. It's cold and lonely out there, but you'll have plenty of company with the rest of the second team.

You may well ask if I belong to the ARRL. You bet I do! I have been so affiliated for over 30 years and I know where responsible, demonstrated leadership for amateur radio may be found.

Gene R. Cate W4GEF
3647 Huckleberry Street
Memphis TN

Is this the familiar if-I-did-it-so-can-you syndrome?

. . . Ken

CW Not Anachronistic

Thanks to Wayne Green for the kind words for CW in the April issue of 73. I do not know Wayne's authority for the statement: "I know that the military uses it very little any more." *Very little* is not defined, but I assumed it was approaching the insignificant.

I do not agree because my information acquired over more than 30 years of being closely connected to the Navy's communication-electronics is probably closer to the real facts than Wayne's. (The Navy was still military the last time I looked.) I am in a position to know that there are still a large number of messages being moved by CW each month over Navy circuits (or else the reports to headquarters in Washington are being gundecked). Several hundred radiomen are being qualified each month in CW in service schools. In addition, Speed Key Certificates are being issued each month. Talk to Navy radiomen who have been on distant deployments and you will learn that it is not uncommon to have to resort to CW as a last ditch mode when TTY and voice circuits go out. True, other modes carry a large part of the traffic these days, both in military and commercial circles, but CW remains the old, reliable standby when others fail.

It is still my professional judgment that people should not rush out and buy lilies for CW's funeral. They may need them for their own first.

Lester Harlow WB6ZNW/W4CVO
5015 Cape May Avenue
San Diego CA

The Navy fought off airplanes and aircraft carriers for more years than anyone thought they could. . .perhaps they will be able to hold onto CW as long as battleships.

. . . Wayne

Ham Exchange

In the past months I had some nice, some very nice experiences with Ham Hospitality. In the middle of May, we had a couple of days off school, and I was invited to New York by 4X4FN, who showed me around town (around city, sorry). We had a real nice party with hams at his house, and also at YO2BOs, where I had the chance to meet a couple of American and foreign amateurs.

My second very interesting experience took place the first week of April. I was invited to Purdue University by CP6DG and CP5FQ, and had a great time too, of course!

I am an exchange student in the states until August 1970, and do not have any relatives here, and in my case, Ham Hospitality is doubly nice, and I am thankful to 73 for having had the idea and having put it in practice! I hope many other hams will be able this way to experiment and enjoy international friendship.

If anyone is in HB9 land, my address is Susi Christen, En Brochat, 1093 La Conversion, with

the phone number (021) 280504, I would be very glad to serve as a guide and do everything possible to make everybody feel at ease.

Susi Christen HB9OE/W4
International House J.S.U.
Jacksonville AL

So There!

73's needle is stuck! Still harping against incentive licensing! It is here; let us face it! I speak now to the 73 staff.

For your own benefit, I suggest that you reread and reanalize Subpart A, General, 97.1, Basis and Purpose.

Amateur radio is not a *right*; it is a *privilege* to be earned; granted us under the control of the FCC by our government.

This continual harping reminds me of the story of the old hound sitting on a burr, howling in pain and just too damn lazy to get up.

I too, was very disturbed when incentive licensing was first proposed; then I reread 97.1 and decided to try and do something about it.

I am a stupid old ex-farmer and I obtained my first amateur license in 1964. In September 1968 I made the Advanced class on the first try, but I failed the theory on the Extra. One year later I again took the examination and made Extra. If I can do it, anybody can. Why bitch? Sure it is work, it takes time and study; but what is a hobby, if it is not something to consume some time? There is also a lot of satisfaction in achievement; try it. I held a radiotelegraph First back in 1932 under the Dept. of Commerce; but that elapsed in 1935 and was never renewed. I admit it helped me with the CW part and was also a factor in entitling me to a two-letter call; but I feel that any General today can at least make the Advanced – which has nearly all the privileges of the Extra.

I was glad to see the Callbook list license classifications. I know of one Technician who immediately disappeared from the 75 meter phone band, and heard of one Conditional who sold all his gear rather than submit to reexamination.

Now you are starting to bitch about paying $9 for a five-year license. Bet you spend more than that on 807s or golf or bowling or fishing and hunting. The Canadian boys now are paying $10 a year for their license. I would like to see them boost the license fee on the 10-4 boys up to $50; maybe that would take the hobbying out of it and return it to the business enterprises for which it was originally intended.

H. C. Swanson W0LZ
193 20th Avenue SW
Cedar Rapids IA

Maybe everyone who doesn't think the same way you do should be lined up against the wall and shot.

. . . Ken

Upgrading

I found Wayne's April editorial very easy to agree with. The ink on my Technician class license is barely dry. If I may, I will make a comment on the difficulty of the written portion of the exam. Admittedly I will fairly soon be one of those EE college graduates that Wayne mentioned. The material might make up a fair hour quiz for junior level EE students. As a text of technical competence, it is trivial.

CAMP ALBERT BUTLER INVITES
HAM RADIO ENHUSIASTS OF ALL AGES
TO TRY FOR YOUR
GENERAL CLASS TICKET

THIS SUMMER! OUR 11TH SEASON

STUDY INSTRUCTION LEADING to GENERAL ADVANCE and AMATEUR EXTRA LICENSE

This co-ed Amateur Radio Camp, Y.M.C.A. owned and operated, can accommodate 60 campers. There is no age limit. We have had campers from 7 through 74 years of age. It is very helpful if you can copy 5 wpm or have a Novice or Technician ticket, but it is not necessary. Time is divided between radio classes in code and theory and the usual camp activities, such as swimming, archery, riflery, hiking, etc. Golf privileges are included at the beautiful New River Country Club course.
Entire staff consists of licensed hams who are instructors in electrical engineering in some of our finest colleges and universities. Camp opens August 1 and closes August 15th. Tuition of $200 includes all camp expenses: room, meals, notebooks, textbooks, and insurance. Send for our brochure.

RG 196 AU 50 ohm teflon coaxial cable. Outside diameter .080" RF loss .29 db per foot at 400 Mhz. Silver plated shielding and conductor. Used for internal chassis wiring, antenna coupling, RF coupling between stages, etc. Random lengths from 35 foot to 150 foot. Colors: black, red, brown, blue, gray, orange. Regular price- 23¢ per foot. Our price 5¢ per foot $3.00 per 100 ft.
455 Khz ceramic filters type BF-455-A. These filters will help to sharpen the selectivity of most sets using 455 Khz IF's. Use across cathode bias resistor in place of a capacitor, or in transistorized sets, across the emitter bias resistor. Impedance is 20 ohms at 455Khz., DC resistance is infinite. Impedance increases rapidly as you leave 455 Khz. Plan your own LC filter circuits at very low cost.
10 for $1.00 25 for $2.00

TOROID POWER TRANSFORMERS

T-2 This toroid was designed for use in a hybrid F.M. mobile unit, using a single 8647 tube in the RF amp. for 30 watts output. Schematic included. 12 VDC pri. using 2N1554's or equivalent. Sec. #1 500 volts DC out at 70 watts. Sec. #2 -65 volts DC bias. Sec. #3 1.2 volts AC for filament of 8647 tube. Sec. #4 C/T feed back winding for 2N1554's. 1¼" thick. 2¾" dia. $2.95 ea. -2 for $5.00
T-3 Has a powdered iron core and is built like a TV fly back transformer. Operates at about 800 CPS. 12V DC Pri. using 2N442's or equivalent. DC output of V/DBLR 475 volts 90 watts. C/T feed back winding for 2N442's. $2.95 ea. -2 for $5.00

ORDER AS MODEL 703 @$18.95 PPD FROM:
HI-SPEC, PO Box 387, Jupiter, Florida 33458

Several years ago Uncle Sammy sent me to thirty-eight weeks of electronics school at Treasure Island. Not many of the graduates would have to live with the license manual very long to pass the General. The same can be said about the graduates of junior college and community college vocational electronics courses.

The problem of cheating is very real. Probably the best answer is one suggested by radical Wayne Green: To have three witnesses present to administer the test (and all mail order tests).

I also feel that the Novice test should be renewable with a fee for renewal, but not for the original license. Also, that the Novice and Technician should be held concurrently.

I also have some thoughts on the invective, I mean incentive licensing, issue and the stupid butchering of the bands which I won't go into here, but there is one thing which might help. Since the FCC, with considerable prodding from Congress, is going to raise the license fees from $4 to $9 to help defray the cost of the operation of the government (what are our taxes for?), why not charge the $9 for renewal of the same class license, but retain the $4 for new licenses or upgrading to a higher license. This would put incentive into incentive licensing.

Techs on 10?

A few weeks ago I sat down and wrote 73 about my feelings on Techs getting part or all of 10 meters so they would be able to get the code practice needed to pass the General. Well, after reading Wayne's editorial in the April issue I again feel I must say something.

Referring to his "Solution to the Code Problem," I would like to give you an idea of what the club I belong to is doing. First, let me say that I am the president of this club and have only been a member for the last year.

I was given code practice by an oldtimer here in town who wanted to get new people interested in amateur radio. After a year and a half as a Novice, I was about to give up on the 13 wpm. At that time I heard the club was going to give code and theory classes so the Techs in the club could upgrade their licenses. I informed three other people of this and they too were welcomed (two were Novices and the other had no licenses at all).

Out of this club of about 20 there was not one Tech who was even interested enough to take the time to attend those classes.

Now, 9 months later our club again decided to give code and theory classes; as before, not one Technician even showed up. Still we were able to give 11 Novice tests and all were passed.

My point is this, all I hear is how the code is stopping some good hams from using the lower bands. If they were the least bit interested in putting a little effort out they could have those rights.

As for giving the Techs 10 meters I would go along if (and only if) it was for CW only. They say this is the only band they can practice on.

I would say if 10 meters was opened to Techs, there would not be any more CW on it than there is on 6 meters today.

Joe Dinger WA9YZD

Repeater Shortcut

Why make repeaters that come down to audio? Why not heterodyne the input to a high i-f, and then back to an output frequency. There are thousands of TV translators which utilize this mode of operation and some legal FCC-approved FM translators as well! (Broadcast FM.) (There are also some illegal broadcast translators working the FM bands that I know of.) Heterodyne microwave systems are very common.

So why not make up a ham repeater that operates the same way. It is easy to tap the amplifier stages to allow squelch cutoff or some such control of the output. The power consumption is less, and the ability to keep the signals sounding better is to be desired.

I'd like to know if anybody in the country is using a pure rf translator. Also, in comments re rules, I think we should keep them flexible enough so we are not ruled out of using translators as opposed to repeaters. Translators are easier, and generally less trouble.

Art Brothers W7NVY
Grouse Creek UT

Gil Boelke W2EUP has built and operated an all-solid-state translator that is completely portable. 73 is pushing him for an article on it. (For the benefit of other readers, Art Brothers was associate editor of FM. His recent request to the FCC for abandonment of Docket 18803 in favor of a new, more realistic docket has been receiving favorable official comment.)

. . . Ken

The Students Net

Various quarters of the amateur community take pride in the supposed courtesy of hams. Perhaps this often seems apparent in the way our bands sound under certain conditions, but I now feel an obligation to express my dismay at having to debunk this rumor.

During the month of May, many college campuses closed or went on strike, in protest to the invasion of Cambodia and the deaths at Kent State. It was natural that the strike leaders, needing some way of communication, and students at various campuses, needing information, should turn to amateur radio. Thus, the National Student Information Net was formed, expressly for the dissemination of information between colleges and into regular broadcast channels, at the campus radio stations. The net leaders checked with the FCC, and were in violation of no regulations, although many people did not agree with some of the information passed on the net (such as strike committee phone numbers, press releases, etc.).

Yet, throughout the operations of the net, on vaious frequencies (depending on band conditions), there were numerous jamming stations who attempted to impede operation of the net. Repeated statements of legality, allowal of breaking stations to express their dislike of net operations, and calling the FCC did not help. It was necessary to call the FCC every few minutes in order to have them attempt triangulation of the offending jammers. Tape recordings were made by net stations to help identify these illegal operators.

The melange of QRM was enough to fill a mental ward. Among the stations was "Big Ben," who whistled a tune familiar from church bells;

PEP's SPECIAL!
CIRCUIT BOARD COLLOSSAL

Loaded with components up to $100.00 value. Bought out one supply house—FIRST come—FIRST served!

All Different! All Complete! First Line Units!

If you don't feel that you got your money's worth—full return guaranteed.

3 DIFFERENT GROUPINGS TO CHOOSE FROM

GROUP A – **Actual Value $15.00 – PEP Price $1.25**

SAMPLE A-1: 200 diode – 7 transistors – over 50 resistors – complete with board.

SAMPLE A-2: Four I. C. Mounting Blocks – 3transistors – over 25 resistors – complete with board.

GROUP B – **Actual Value $20.00 – PEP Price $1.75**

SAMPLE B-1: 8 I. C. Mounting blocks – over 50 resistors – 32 transistors – over 30 diodes – complete with board.

SAMPLE B-2: 32 transistors – over 100 resistors – capacitors – over 15 diodes – complete with board.

GROUP C – **Actual Value $50.00 – PEP Price $4.50**

SAMPLE C-1: 22 in-line I.C.s – over 75 diodes – 20 trans. – over 50 resistors – capacitors – complete with board.

SAMPLE C-2: 22 in-line I.C.s over 50 diodes – over 50 resist – capacitors – complete with board.

"Whistler's Father," whose tunes were fascinating due to the way SSB changes harmonic relationships in music; a phone patch putting a busy signal over the net, several stations tuning up for hours on end, and KØIKB who called CQ on the 80 meter channel for hours on end, despite the fact that the rest of the band was quite clear and our constant telling him that the channel was in use.

Indeed, if courtesy on the ham bands were to be enforced, one could make a fortune selling wouff honggs to use on the lids who persisted in causing QRM to this net. None of the net operators interfere with MARS nets, but the corrupted "patriots" on NSIN with their QRM have shamed amateur radio more than any ARRL publicity campaign could make up for.

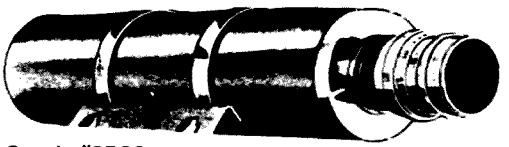
Fred Goldstein WB2ZJQ
President/trustee WA2YXQ
Passaic NJ

At the present time I am listening to the National Student Information Net on 75 meters. This is a net carrying information between college campuses on the student strikes now being held around the country.

For the last half-hour this net has been subjected to the worst heterodyning I have ever heard in all my years as a ham. A number of hams have been deliberately trying to jam this net. Their methods have included broadcasting pure carriers, music, and CW, etc. In addition to being illegal, this sort of action can in no way be tolerated either by the amateur radio community or by our American society as a whole. The survival of our society depends in a large part on the continued free exchange of ideas and accurate information.

I am a college student (at MIT), and though I'm not in support of the strike, I'm in 100% support of the right of these fellows to operate their net with the same respect and cooperation of other hams that any other amateur net receives.

I hope I never again hear such a display of immaturity and irresponsibility on the part of any amateurs and I also hope the amateur community as a whole will join me in reaffirming the high standards and long history of service of our hobby.



Stephen D. Umans K8ZBE

As I write this letter, I am very much angered at the actions of one individual whom I had the occasion of hearing tonight (May 11, 1970). I was listening to the Student Information Net on 20 meters when KØPMS started a QSO directly on the same frequency as the net. He was asked very courteously to QSY several times by the net control station; however, this was ignored by this individual. Repeated efforts on the part of the net control station to contact this individual were ignored, until he finally came back once to launch his attack. I only wish that I had recorded the following sequence on a tape recorder. This individual enlightened us on his philosophy for conduct on frequency usage. He claimed that his license had written on it that he was *assigned* this frequency and that he had every right to be there. He went on to say that this philosophy of his worked for him for years.

I take no stand on the issues discussed on the net, but I will take issue to this flagrant action on

the part of KØPMS. If people like him are allowed to do such things I can see nothing but a dim future for amateur radio.

Gregory Niemyski WA1EMG

One good way of punishment would be for all amateurs to note the callsigns of the offending stations and boycott them in the future. A ham license is worthless if there is no one to talk to. . . . Ken

Not All Bad

I have been interested in amateur radio for a long time. However, I used to live in the backwoods and I could never find anyone to help me learn the code or theory involved. As a matter of fact, I could never find anyone who could even tell me that I needed to learn code or theory. Because of this, I never became a ham.

But now, with the formation of an amateur radio club at the college I go to, I have the help I need to obtain my license. Actually, I have been studying for a few years, and while looking for a good magazine on amateur radio, I came across an issue of 73. What a discovery!

I honestly believe that there is not a better ham magazine on the market today. I find it difficult to believe that you can cram a magazine so full of information and not run out of material. One feature which I really like, and which I hope you will continue, is the absence of those cardboard reply mail inserts. The only thing more irritating would be unnumbered pages. Please keep those cards out.

I would like to make a couple of comments on letters printed in 73. First, in the April issue, in a letter from Edgar Wagner, the first sentence in the second paragraph begins, "To a Englishman. . ." The correct wording should be "To *an* Englishman. . ."

Secondly, how about all those snide comments about CB'ers? I will be the first to agree that possibly 80% of the CB'ers operating are either operating illegally or don't know what they are doing and have no legitimate reason for being on the air. But there are some (yes, Virginia, there are some) CB'ers who will only operate legally and who also perform invaluable services. Besides, CB is a very handy thing to have around. Don't knock *all* the CB'ers.

Raymond E. Miller KCQ6239
552 Claremont Avenue
West Chicago IL

Nobody at 73 knocks CB'ers. We just don't condone the illegal practices of some of the

"ham" types. Perhaps, when the FCC opens the 220 MHz segment to the Hobby grade of amateur license (no code, minimum theory), the days of CB misuse will be over for good.

. . . Ken

Who Needs Friends?

I just finished reading Ken's April editorial and wish to express a great big thanks for same. There must be some way of influencing or moving the FCC other than through the ARRL. I was so angry over the incentive licensing escapade that I dropped my membership in the League and do not intend to rejoin.

I got my Advanced ticket, but so what! If I want to work my friends I have to work in the high end of the band anyway, so it seems of actual little value.

I would go all out for incentive licensing if the higher classes could work voice in the top half of the CW portion of the band. This would make much more sense to me, especially since you can work CW over the entire band anyhow. Regardless, who needs a "friend" such as ARRL? Better I should have an enemy, for at least I would be suspicious of him from the very beginning.

We believe it is time for the amateur radio operator to be represented by a national organization directed by and for the members. It would be nice if the League could fill the bill, wouldn't it?

. . . Ken

Here's $50 – I think I will go the whole route. Send me 73 for "your life or mine."

I think a series on building a serious VHF station would be great. Start with 2m complete antennas, converters, transmitters, etc. Then do 432. I really think this would be a goldmine of articles. Get the "Big Boys" to write some of them.

Marshall P. Williams WA5UNL
5429 46th
Lubbock TX

73 has the articles, but they aren't in the form of a series. Might not be a bad idea to think about it, though. Anybody else have ideas?

. . . Ken

Self-Destruction?

I first wish to say that I have subscribed to every Ham publication at one time or another, and I have found yours to be the most interesting. Secondly, I wish to comment on the Great Battle that your magazine has been carrying on for the past several years. I have off and on been reading the letters in your columns and found that most believe that one cannot stand in the middle of the road in the struggle with the ARRL and the fight for individual representation. I believe that the Great Battle has been stalemated by this radical and unfortunate position. Neither side can claim that they have all the answers, or all the supporters, and it seems to me that it is foolhardy to divide a minority into two entrenched factions that are sworn to battle to the death for God and amateur radio. I suppose that if the peoples of the world were split into two groups, then this method would be effective in

deciding which group were to survive. Unfortunately, we are not the world's population, but a minority; and, when the smoke of battle clears, one group or the other will not stand victorious, but both defeated. The remaining group will have been battle-tested, but small, weakened, and obnoxious in the eyes of our "don't make waves" government's opinion, will win their battle without firing a shot. Think! If you wished to destroy a group and their holdings, what better way than allowing the group to destroy itself. No, I am not screaming conspiracy; I am screaming *idiots*. You are the self-righteous lambs, not with the dignity of being led, but taking yourselves to the slaughter.

Judge your position by its results. What are they? Most of those opposed to the ARRL's position wished it to be destroyed and a new and better organization to grow from its ruins. Has this happened? Those who believed that the ARRL's proposals would strengthen the League and elevate the amateur's technical ability should also pause to reflect. Has this happened?

Change! Is that what you want? I sincerely hope so as that is certainly what we are getting. The direction of the change is the unfortunate thing: the decay of a once-proud entity always is unfortunate. I would have much preferred the status quo to suicide, but now I – and others like me – am being dragged along and forced to watch this abomination. Now nothing can stop this change; the impetus is too great. We (and I mean *we*) still can determine the direction of this change. The one great question is how can we accomplish reconstruction and redirection from the throes of self-destruction? After taking inventory the deplorable fact exists that the League is the only recognized agency in existence that still maintains any manner of respect or authority with the government. We need a liaison, and the League must be that liaison. That, regardless of your viewpoint, is a hard and inescapable fact.

What we must do, what should have been done in the beginning, is to change and support the League, not destroy it. If the effort that was put into demeaning the League had been channeled into reconstruction and reenforcement from the beginning, this situation could not have existed. Anarchy cannot exist, if isolated. We should have usurped their authority, isolating the anarchists and making them impotent. We cannot do that from outside the League: it must be accomplished from within. We must regain control of the League and its position of authority and use it for the common good.

The recipe to success is deceptively simple. Join, keep informed, participate, and vote! Above all else we must have patience! Although it may appear like our problems are of a fairly recent origin, starting perhaps around the time Wayne Green brought them to light, you couldn't be more mistaken. Vital organizations don't decay overnight. We lost the League years ago, and it may take years to reshape it again. The question that we all must answer in truth to ourselves is a basic one. Do you want to be a "ham," I mean do you really want to be a "ham" enough to forget about your investments in amateur gear and take time to think and be proud of being an amateur radio operator? Pride? Maybe it is the thing that stabs you in the back when a new acquaintance of yours invites you

mark 2
oscillator/monitor

- makes an audible tone to monitor the RF of any CW transmitter from 10Mw to 1 Kw & 100Kc to 1000Mc, using only an 8" pickup antenna.
- can be self-triggered for code practice or the testing of solid state components and circuits.
- aids in tuning up & testing RF oscillator and power circuits.
- 4 transistor, 2 diode circuit, speaker, tone adjust, AA pencell, test tips, 8" ant., & magnetic base.
- cabinet is 16 gauge black & clear anodised aluminum, 3.4 x 2.3 x 1.2"
US made & guaranteed for 1 year.

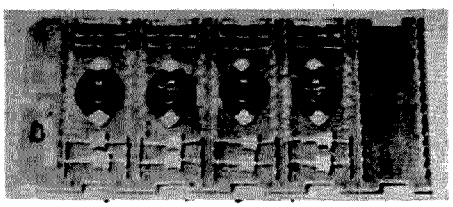
TRANSISTOR AUTO RADIOS

Brand new factory packed automobile radios, vintage around 1961. 12 volt neg. ground. No choice of models. The exceptional sensitivity of an auto radio makes it superior for use in car, boat, truck, camper, etc., where you are quite a distance from xmtr location. This is also the best kind of radio to use with short wave converters. Each with large original equipment hi-fi speaker. Some with noise suppressor kit. High quality, most made to sell in the $100 range. A real "find."

$15.00



Above equipment on hand, ready to ship. Terms net cash, f.o.b. Lynn, Mass. Many other unusual pieces of military surplus electronic equipment are described in our catalog.

BOX 1, LYNN, MASSACHUSETTS 01903

over to see his ham setup and shows you his CB rig, the thing that's inside that old receiver or transmitter that you keep around for sentimental reasons, or the thing that makes you see your junk as "junque." Pride, or whatever name you can give to that sense of being that once united and made the League strong, we need now more than ever.

If implementation of your wishes is your problem, maybe the new structures, the roundtables that SSB brought upon us and the profusion of traffic nets, can be made to perform double duty. There is always someone on these nets and roundtables who has a definite opinion on how things ought to be run up there in Newington. If you agree with him, why not tell him to do something about it. Support him with your proxy and give him the backing he needs to put some of that QRN he's generating to some good use. Take some of that spare time at the end of the net to inform the net about what is happening inside the League, instead of filling the time with comments from the push, hold, and talk fans.

If you still need some incentive, first think about 11 meters, and then swivel around in that chair, look at your "ham" gear, and try to think of someone you can sell your rig to when you don't have any bands left to operate on.

N. Gary Boucher W3GNR
411 Waupelani Drive
State College PA

Forgotten

We are sorry to learn that Ken has led such a sheltered life and missed the dynamic and growing southeastern section of our country in both his travels and attention. May I bring 73 up to date with the repeater operation in our state?

The Carolina Repeater Society (WB5PLN) operates two repeaters near Columbia which covers a 60 to 70 mile radius to mobiles in the central portion of the state. The 6 meter repeater has a 52.76 input and 52.525 output. The 2 meter repeater has an input of 146.34 and an output of 146.94. Both repeaters are a split system. The two receivers are located on a tower near Edmund and are connected to the transmitter located near Gaston by separate 450 links.

WA4SSJ in Greenville operates a similar repeater with an input of 52.76 and output of 52.525. There is also a .34/94 two meter repeater on each side of us – Augusta, Ga. and Charlotte, N. C. All these systems are open repeaters. We welcome travelers and invite their use of our repeaters and invite our neighbors in the southeast to communicate with us.

Ken Adams K4MOC, President
Carolina Repeater Society
Columbia SC

All it takes is a spokesman. We at 73 don't publish repeater info until we get it. If you know anyone who wonders why his repeater never gets

listed in our directory, ask him how long it has been since he sent the particulars to 73. Squeaky wheels get greased better and more frequently.

... Ken

Bravo!

I have enjoyed reading 73 in the past, but the recent staff additions and the fine FM articles have done the trick! Here's my $12 for 3 years. Keep up the good work in FM! Although I do not always agree with the editorial policies of 73, I find it *does* provide the opinions not found in other ham magazines. 73 is not afraid to "speak up" and I admire that. Bravo!

John S. Cole WA8ZPF
488 Fourth Street
Manistee MI

You may be interested in reading the following comparison and rating of 73 and *QST* magazine, along with my comments and suggestions.

(Ratings are 1—5)

	73	QST
Tech. Articles	3.5	5+
Editorials	5+	2
Ham Ads	2	3.5
Interest	5+!!!	3–4
Overall Rating	5	3.5

As you can see, I prefer *QST* for articles for a purely technical nature, but as far as editorial glimpses of our hobby I prefer your magazine. Although many of your articles start on a technical theme they seldom "follow through" into a thorough discussion of the subject. However, your editorial columns are to be ranked with the best of other nonham magazines such as *Saturday Review* and the like – especially Dave Mann's *Leaky Lines*, which is one of the finest pieces of literary opinion work I have ever seen. I rate K2AGZ and his column an extreme 5+!!!!!

One more important rating:

Humor: QST-0.5 ... 73-5+++++!

HAM'S QSO SAVES LIFE IN COSTA RICA

Radio-TV Men Watch as 'Mercy Mission' Drama Unfolds

Thanks to the efforts of a few conscientious hams, an alert newspaper, and a mercy-minded airline, a Costa Rican hemophiliac was saved from what doctors said was "sure death." The incident was a highly dramatic example of the importance of ham radio to a community.

The international "mercy mission" was touched off by Long Beach, California Amateur Nate Brightman K6OSC, who received an urgent message from a Tuna clipper fishing off the coast of Mexico. The vessel's radio operator, Rodriguez Beeche TI8RBL, was relaying a message from Dr. Herman Weinstock in San Jose, Costa Rica, asking Brightman to arrange an immediate shipment of Hemophil, a blot-clotting agent produced by Hyland Labs, a Glendale, California firm.

Dr. Weinstock related, via ham radio, that his patient, 24-year-old Ed-

A helicopter furnished by the L. A. Sheriff stood ready in Glendale to pick up a vital serum and rush it to a waiting Pan-Am jet at the L. A. International Airport.

arrived at the airport with the drug, about a half-hour after the Pan-Am jet's scheduled takeoff.

The Hemophil was delivered on time, and the patient responded so well to the medication that an operation

dent from the outset. Dr. Weinstock's messages were phone-patched out by his ham brother, Salomen Weinstock TIZWC. Louis D. Arce TI2LA provided postdelivery information from San Jose for Stateside newsmen. Pablo

CITIZENS PROTEST HAM RADIO TOWER

While a ham in Long Beach worked to save the life of a dying man in another part of the world (see headline, this issue), another amateur in a neighboring community was being legally "assailed" by public-spirited citizens who were protesting installation of a 55 ft tower.

Tom Rothwell, an Extra class ham of Los Alamitos, California, had applied for and received permission to construct the tower, but residents in the area appealed the decision. The city council called a public hearing after reading a petition signed by 63 townspeople.

In defense, the amateur radio operator stressed the importance of ham radio during natural and man-made disasters when other means of communication are disabled. He asserted, logically, that his installation could prove vital to the community.

After listening to protests from most of the 45 people present at the hearing, City Attorney Jack Parker ordered a continuance so the council

uardo Castro, required an immediate operation for bleeding ulcers and would have "no chance for survival" without the coagulant.

In contacting Hyland Labs by telephone, Brightman learned that the firm's supply of the drug had been depleted, and that the earliest time a new batch would be ready was the following morning – but not quite in time to catch the only available plane for Costa Rica.

Recognizing that a certain amount of pressure would be required to coordinate the various elements of the situation, Brightman called the local newspaper, the Long Beach Independent Press Telegram, and asked help in getting the drug to its destination.

With the news media tuned in, the ball started rolling, as TV channel 9, radio station KFWB, and the Press-Telegram provided heavy publicity. The newspaper called Pan-Am World Airways' New York office and obtained the authorization necessary to hold the Costa Rican flight long enough to get the drug aboard. Then it arranged for a Los Angeles Sheriff's helicopter to fly the drug the 20 miles from the lab to the airport as soon as it was produced.

Newsmen and TV cameramen were standing by when the helicopter was found unnecessary.

A 73 reporter talked to Nate Brightman and learned that several amateurs had been involved in the incident. Fonseca TI4PF and George (TI2IT) also provided message handling and phone-patch services during the overnight intercontinental emergency.

Food for Thought: Without a similar facility, Long Beach operator Nate Brightman might not have been in a position to put into motion the chain of events that saved a life. If Brightman's neighbors had been as short-sighted as Rothwell's, what would have happened to the hemophilia victim in Costa Rica?

DARC President Visits U.S.

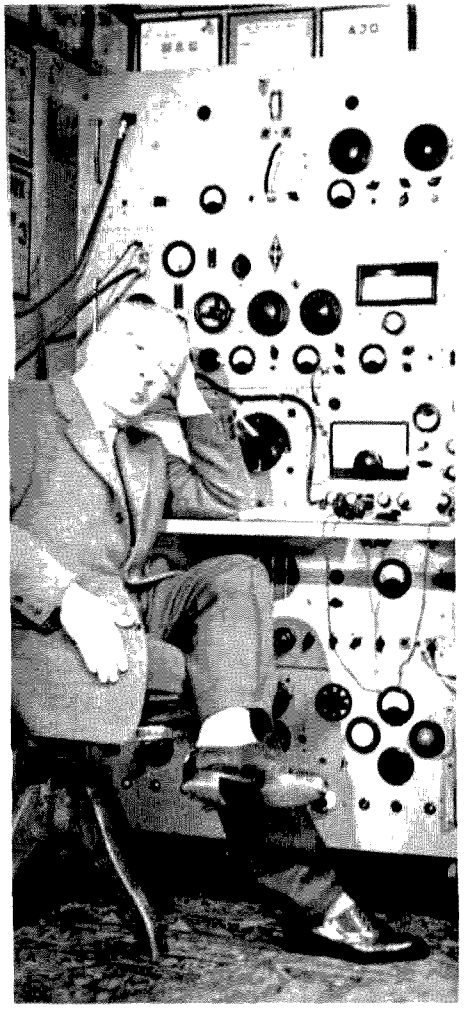
Karl Schultheiss, the president of the DARC, will be visiting the U.S. in late August and early September, staying with WA2ELA in Dewitt, New York and traveling from there. Perhaps your club could arrange for Karl to visit? Write to James Kirkgasser, 105 Haddonfield Place, Dewitt, N.Y. 13214 and make arrangements.

Polish Ham's Death Felt Worldwide

by W4WFL

Amateur radio lost another pioneer with the recent passing of Jan Ziembicki (SP6FZ).

Active as early as 1921 with the callsign TPAR, Jan's interests embraced all aspects of amateur radio. He was one of the earliest experimenters on the VHF and UHF frequencies and by the mid-thirties was experimenting with television transmission.



Following the allocation of international prefixes, Jan operated under the callsigns SP5AR and SP1AR until the outbreak of World War II. After the war he was unable to obtain a license until the mid-fifties when he returned to the air as SP6FZ.

Jan quickly established himself as a leading DX'er, garnering most of the important awards, including DXCC and WAZ.

His rig was completely homebrew and constructed from a wide variety of surplus, commercial, and homemade parts. It covered the bands from 80 meters through 450 MHz, phone and CW.

Jan was a doctor of engineering and in recent years he was associated with the University of Warclow where he was involved in the design and application of electrical and electronic devices for use in cardiology and other areas of medicine.

His passing is a heavy loss to family and friends and to amateur radio.

Scholarship Set for Student Hams

The Foundation for Amateur Radio, Inc., a nonprofit organization headquartered in Washington, D.C., announces its intent to make the annual award of the John Gore Memorial Scholarship for either graduate or undergraduate study. The Scholarship pays $500 for the academic year. Upon reapplication, it is subject to being renewed for succeeding years.

Licensed radio amateurs who intend making a career in electronics or related sciences may now request the application for covering the academic year 1970–1971. Requests should be addressed to Chairman, Scholarship Committee, 8101 Hampden Lane, Bethesda, Maryland 20014. The award will be made during the month of December 1970. Receipt of applications for the award must be received by the close of business on 31 October 1970.

To be eligible for the award, applicants must have completed at least one year in an accredited college or university and must be enrolled in a course of studies leading to a degree. They must also be radio amateurs holding a valid FCC license of at least a General level.

MARS OPS GET SSTV DEMO

The enlisted men's service club at Andrews AFB was the scene of a slowscan TV demonstration in which 18 Air Force MARS operators were in attendance. Dr. Theodore J. Cohen (W4UMF) reviewed the broad field of slow-scan communications, beginning with a discussion of bandwidth–time considerations, and continuing on through equipment construction, color transmission, and computer processing of slow-scan pictures. A live demonstration of a slow-scan monitor, using taped pictures as a source, topped off the evening. Among those in attendance was the recently appointed Chief of Air Force MARS, Capt. Jan P. Huggins (WB4ONK). Col. Paul Ridenour (W8KDS) hosted the meeting.

Dr. Theodore J. Cohen, W4UMF, addressing Andrews AFB Radio Club.

DX NEWS

by W2NSD/1

GUS SWAMPED. . .ALMOST!

After three days of operation on Geyser Reef as AC0A/GR, the high winds and heavy rain took their toll. When two drums of gasoline floated away Gus had to give up temporarily and make the hard trip back to the Comoro Islands for more gas. The reef is very difficult to get on and there is only a very small place for a station to be set up. . .and even that gets splashed

Trevor 5W1AR has been active from Western Samoa, bless him. He is living in the same house as 5W1AZ and, I believe, using the same rig. This is the rig I used when I visited there back in 1966 and racked up a couple thousand contacts almost overnight. Trevor was my first contact with 5W1. . .the problem was that the previous op had a small circle of friends that he worked, and that was about it.

Market Reef has been busy

More activity from Qatar (pronounced gutter) as Tom MP4BHH brings a rig down to Dave MP4QBK and leaves it with him in late June. AP2KS is weak, but in there on 20.

5T2ITU was doing well during a May contest, though Mauritania is not extremely rare these days, what with 5T5ADand lists by PY2PE. Even old familiar calls like KM6 seem rare these days. KM6BI (Glen) called in the other day to say hello, my first KM6 is ages. KW6EJ (Jack) has moved down to the Caroline Islands now and can be heard reguaarly as KC6EJ. Those strange calls that turn up during contests make the ITU prefix list handy (73,July 1970).

Around The Amateur World

Excerpts from IARU Region I News

CZECHOSLOVAKIA. Czechoslovakia has nearly 3000 amateur radio stations of which about 500 are club stations with registered operators and shortwave listeners. Besides the activity on HF and VHF bands there is amateur radio activity in connection with fox hunting, high-speed code contacts and the construction of electronic equipment. The *Central Radio Club of the Czechoslovak Socialist Republic* has an office in Prague which carries out the work of the QSL Bureau, certificates and awards and contest organization. The Novice license allows operation on the 1.8 and 145 MHz bands with a maximum input of 10W. The full license has three classes: Class C, 25W input on restricted bands; Class B, 75W input on all bands and all types of emission, and Class A, 300W input on all bands using all types of emission. The first Czech DX club was recently formed by a group of amateurs from Slovakia. Dr. Harry Cincura OK3EA was elected club president and OK3IR became secretary. OK3-DX club has 28 full members and 37 others, to promote interest, a weekly DX bulletin (DX-NT) has been established. The editor of DX-NT is Joko Straka OK3UL. Dr. Cincura was a member of the Czechoslovak delegation to the 1969 Region I Conference at Brussels. This news of the formation of OK3-DX was sent by Tibor Polak OK3BG.

EAST AFRICA. Please note that the address of the RSEA QSL bureau is Box 5681, Nairobi, Kenya. In addition to exhibiting at Electra 70 the RSEA will again be providing communication facilities for the East African Safari.

GERMANY. During 1969, 179 reciprocal licenses for operation in

by the larger breakers. The propagation conditions, as accurately forecast in 73, were dismal on 15 and 10 meters and forced Gus to spend most of his time on 20, holding forth on 14,000.000001 or so. The phone operation was around 14,106 kHz. Conditions were a bit better on his second stint, fortunately.

ZB2A (F Gordon) has been adding to the 20 meter pileups on weekends. He recently decided, with the help of his QSL manager (WB9WBU), to try the "list" technique. It worked well and the contacts went a lot faster than the usual super-tailend system, with stations tailending each other for minutes at a time to be sure and be the last to transmit.

While operating from JY1, I never let the tailenders get going on me, but I did run into problems with downright callous operators trying to get through no matter who they had to squish to make it and no matter who I asked to transmit. Split frequency helped a bit with this, happily I thought to try getting some of the stronger signals to make up lists for me. This was very fast – the fastest of all.

SVØWU puts through a regular signal from Rhodes, which counts for the Dodecanese Islands, a separate country from Greece. Ike works for the Voice of America there on Rhodes.

9H1G (Joe) and 9H1CE (Bert) have been active recently from Santa Lucia in Malta. Bert is a bit weak with his SB33 and dipole, but Joe runs 300W into a three-element beam and has a substantial signal. 9H1CD is also active. Another rare one in the Mediterranean area is Morocco. (CN2BS (Chris) is doing what he can there to help. OD5BZ (Bob Adams), by far the most active station in Beirut, has now packed up and gone back to W8-land. We will all miss his strong signal. By the way, if you find yourself in Beirut (and who doesn't find himself in Beirut now and then, right?) don't miss the Al Barmaki restaurant. Bob showed me this one and it is great!

again. . .third time since it passed muster as a country. This time ops are OH2BH (Martin) and about ten others – the call is OJØDX. QSL to Angerroti 8B17, Heisimkin 32, Finland.

There are many hints that some OHs will make it down to ZA for the first operation from there in a long time. . .or is it ever? DL7FT was collecting money to go, but nothing came of it and no answers to letters to Frank asking about his plans, the money, etc.

King Hussein has been off the air for a few weeks obviously as a result of the headline problems that have developed in his country. The QSLs have been coming through the bureaus for his contacts and mine from JY1. If you haven't gotten your card yet you either haven't QSL'd to Box 1055, Amman, Jordan as requested, or you have been too cheap to send an envelope to your QSL bureau, or both. I have a personal and vested interest in His Majesty solving his political problems. . .I want to get back to Jordan for another visit perhaps this winter, and I am hoping that an introduction from the King will help me to talk with powers in neighboring Arab countries so I can sell amateur radio.

VR4CG George has been active from Honiara (Box 310) in the British Solomon Islands. I think he must be rare because he is the first VR4 I've heard, ever. He was on 14.231 with a nice S7 signal and not-too-big pileups at 1300Z on a Sunday.

WØMLY (Dick), who runs the Antenna Mart out in Rippey, Iowa, doesn't miss much going on, and has a new one up his sleeve that he hints about, but won't explain. He claims it is new, will count, and that he has the license for it. All he needs is the money, but with collections for DL7FT to go to ZA, Gus to go all over the place, and such, he decided to sit still for a while. Donations have been noticeably harder to get lately, a phenomenon attributable to what some call the "Miller" effect.

ZZ2ERS (PY) says QSL to WB9BWU. ZV7APS did well in the contest and is also from Brazil.

Now that Robby is relatively inactive, even the 5Z4 prefix has rarefied. Chuck, up in Kitale, has been active as 5Z4KM, easing some of the pressure. But I noticed when I operated from 5Z4ERR a couple years back that the pileups were substantial, and again a few weeks ago when Gus stopped there, the pileups were going again. 5Z4 is "medium rare."

LZ1KSZ (Michael) in Stara Zagora (I thought I would mention the city since it has 100,000 population and I'll bet you've never heard of it) started DXing when he was 15, seven years ago. QSL to Box 73. He tells me that the active LZ1s in the club are DG, DK, DO, DL, DJ, DZ, KP, KGZ, KFZ. Most of them are on CW.

VR1L (Bob) is on Ocean Island, one of the Gilbert & Ellice Islands. He most definitely QSLs, through W6NJU. Bob was a new one for me. I missed him one night when he was in QSO with VR1). . .wouldn't that be a nice roundtable to break?

The activity in Turkey has been growing recently, after many years of very sparse contacts. QSL to TA3HD (Hal) vis K3ZPU. Father Moran 9N1MM is on quite often, if you think to point your beam up thataway. He has a good signal and is active enough, along with Jinny, to keep Nepal only medium rare. Afghanistan doesn't come through all that often, but I've contacted a number of fellows up there recently. Probably the most active for me has been YA1GNT (Ed).

Are there any valid contacts being made with China? I doubt it. I suspect that the next BY you hear should be ignored. . .but I'll bet you'll work him "just in case."

I see that K1OTA (Ken) is expecting to be active from 3A2 (Monaco) July 23–27, C31 July 30–Aug 4, LX Aug 6–9, 9H1 Aug 13–16, 3V8 (Tunisia) Aug 21–23. That sounds like a ball.

Germany were issued by the DARC office of International Affairs. All applications for permission to operate in Germany should be sent to DARC International Affairs, Muhlenstrasse 27, D-5601 Doberg, German Federal Republic.

INDIA. During the recent CCIR Plenary Conference held in New Delhi, the Amateur Radio Society of India held a reception for delegates. Among those attending were Brigadier L. King VU2AK, and M.G. Karnik VU2CK, president and vice president of the ARSI. The visitors included RSGB president Dr. John Saxton, and Jack Herbstreit HB9AJI, director of the CCIR. During the meeting a special station (VU2ITU) was in operation.

REPUBLIC OF IRELAND. The address of the official QSL bureau managed by the National Society, the IRTS, remains as 24 Wicklow Street, Dublin 2. Visitors to the republic may obtain, without charge, a temporary license for up to 30 days' operation in any year. Applications should be sent to Department of Posts and Telegraphs, (G.B.) Radio Section, Hammam Buildings, O'Connell Street, Dublin 1. Applications should be made at least one month before the proposed visit. The following information should be given:

1. Date of commencement, and duration of visit.
2. Band or bands to be used.
3. Type or types of emission to be used.
4. Brief details of equipment.
5. If mobile, give make and registration number of vehicle.
6. For fixed operation, give QTH.
7. Holders of UK licenses should send photostat copy of *first page only* of their license or their mobile license.
8. European licensees, send photostat copy of license.

Visiting amateurs will only be afforded those facilities to which their home license ordinarily entitles them.

The Sierra hamfest will be held Saturday, August 22, at Mormon Station Historic State Monument at Genoa, Nevada just off Hwy 395 south of Carson City.

Illinois

The Vermilion Country ARA will hold its 2nd annual hamfest on August 30, 1970 at Douglas Park in Danville, Ill. There will be door prizes, hourly drawings, and the main drawing at 3:00. Donation: $1. For further info write Tom Stover WA9ULI; 1611 N. Vermilion; Danville, Ill. or call 217–446–3293. Talk-in, by the way, will be on 3.925, 7.260, 50.4, and 146.94 FM and 147.3 FM.

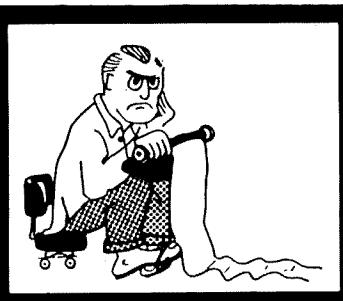
England

GB3WRA, operated by a group of local radio amateurs, will be active from the 24th annual Wycombe show on the Rye. High Wycombe, Bucks, England, Saturday, September 5. Operation will be on all bands, 160–10 meters. All contacts will be confirmed by a specially printed QSL. The Wycombe show is a typical English country show which displays all aspects of English country life. Any Ws visiting the area will be especially C. Butcher G3FSN. 70, Hughenden Avenue, High Wycombe, Bucks, England.

Nebraska

Again this year the Lincoln, Nebraska Amateur Radio Club will operate a special events amateur radio station 24 hours a day from the Nebraska State Fair Grounds in Lincoln, September 3 through September 9, inclusive.

DX contacts will automatically be QSLed via bureaus. Stateside contacts must send SASE to WØYOY, 3030 Shirley Court, Lincoln, Nebraska 66507. A special QSL card for the occasion will be used.



Pennsylvania

The Mt. Airy VHF Radio Club, Inc. will hold the annual picnic and family day on August 9, at the Fort Washington State Park in Flourtown, Pa. In the past, hundreds of hams have attended this event.

A big feature is a drawing for door prizes, some of which are donated, and some purchased by the club. There is one drawing for prizes of interest to hams, and others for women and children.

Washington

THE PUGET SOUND COUNCIL OF AMATEUR RADIO CLUBS will again issue a Washington State operating achievement award signed by Governor Daniel J. Evans, for contacts made during Washington State Amateur Radio Week, September 6th through 13th. Out-of-state amateurs must contact ten Washington hams, and in-state amateurs must contact 20 other Washington hams during this week. Send list of stations worked, their locations, dates of contacts, your name, call, and address to Puget Sound Council of Amateur Radio Clubs, 12306 80th Avenue East, Puyallup, Washington 98371.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

The ITU Problem

Those of you who have been following my editorials down through the years will find this piece a bit repetitious, but perhaps thought provoking.

The most important result of my visit to Jordan was not the contacts that I made or even the setting up of that country with an amateur radio service, it was the vote at the ITU that amateur radio will have from Jordan. Amateur radio has scant support from the African and Asian countries and needs every vote it can get from them.

The source of our amateur frequencies, as I am sure you know by now, is not the Federal Communications Commission, but the International Telecommunications Union in Geneva. The ITU has little organization in itself, being made up mostly of representatives of the many countries of the world who get together in Switzerland every so often to agree (and disagree by way of footnotes in the articles of agreement) about all matters having to do with international communications.

The last ITU conference which was scheduled to take up reallocations of the amateur bands was in 1959. Both John Huntoon and I had the honor of attending this conference as representatives of amateur radio. The only other such representative from our country was W1BUD, but he was very "sick" at the time and was unable to participate much. The allocation of shortwave frequencies was set aside at this conference, leaving the fate of our bands to the next conference which was expected to come along in the mid 60s.

The emergence of many African nations upset the balance of power in the ITU, shifting it from the European countries to the African–Asian countries, with the result that further conferences of the ITU were blocked at every turn by the Europeans. When you consider the decimation of the amateur frequencies proposed by some of the African–Asian countries at the 1959 conference, the delay has been most fortuitous for us.

Since no country has been able to develop its electronics and communications without a healthy amateur radio population to provide the technicians and engineers, we have a terribly important message for all the emerging and developing nations. . .push amateur radio and push it hard or else be prepared to take a back seat to those countries that do. It is reasonable . . .it is logical. . .and the proof is plain to see: those countries that have encouraged amateur radio have been able to develop because they have engineers and technicians to provide the communications which are the most basic ingredient of development.

I do not believe that it is any accident that the industrial development of most countries is parallel to the number of radio amateurs they have licensed. Obviously it is of extreme importance to get this message to the leaders of the emerging countries. Has anything much been done to do this? The answer, as you again know, is a sad no. . .little has been done.

A man of stature is needed for this task. . .one who can not only get in to see the rulers of these countries, but one who will be listened to when he gets there. It is extremely unfortunate that Herbert Hoover Jr., the past president of the ARRL, did not undertake such a goodwill and promotion trip. The money was there for it – $100,000 was set up for just such a thing – but for some reason it never came about. About the only other radio amateur of such an international stature is Senator Barry Goldwater, but I'm afraid that his work in Washington may preclude his setting out on the long and difficult trip that is called for.

I hope that His Majesty King Hussein will not mind my mentioning him, but he quickly grasped the importance of amateur radio to the development of his country and moved immediately to set up the hobby there. I am in hopes that through his understanding and friendship I will be able to visit some of the other neighboring Arab countries and try to set them up with a healthy and expanding amateur service. This will not only help the countries involved, but it will give us a good guarantee of the votes that we desperately need in Geneva.

Unfortunately, I have neither the time nor the money to even make a decent try at promoting amateur radio in but a small percentage of the countries where the effort should be made. I enjoy this sort of thing, but until subscriptions come in a lot faster and advertisers consider it a

lot more important to support 73 than they do now, I'm busy paddling upstream for all I'm worth just to stay in one place. As soon as I rest for a day or so the falls just downstream come closer, if you'll excuse the metaphor.

I hope that I can mention the ARRL at this time without some readers feeling that I am tearing it down. The ARRL, for all of the good things that it is doing, is not yet perfect. . .I hope that even the most prejudiced Leaguer will agree to that. This means that there are areas where some improvement can be made. Is it destructive of me to point these out?

Since the ARRL has set aside $100,000 for the defense of our amateur frequencies it seems logical to me that it is up to them to make a definitive move in this direction. Their position as the national society for the U.S. and their control of the IARU would seem to automatically elect them for this position. They have expended $37.586.48 (according to the last ARRL report) towards this goal during the last few years, though I haven't yet seen an accounting for it. If you are able to get an accounting I would appreciate your passing it along to me. I'm sure that this money was not just spent on vacation trips by the HQ brass. But I'm not certain. Unaccounted large sums like that worry me. No public corporation would be able to hide something like that from its stockholders, so why should ARRL be able to sweep it under the carpet.

The problems at 73 have prevented me from getting over to visit and talk with the current secretary general of the ITU. I did manage to talk quite a bit with two previous secretaries general and found them both very interested in the idea of developing amateur radio in the backward countries as a key means for getting technicians and engineers in those countries. I proposed that the ITU establish a simple set of amateur radio regulations for application in small countries and this was in the works with the last secretary general. This would in essence put the prestige of the ITU behind amateur radio and help our hobby to expand. I am sure that this could be set in motion with the new secretary, if someone could sit down and put the proposition to him.

The ARRL board of directors has been peculiarly silent about this responsibility of the League. This is hardly a problem that can be ignored or just not faced because it is difficult. Since HQ seems to have done little on its own initiative, it is up to the directors to force the HQ boys into action. And it is up to you, the members, to force the directors into action. The next time your director shows up at your club, ask him for an accounting of the $37,000. . .HQ certainly hasn't kept that much money a secret from him. . .and exactly what the League proposes to do about getting votes at the ITU. . .and, incidentally, why he did absolutely nothing at the last board meeting about getting even one man in Washington as a lobbyist for amateur radio!

As long as the League has a net loss each year, even though it is minuscule, it is simple to avoid both tax problems and demands from the members for added services such as public relations, lobbying, etc. The loss last year was, as usual, quite small, less than $50,000 on a turnover of well over $1.5 million. It was also quite unnecessary. There is some $500,000 sitting around doing very little except turning into dollarettes that could be used for the promotion and furtherance of amateur radio. There are also any number of ways that money could be saved, as I am sure your director will have to admit if you corner him, which would provide funds for the benefit of our hobby.

While you are asking your director questions, there are a few others that you should bring up. For instance, if you read the annual report you will find that the publication expense for QST last year ran an average of $32,666 per month. That may not sound too bad, considering the costs of business today, but I will tell you that I could put out the same number of copies with the same number of pages for just about half that. $15,000 a month or so is being blown somewhere and you deserve to know who is getting all that money and why.

Part of the loss is because QST is just a bit bigger than the other three amateur magazines. This little bit extra means that QST will not quite fit on the modern presses and thus has to be run in smaller sections. This increases the cost greatly.

Undoubtedly QST's change to doing their own typesetting will bring about some savings for this year over last. But why was QST the last ham magazine to put in the IBM typesetting system? 73, by the way, was the first. Ask your director about this.

You might ask your director why QST is ten years behind the times in the paper it is using too. The ARRL could save thousands of dollars a year by changing to a more modern type of paper. The paper manufacturers have not been sitting idle; they have been inventing lighter and better papers, with no sacrifice in opacity, and they cost a lot less than the old-fashioned papers.

Just think what good could be done with the nearly $200,000 a year that might be saved in the publishing of QST! A small fraction of that would keep a man on the road visiting foreign governments on the behalf of amateur radio on a year round basis. Another fraction would buy us publicity and promotion for amateur radio in the top mass-circulation magazines. Ask your director about this and listen very carefully to the explanation.

Again, please let me emphasize that the above is written in the spirit of constructiveness, recognizing that no organization, not even the ARRL, is absolutely perfect and above improvement. You should recognize that it is unlikely that

(cont. on page 81)

Repeater Update

At a recent FM forum, Bob Peterson K2IEZ asked me why I never included in the periodic repeater directory systems that required the use of continuous subaudible tones. I emphatically told him – and the others present – that I would not list such repeaters because they could not realistically be considered as open repeaters. Continuous tone – unlike tone-burst entry – involves some rather precision tone generation equipment. Levels for continuous tone (PL) are unusually critical, and even an error of 0.5 Hz will keep the user from being repeated.

Well, since the forum I've had a change of heart. FM isn't quite the new thing that it was a few years ago. More and more repeaters are going up, and they're going up more and more frequently with overlapping coverage areas. In many cases, use of PL is the only practical means for avoiding interference with adjacent repeaters.

So, while I would still like to discourage the use of PL (because PL itself discourages newcomers from getting a taste of the fun of repeater operation), I will include PL repeaters in the directory, regardless of frequency of operation. The only requirement for directory listing is that the PL frequencies must be included along with the operating frequencies.

If you operate a repeater that welcomes transients, write the particulars on a sheet of paper or a postcard and send it to 73 right away. We are currently preparing a repeater directory "update," and want to make it as accurate as possible. We want to list all open repeaters, on 6 meters, 2 meters, or 450 MHz. But hurry – we don't have a lot of time.

The Busiest Check Around

When I returned from the Orlando hamfest, 73 gave me a $10 check as reimbursement for some out-of-pocket expenses I'd incurred in Florida. But rather than cash the check, I kept it in my wallet for a few days.

Then, when Betty Daniel WB6AOF, a friend of mine from California, spent nearly $10 to mail me an airmail package from my home town, I just endorsed the 73 check and mailed it to her.

Betty's husband, Fred Daniel W6NQS, owed Don Milbury W6YAN $10 for a crystal purchase Don had made. So, since it was Fred's money that had paid for the mailing of my package anyway, he asked his wife to sign the check over to Don–which she did.

But Don was interested in getting a subscription to 73 Magazine, so he endorsed the check and sent it back to its home in Peterborough.

The story doesn't end here, though. That crystal that Fred bought from Don was really from Wayne Green's Handie-Talkie. Fred is owner of Communications Specialties, the company that put Wayne's Handie-Talkie on frequency. Since Fred had paid for the crystal, he sent Wayne a bill from Communications Specialties for $10. Guess what check was used to pay that invoice.

A Free Plug (It's a Pun)

If you've recently purchased a Galaxy FM-210 2 meter FM transceiver, you've no doubt learned that it comes less microphone. The unit has a PL-68 receptacle built into the front panel and is designed for a high-impedance ceramic or dynamic mike. When Wayne and I bought our FM-210's, Wayne had the foresight to order a couple of push-to-talk mikes from Meshna Surplus (Box 62, E. Lynn, Mass. 01904).

These mikes warrant mention because they sell for only $5. They are attractive, hand-held jobs with built in push-to-talk switch and an ample length of three-conductor curly-cord. I rate it as a great buy. The fellows from Meshna say they'll throw in a PL-68 plug, too, if the buyer states the mike is for an FM-210 (while Meshna's PL-68 supply lasts, that is).

Another commodity we picked up from Meshna that should be of particular interest to FM'ers (because of the FM'ers lust for frequency stability) is tunable NPO capacitors. Meshna sells these individually (3–12 pF) for 25 cents, or in "banks" of 24 for $3. The 24-bank array includes five 3–12 pF, fourteen 5–25 pF, and five 8–50 pF. I bought a batch of these to replace some rather questionable "original equipment" variables.. (The banks, by the way, are difficult to separate into individual capacitors).

Repeater Users!

Last chance to correct 73's listings for your area. A new *repeater update* is being prepared for publication in an upcoming issue. If your repeater has not yet been listed, mail complete info to Repeater Directory, 73 Magazine, Peterborough N.H. 03458. Include repeater call, area served, tones required (if any), essential data (narrow or wide, times of operation, etc.), input and output frequencies. Do it now!

73 Repeater Slide Presentation

73 would like to make up a tape-and-slide presentation for use by radio clubs across the country. If you'd like your repeater featured, send us a few representative 35 mm slides with explanatory or descriptive information. We'll combine yours into the "carousel" and work your information into the story.

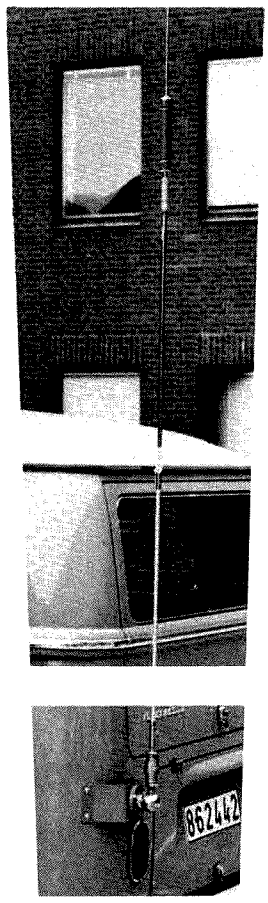
Leaky Lines

1 DANIEL LANE, KINNELON NJ 07405

By unofficial count, and with some willfully inaccurate exaggeration thrown in for good measure, I estimate that there have been approximately 673,492 references in the press respecting pollution of the environment. Of this, about half has dealt with air pollution, slightly less with water impurification, and the remainder with adulteration of food, indiscriminate spraying for insect pests, noise, and other miscellaneous types of environmental deterioration. The least mentioned item in the list has been noise pollution, meaning the clatter of garbage trucks, automobile horns, compressed air drills, blasting, fire sirens, sonic boom, city buses, cats serenading from back-alley fences, and Puertoricquenos playing bongo drums and guitars on the sidestreet stoops of the city after midnight.

In very few instances can I recall any mention of a specific form of atmospheric despoliation with which we radio amateurs are vitally concerned; namely the pollution of the airwaves in the form of unwanted hash on the station receiver. Apart from ordinary, everyday QRM and QRN, we are forced to contend with a veritable smorgasbord of obstreperous sounds, any one of which is guaranteed to drive you stark, staring mad in a trice, or a couple of trices. There's ITV, from those verdammte 15,000 Hz horizontal TV oscillators; IDD, from misbehaving diathermy devices; INS, from malfunctioning neon signs in bars and grilles; IVW, from the hot ignitions of Volkswagens and other foreign compact cars; IBI, from broken insulators on power poles; IEB, from electric blankets; IRT, from refrigerator thermostats; ICO, from can openers; ISM, from sewing machines; and even IRCBPBASORASLH, interference from rectification caused by poorly bonded aluminum siding on ranch and split level houses! We have no shortage of supply; noise in this society is as ubiquitous as was horse manure to an earlier age, before the proliferation of mechanized modes of conveyance. But, at least the manure nourished entire generations of English sparrows. Of noise, very little good can be said!



Everybody is jumping on the antipollution bandwagon! President Nixon in his state-of-the-union speech last winter said that his Administration is determined to come to grips with the problem of our air and water. The late Rachel Carson, in her books *Silent Spring*, and *The Sea Around Us*, dealt in great detail and depth with pollution's awesome effects upon our ecology. And the redoubtable Ralph Nader has been wielding his cudgel against the unscrupulous culprits who have been sullying out food supply with harmful chemical additives. The conservationists campaign against our traditionally lackadaisical apathy, and it is difficult nowadays to find a single newspaper or magazine in which the subject is not discussed. But hardly a soul, except some lone, isolated acoustical engineer, writing a monograph for a ceiling tile manufacturer, has seen fit to spell out the dimensions of the noise menace in all its truly perilous proportions. In addition to all the other types of noise pollution, something must be done about the lousing up of the radio waves.

By this time we all recognize the power of small but vocal minorities. Once the public becomes aroused and angry... once the sleeping giant awakens... there's very little he cannot accomplish. Indignant nature lovers, in a tizzy over plans to build an atomic power plant on the majestic Hudson at Storm King Mountain, raised incredible furor. Even disreputable looking, bearded, guitar-playing folk singers joined the crusade. Despite a company sponsored survey which showed that only very minute thermal changes would occur, and guaranteed only minimal deleterious effects upon the fishes of the river, the antagonists have so far successfully withstood all efforts to establish this installation, and it remains an unfulfilled dream to this very day...a monument to the irresistible power of public indignation. The righteously wrathful spirit of Carrie Nation rides abroad throughout the land. And woe betide any would-be opportunist who stands in its path!

When TVI occurs and customers complain, manufacturers of TV sets supply free components to clear up the problem. Why are they permitted to omit the highpass filters at the factory? Because it's an economic factor, of course. But, isn't it ridiculous to have to deal with each and every situation on an individual basis? Well, just suppose the problem never materializes on a high proportion of the sets? For each of these trouble-free sets the manufacturer saves the cost of such preventive components, resulting in a not inconsiderable aggregate total.

(cont. on page 63)

mount that mobile right!

The right kind of mobile installation will result in bigger signals, better operator safety, and more fun in hamming on the road.

Joe Carr K4IPV
511 New York Avenue
Norfolk VA 23508

After several years in the automobile radio field and almost ten years in amateur radio, the author supposed that he had seen just about every atrocity that can possibly be committed in the mobile mounting of a piece of auxiliary electronics equipment. This assumption is constantly proved wrong by new installations that range from the tragic to the immensely funny! The truth is that a little forethought and some basic craftsmanship will prevent most of the headaches usually cited as objections to mobile operation.

Placement of Unit

For this discussion we will define "main unit" as a transceiver, receiver/transmitter combination (such as was popular a few years ago), or other unit. Specifically excluded for the time being are the various remote control schemes commonly associated with trunk-mounted FM equipment.

Placement, in some cases, is often the most discouraging pitfall encountered during a mobile installation. Automobile manufacturers have displayed a positive genius for frustrating the plans of all but the most ardent mobile operators. They have designed auto interiors in such a way as to eliminate any possibility of mounting a mobile rig anywhere but in the trunk! Some of the problems encountered in trying to solve this particular pitfall include dashboards with inadequate strength or insufficient mounting space, transmission "tunnels" of odd shape or size, and general lack of room between the accesory panels and the floor.

The main considerations for determining placement are safety and convenience. The rather obvious assumption that excessive reaching while driving can be fatal sets a requirement that the unit be placed within nonstraining reach of the operator (unless, of course, no in-motion operation is contemplated). It is also a good idea to make sure that lacerated

knees and torn stockings don't result from the installation. In a one-car family, such can be the spark that ignites a disruption of domestic tranquility!

If a dashboard mount is impossible, the transmission tunnel may be adequate. A surprising number of installers overlook this possibility by not knowing that most of the mounting brackets supplied with modern transceivers can be attached from either the top or the bottom. Even if this is not the best method of mounting, a little imagination and a few odds and ends will improve the situation.

Dash Mounted Units

The most usual mounting method is the familiar "U" or channel bracket suspended from the underside of the dashboard. This bracket is fastened with screws to both the dashboard and the mobile unit (Fig. 1). A mistake that is often made is the use of too lightweight a screw. The best are machine screws fastened with a star washer and two nuts. It is, however, not always possible to use this method. If, for instance, the upper side of the dashboard lip is inaccessible, then self-tapping screws are in order. Whichever fastener is decided upon must be substantial enough to hold the unit securely. Lightweight units can be held with a No. 10 screw; heavy units with a No. 12. If a larger screw is required for any particular unit, then there are serious doubts as to the dashboard's ability to support the unit.

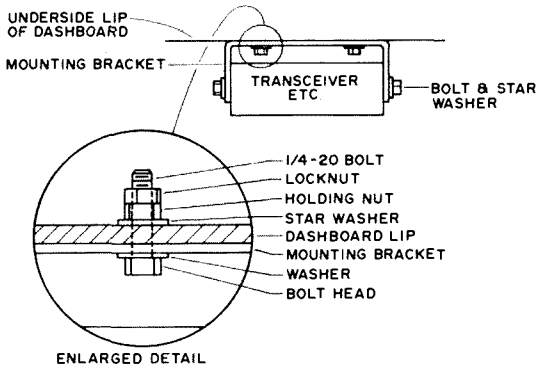


Fig. 1. With lightweight, low-power mobile transceivers, a simple mounting bracket can suspend the unit. The rear of the transceiver can be held with a bracket fixed to the firewall.

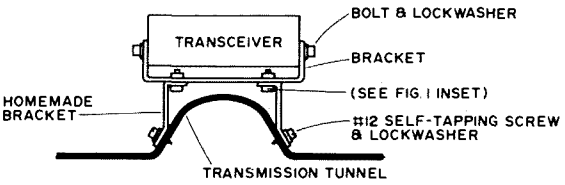
Floor Mounting

If, for any reason, the rig cannot be suspended from the dashboard, a good alternative is the transmission tunnel. As mentioned before, most brackets can be upended and installed from the bottom.



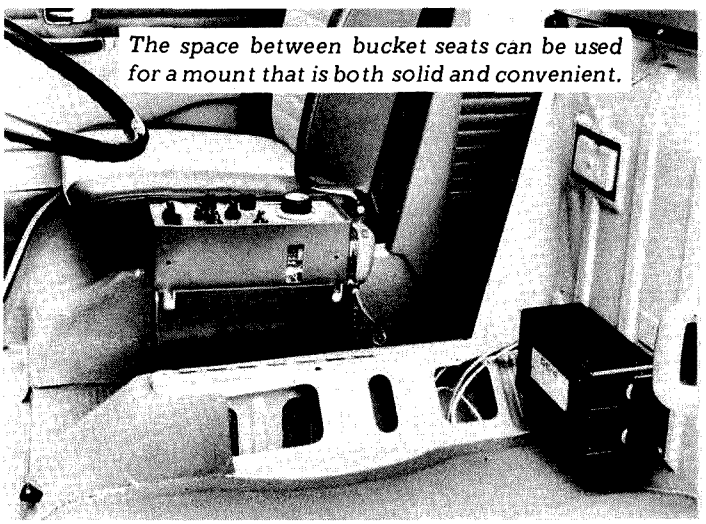


Fig. 2. Since most transmission humps differ in size and configuration, mounting here usually requires a bracket of special design. A little metal work, though, will result in a very effective and solid installation.

Figure 2 illustrates one possibility. The rig may be mounted either horizontally or vertically (perhaps resting against the seat). Again, screws that will bear the load are essential. (If your car has carpets instead of rubber floor mats, DO NOT USE A DRILL to make holes for the screws. The carpet thread will wind up around the drill bit creating a very amusing pattern in your once conservative rug.)

The space between bucket seats can be used for a mount that is both solid and convenient.

In some bucket-seat vehicles such as the van shown in the photos, an ideal installation is the area between the driver's and passenger's seat. Many transceiver manufacturers also produce brackets that result in a sturdy installation yet which permit quick removal of the unit.

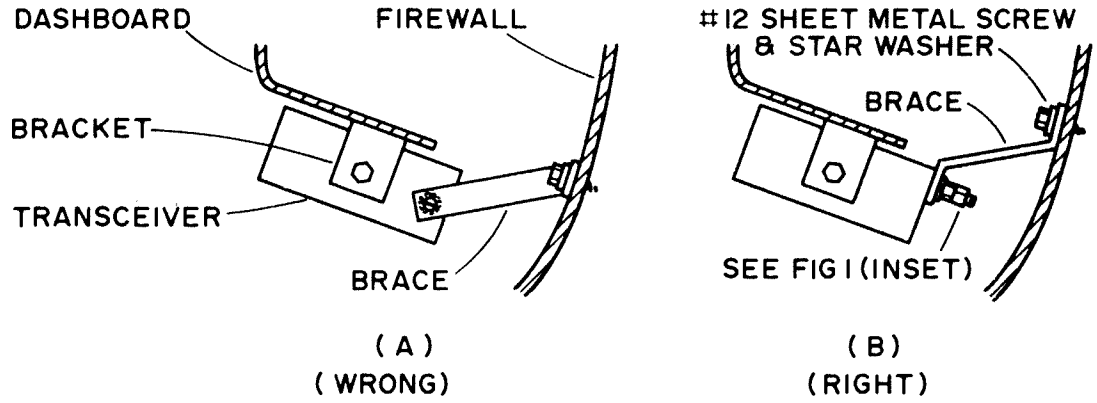

Fig. 3. The bracket at the rear of the unit should be placed near the center of the transceiver's back plate, as shown here. If a single bracket is mounted at the side, an undue strain is placed on the front bracket and the unit can vibrate loose in a short time.

Bracing

Vfo stability, the continued good health of the rig, and some safety considerations depend in large measure on the stability of the installation. It is surprising that some operators will sacrifice the good repair of their unit (vibration plays hob with electronics gear) for the relative ease of a braceless installation. A piece of stiff metal pipe strap, a length of angle stock, or any substantial material can be used, depending on the particular situation. It may, in some cases, be necessary to drill a hole in the rig to provide for such a mount. Some reputable manufacturers overlook this necessity because mobile operations are a second thought. A ¼-20 screw is preferred for this use. Figure 3 shows right and wrong ways to make a brace.

Speakers

With the advent of automotive stereo tape players, there have been a large number of speaker mounting systems introduced that are possibly better than the traditional mobile speaker. These usually can be mounted behind the dash completely hidden from view. Care should be exercised in selection of these units not to obtain one of the door mounting units. Most cars use the door interiors as a rain drain, making it a rather unhealthy place for loudspeakers. Check out auto radio and other stores that deal in tape players. They should have a stock of such mounts. You should remember that your best bet is to have the speaker pointed toward your ears. The audio you'll be listening to is not hi-fi, and you'll need as much intelligibility as you can get.

Antennas

A discussion of antenna techniques deserves a treatment of its own. Such a treatment is given in both the *Radio Amateur Handbook* and the *Mobile Manual*. The only comments appropriate here are a matter of opinion. There should be a definite trend away from bumper mounted antennas. They are a lot less substantial and a whole lot more aggravating than other types. As for the objection to cutting a hole in the body of a car, it is of little importance in most cases. Holes can sometimes be filled at low cost.

Power Considerations

Except for taking care to mount power supplies where good ventilation is provided and passengers' feet avoided, there is not much to mounting power supplies that

With the seat in place (covering the Drake's power supply), the power cables and antenna lead-in are out of sight. The microphone drops out of the way, too, and clips onto the side of the rig. (Probably the most important single consideration with any mobile setup is microphone cable routing. Lack of care in underdash rigs can lead to steering wheel entanglements and other such embarrassments.)

cannot be inferred from the above paragraphs and photos.

Another case entirely is the power supply hookup. Rigs in the CB power class can be hooked up through the auto ignition switch, even though it is *not* recommended. This is accomplished by locating the accessory terminal of either the switch or the fuse block.

A higher power rig (as most are these days) must be hooked directly to the battery with wire heavy enough to carry the current load without heating up or causing an intolerable voltage drop. Remember, a rig that requires 200W of line power will draw almost 17A at 12V. The nature and cost of high-amperage switches makes relay control look better from many standpoints. In general, it is *not* a good idea to connect the power lead to the fuse block. Run it straight to the battery of the battery terminal on the engine starting solenoid.

One often overlooked problem regarding the power hookup concerns the possibility of picking up motor noise transients. All wires that are run through the engine compartment have the potential of picking up noise. Under all circumstances these leads should be dressed away from the ignition coil and its associated wiring. Shielding is also desirable. The shielding braid on the larger sizes of coaxial cable may be of sufficient diameter to handle the current drawn by a low- to medium-power rig.

The long multiconductor harnesses usually associated with trunk-mounted

The biggest problem of vertically mounted rigs is that the operating panels tend to collect dirt. A dust cover will keep dirt out effectively and will reduce the chances of someone spilling coffee or cola onto your new Drake. The inexpensive cover also discourages tampering and accidental knob-bumping.

The antenna warrants a great deal of thought. It should be mounted as far from the road as possible to minimize noise pickup; it should extend as high above the vehicle as practicable. Both these objectives are achieved in this Volkswagen installation, where a special plate is installed for mounting the Hustler antenna away from the vehicle body. This type of installation requires some weatherproofing where the coax feeds the spring base.

installations should never be run down the same side of the car as the normal automotive wiring. The proximity is likely to cause noise pickup by mutual coupling. A more complete treatment of noise problems can be found by consulting the *Handbook, Mobile Manual*, and the author's article in *QST* (July, 1968).

Preparation

One of the prerequisites for any major project is preparation. For a mobile radio installation a good selection of tools is essential. An electric drill with a collection of bits suitable for the uses that will be encountered, a collection of wrenches and other hand tools, and a reasonably good place to work will make the job a whole lot easier. A comprehensive study of the *ARRL Mobile Manual* and appropriate sections of the *Handbook* are both likely to help the mobile aspirant to avoid some of the mistakes that are made all too often. These publications also contain information that will aid in making some of the decisions and choices that inevitably pop up from the very beginning of such projects. . . . K4IPV ■

Amateur Wattmeter for $3.85

. . . tells you your power output from 10 mW to 5 watts, over the range from 160 meters up through 450 MHz

This article describes a very useful gadget for determining the rf power output of solid-state VHF–UHF transmitters in the difficult range to measure, from about 10 mW up to 5 watts. It does not read watts directly; but by a simple comparison of calibrated pilot light brilliance, it will tell you how many watts you are putting out, to within less than 5%. It allows you to check power increases and estimate your efficiency quite close.

Principle Involved

We'll start right in with this part because, while this unit is not by any means a "trick," it does not read rf directly. You first light a pilot light as a good dummy load, matching it into the rf tank circuit of your transmitter by the normal means, also noted here.

You then switch on a second bulb of the same type by means of a battery, controlling the light output with a $1.30 wirewound potentiometer in series, as shown in Fig. 1. This pot must be previously calibrated in milliwatts, as by the method of "volts times milliamperes equals milliwatts." You then match the brilliance of the bulb lit up with rf or its dull glow at some 18 to 25 milliwatts if you're just getting your transmitter going, and read the watts on the wattmeter dial. It's astonishing how well it works, how repeatable it is, and how you wouldn't be without it once you build and calibrate it.

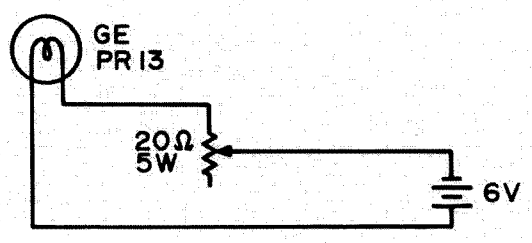

Fig. 1. The circuit supplies the brilliance "standard" for comparison. When the "standard" lamp is mounted adjacent to the dummy load, the pot permits variation of the standard to match the load. If the resistance is panel-marked in watts, a good power indication is achieved.

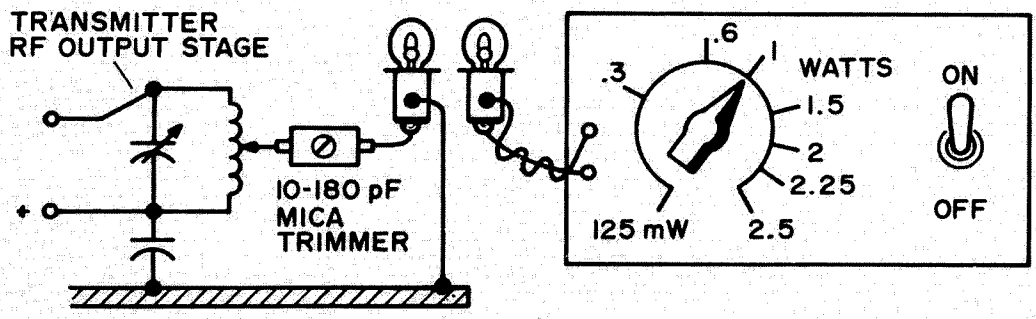

Fig. 2. A series capacitance loads the rf indicator for comparison. The capacitance value will decrease inversely with frequency increases.

Brilliance Standard

Figure 2 tells almost the whole story at a glance. You can, of course, put as much calibration on the dial as you have time for. It is quite important to orient the bulb filaments in the same relation to your eyes for best matching. There isn't much in back of the panel except one 6V battery which can be obtained in any hardware store.

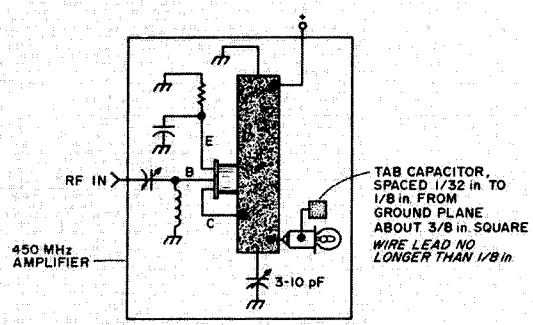

Fig. 3. Matched pilot light load for the UHF version.

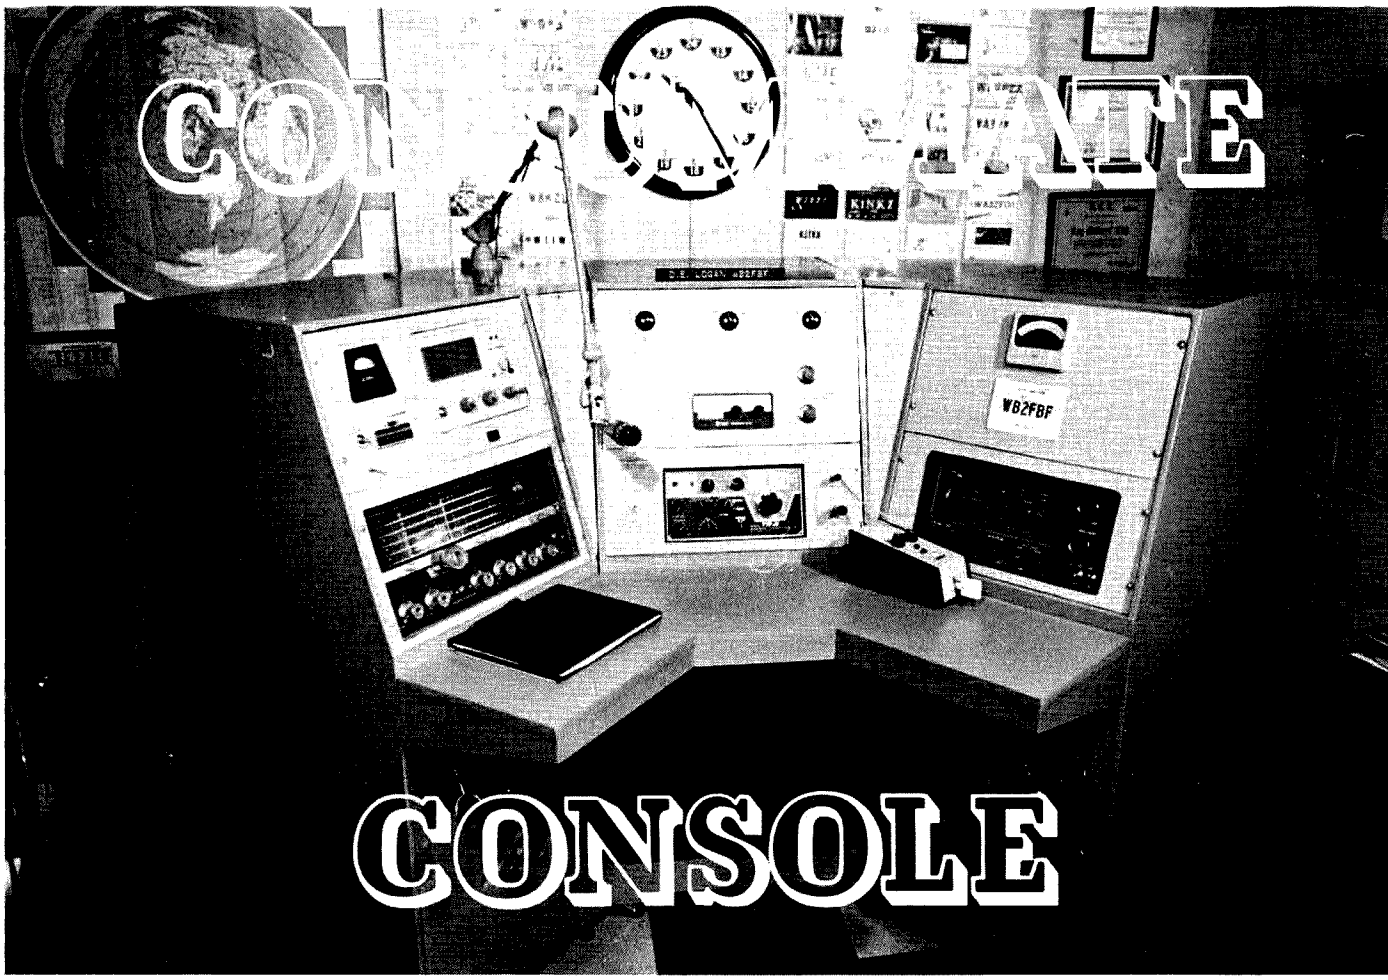
RF Matching



Not that it is particularly critical, but be sure and note the need for a large range of series capacitors for the rf pilot lights as you go up in frequency. This can be seen clearly in Figs. 2 and 3. The block diagram, Fig. 2, shows a 6 meter setup. As you go up in frequency the series capacitance drops. A good matched load on 432 MHz can be obtained as shown in Fig. 3. I sometimes remove the tin base from the bulbs, but this is not an absolute necessity. It is important to vary the amount of coupling, and thus the series capacity, by spacing the tab capacitor closer or further away from the ground plane, as detailed in Fig. 3. You also can use as many bulbs as you can solder onto a tuned rf inductor, even though they don't all light up with the same brilliance. You can match them all up, but you don't have to. Just check the wattage, or milliwattage, of each one and add them up for the total.

The number 48 or 49 bulb, listed at 2V and 60 mA, is rated at 120 mW, and glows dim at about 12 to 15 mW; so it can be used for low-power receiver oscillators, etc. With two other bulbs found in hardware stores, connected and matched to the rf inductor, such as the PR13 (5V at 500 mA), you can read correctly up to 5W. From there on up you're on your own, although a good variable 115V dc supply can be made up to work around 50 to 100W. I generally use a variety of 115V bulbs of different wattage, light them up with rf, and use their rated wattage.

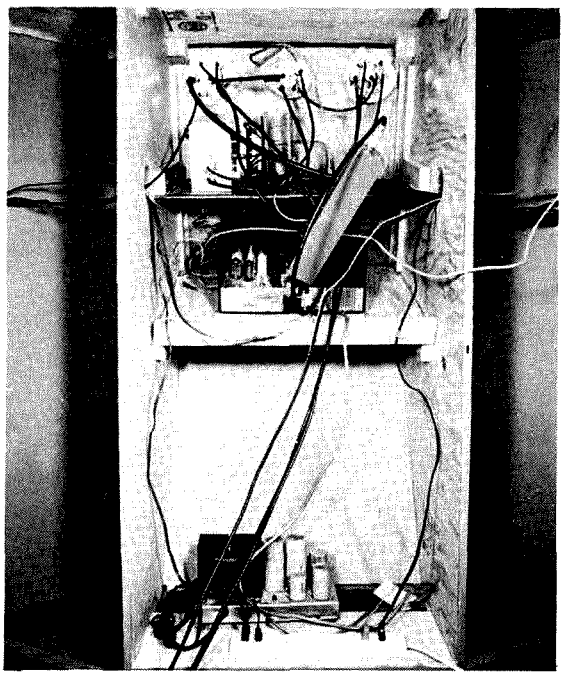
THE CONSOLE

Dee Logan WB2FBF
21 Judith Street
Nanuet NY 10954

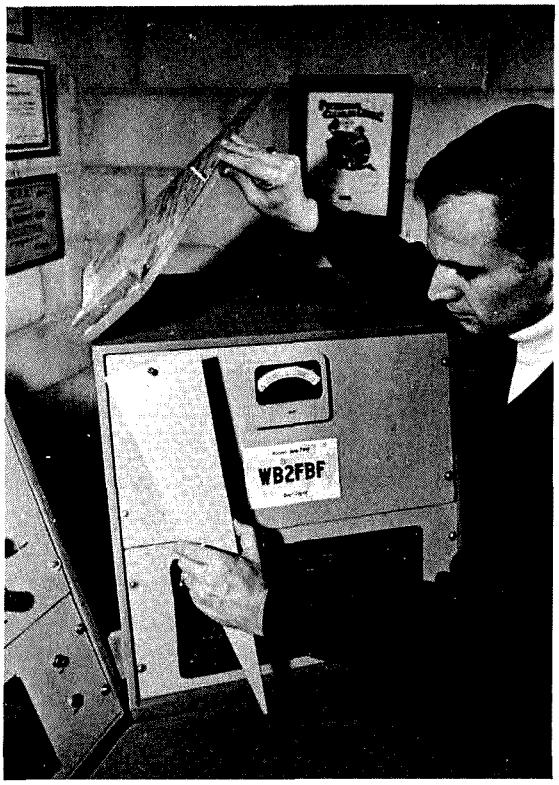
Increasing station efficiency and enjoyment with a broadcast-style console.

Most hams go to great lengths to achieve peak operating efficiency from their station equipment, but seem to spend far less thought on station layouts that could also add to their operating efficiency and enjoyment. If you've been growing irritated with the teetering stacks of equipment and tangled snarls of cable that have resulted from random station growth, you may be ready to get organized via a station console.



I formerly worked in commercial broadcasting as a combination engineer–announcer and realized from first-hand experience that it's possible to run an entire radio station from one operating position. The key is in the console that allows one man to control mikes, turntables, tape recorders and transmitter without leaving his chair. That's efficiency! Wouldn't that same approach be welcome in the hamshack?

Since most amateur radio stations have but one operator, the evolution of the console design can revolve around meeting his specific needs. It will, for example, mirror his operating habits, modes of operation, and personal tastes. The design for a serious DX'er will undoubtedly incorporate features that wouldn't be as important to the more relaxed, feet-on-the-desk ragchewer.



It might be pointed out that any design should result in a dramatic transition of your station from a random collection of individual components into a smoothly functioning system.

Once priorities are established, the evolution of a console system should follow some "noodling" with pencil and paper. Use a little "human engineering." This is loosely defined as calculating the optimum position, size, and motion of switches, knobs, and controls to achieve the most efficient operation with minimum fatigue (or frustration!). This may extend to such subtle points as the color scheme (light colors in greens, blues, and grays are more restful backgrounds).

The station console at WB2FBF evolved after researching what others had done, including K2YIH, who described a similar console in 73 back in November of 1963. Admittedly, a tour of NASA's Manned Spacecraft Center in Houston did a lot to start my dreams about what the station *could* become with the proverbial elbow grease, in lieu of an astronautical budget!

Behind the console panels, neatness doesn't matter quite so much. Large holes in the plywood cabinet sides facilitate cable routing; coaxial switches help to keep transmission lines out of sight.

When the console bays are placed together, there will be large space gaps unless you build special-shaped wood sections like these. They add a professional touch and lend a look of uniformity to the three cabinets.

Basic Design

The U shape of the console is actually formed by three wheeled sections that are held together by a bolted-on operating tabletop, hinged braces in the back, and five-sided top pieces that fill the spaces between the center section and each end. A pair of triangular pieces of Masonite are used in front.

The entire console, when broken apart, is narrow enough to roll through our basement door. Also, the wheels allow the operator to roll the complete unit away from the wall for easy access to the rear. Equipment is arranged in custom-cut panels that slope away from the operator about 6 in. at the top.

The arrangement utilizes the center section for the main operating area, and consequently includes the transceiver, swr bridge, antenna coupler, and an antenna network of coaxial switches. It's possible to quickly switch from dummy load to any of several antennas or to switch in a scope or antenna tuner as needed. The left panel contains the VHF area: Twoer, converter,

rotor control, and SX-111 receiver. On the right is an all-band receiver, ac line monitor and scope (added since the photograph was taken).

Lower portions of the end sections are used for storage of power supplies. Hinged front panels are used as baffles for speakers. The lower part of the center section is left partially open to supply legroom by running a Masonite piece diagonally down to the rear.

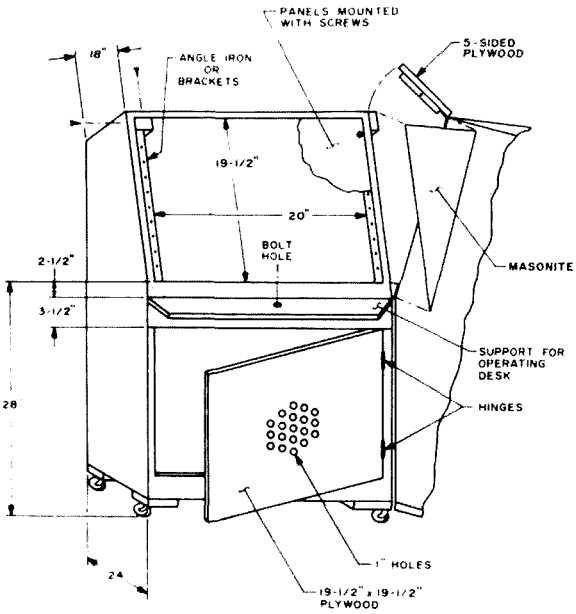


Fig. 1. Sketch shows general construction data for each console bay. Three of these bays form the operating console.

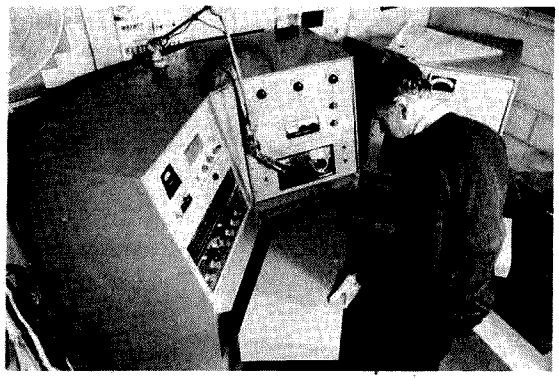
The console sections (Fig. 1) are each 20 in. wide (inner measure). This is an arbitrary dimension and is based upon accommodating the widest piece of equipment: our SX-111 receiver. The console is 48 in. high measured from the floor, with about 3 in. used for the hard rubber wheels that are mounted on pine squares on each corner. The operating desk provides a 12 in. deep writing surface, and is positioned 30 in. above the floor. Each console section is 24 in. deep, but is 6 in. less at the top due to the diagonal slope required for the panels.

Construction

Plywood, pine, and Masonite are the prime materials used in the construction. Interior-grade 0.5 in. plywood is used to form the three main sections. Two wafers of plywood form the sides; pine pieces are used at the bottom and front, held to the plywood by countersunk screws and glue. Use wood filler to cover the screws and sand smooth.



The top of each section is made of a plywood square, with reinforcement under each corner supplied by blocks cut from 2-by-4's. Use plenty of glue, wood screws, and cover the screw heads with filler. A bottom shelf is likewise made from plywood or Masonite.

One detail worth noting is the support for the operating desk. This is formed by making a narrow ledge about 3 or 4 in. deep out of plywood and sandwiching it between the pine pieces across the front of each section. The ledge should be about 27 in. up from the bottom so that when the wheels are added, the total height will be 30 in. above the floor. Be careful not to run this ledge the full width of the section; and cut the ends diagonally since it will be turned on an angle when joined with the other sections. The operating desk is added later and rests on the three ledges, attached by three countersunk stove bolts (one for each section of the console) and wing nuts.

Before mounting the speaker baffle panels on the bottom of the two end sections, drill a series of 1 in. holes in a pattern appropriate for the speaker sizes. Be careful not to splinter the plywood when drilling, and remember to cut into the finished side slowly. I used a circular saw and experiment on a piece of scrap beforehand.

After completion of the three sections, the general shape of the console can be arranged by pulling the individual sections together. The angle decided upon for our console was about 120 degrees between the center section and each end. Locking the center section to each end is done via hinged slats at the bottom rear, and a "trailer hitch" type of overlapping block near the front. Once the three sections are locked in place, measurements can be made for the five-sided plywood pieces that fill in the top and the pair of Masonite triangles for the front.

One thing confronting me in respect to finishing the plywood edges was in locating 0.5 in. wood strips at our local lumber yard. Since I lacked adequate power tools to cut the strips at home, some filler was called for. Cellulose-type filler goes on easily, but is difficult to sand down, so I opted for water putty. This is a powder

The desktop mounts neatly right over the support joists, locking the cabinets into a single three-bay console.

compound that can be mixed with water to produce a paste that can be applied to the plywood edges with a putty knife. When dry, it sands down easily.

Equipment Panels

Mounting equipment in a console of this type suggests at first glance that everything is virtually locked in for the future, but such isn't the case. Unless a console is flexible enough to allow for changes, it will eventually grow obsolete.

I selected easily cut 0.25 in. plywood and Masonite as the material for the panels, though aluminum sheet would provide a suitable surface if direct mounting of equipment on a panel is chosen. A series of shelves is arranged behind the panels and the equipment rests on these with the front protruding through openings cut to size in each panel. I made paper templates of the equipment and scored the panels with a pencil before cutting.

To mount the equipment panels in the console, angle iron with tapped holes would be ideal. Lacking that, I used wood strips surfaced with scrap chrome. This allows the panels to be mounted with either metal or wood screws.

Operating Desk

Since the operating desk (Fig. 2) must fit snugly against the main console, it shouldn't be started until the console itself is completed. To insure a good fit, make a template from cardboard or stiff paper before putting saw to wood. Plywood forms the surface of the desk and angled end supports, but I used pine for edging.

Once the desk is finished and in position, drill three holes – one on each edge near the console – through the desk and down through the supporting ledge. Add stove bolts, countersink, fill, and sand smooth.

One feature of the console that adds the "commercial look," is the Textolite plastic laminate used on the desk surface. The color was selected to match that of the main console, and provides color "coordination." Alternate materials would suffice, such as cutting up an old dinette table's Formica top. There's also the old standby of linoleum or asphalt tile.

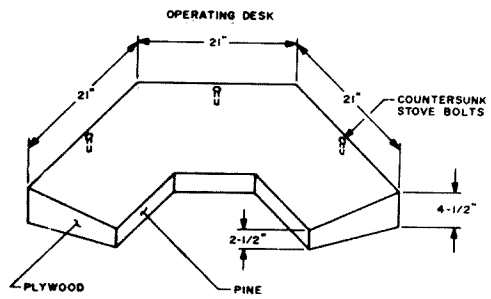


Fig. 2. The tabletop is inclined slightly for operator convenience. The design shown here was used in the author's console, but individual preferences may dictate slight differences in layout, slant, etc.

Finishing Touches

Since plywood is a thirsty material and rather grainy, take time to sand the entire unit well and then apply a good primer. Use good-quality high-gloss enamel for the finish and apply several coats. Allow for a

bit of extra paint to keep on hand for touchup later.

Panels holding the equipment are painted battleship gray, which is a standard medium color that "wears well." This contrasts with the light bluegreen used on the main console and operating desk. Gray blends with most pieces of commercial gear.

Labeling was done with "burnish-on" instant lettering dry transfers. A Datakoat protective coating will keep the letters permanently in place. The use of rub-on lettering does add quite a professional touch to the final product.

Electrical

The possibilities of designing various wiring networks for antennas, ac, audio, and accessories are virtually endless, and depend upon the station equipment to a great degree. I devoted my attention to the rf switching network—including the antenna switching system. A very complete discussion of the electrical aspects of console design was in 73 January 1969, and since W6GDP detailed it well, there is little need to cover it again.

One point might be covered, however: the use of commercial coaxial antenna switches provides efficiency and convenience over the alternate method of manual switchboard-type patching. It's one of the main selling points of any console to be able to eliminate the old juggling act of manually changing antenna coax when switching bands. My antenna network includes three coaxial switches (grounded, by the way) that allow selection of several antennas or dummy load, switching in or out the antenna coupler or monitor scope, and directing the antenna to several possible transmitters or receivers.

Piece de Resistance

A flexible microphone boom was added to the console (a "Flexo Mikester") and thus clears the operating desk of one more piece of gear. Audio cable is run to the transceiver through the rear, and since the TR3 has side-mounted jacks for phones and key, these were disabled and bypassed to standard jacks mounted on the console panel. A push-to-talk switch is likewise mounted outboard of the transceiver.

After a shakedown period, the cables and associated wiring inside the console should be secured with cable clamps. Cable runs between console sections are via holes cut in the middle of the interior walls. A hefty ground bus should be installed in each section.

One last note about keeping the desk clear of accessories: remember that there's plenty of room to mount small black boxes under the desk or in the storage area behind the speaker baffles. I had a surplus audio filter that was a "must use" with the transceiver and found that it could be neatly tucked away under the operating desk with four screws. I keep headphones out of the way when not in use by hanging them under the desk on a couple of hooks.

Removal of the tabletop and triangular "gap fillers" permits easy disassembly of the station for removal and transport. Note the "trailer hitch" connection between sections at lower right.

A good coat of paste wax on the finished unit will wrap up the job. Then you can sit down and enjoy a new dimension to hamming with everything under control and at your fingertips!

AN IMPEDANCE MULTIPLIER FOR THE VOM

A voltohmmeter or similar device can be found in almost every shack. The typical VOM is inexpensive, rugged, and independent of the ac mains. However, it has a disadvantage in that it can't be used to measure voltages in relatively high-impedance circuits without some loss in accuracy. Consider the circuit in Fig. 1. A VOM is being used to measure the voltage drop across R2. A typical VOM has an input impedance of 20 kΩ/V (or less). This means that the input impedance of the VOM, in ohms, is 20,000 times the full-scale voltage.

On the 10V scale, for example, the input impedance is 200 kΩ. If R1 and R2 are relatively small, say 2 kΩ, then the effect of shunting R2 with the VOM will be small. In Fig. 1, if the applied voltage is 20V, then the VOM will read approximately 9.9V. On the other hand, if R1 and R2 are 2 MΩ, then the VOM will read approximately 2V! Clearly, one solution to the problem is to buy a VTVM with an input impedance of 22 MΩ or so. A less expensive solution is to build the impedance multiplier described in this article.

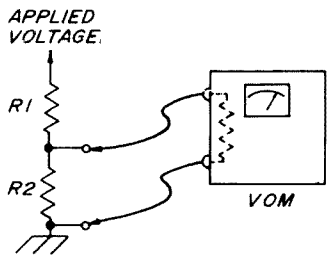

Fig. 1. Circuit under test by VOM.

The schematic of the unit, shown in Fig. 2, consists of a voltage divider which presents a 25 MΩ impedance to the voltage being measured, and an operational-amplifier unity-gain voltage follower.

The voltage follower has characteristics which make it ideal for the task at hand. Its input impedance is of the order of several hundred megohms so that it does not degrade the accuracy of the voltage divider. Its output impedance is less than an ohm and it can supply up to 5 mA (or more, depending on the amplifier used), so is virtually unaffected by the VOM. Finally, as its name implies, its output voltage is (for all practical purposes) the same as its input voltage.

For the ham who is looking at his first operational amplifier circuit, the following may be helpful.

An operational amplifier is a linear, high-gain, direct-coupled amplifier, usually provided with a differential input, but with its output referenced to ground. The usual symbol is shown in Fig. 3a. If a small voltage (a millivolt or more) is applied, the output voltage will swing to one or the other of its limits (typically ±10V). Only for voltages less than about 0.1 mV (for the ZEL-1) will the output voltage not be at one of its limits.

The polarity of the output voltage depends directly on the polarity of the

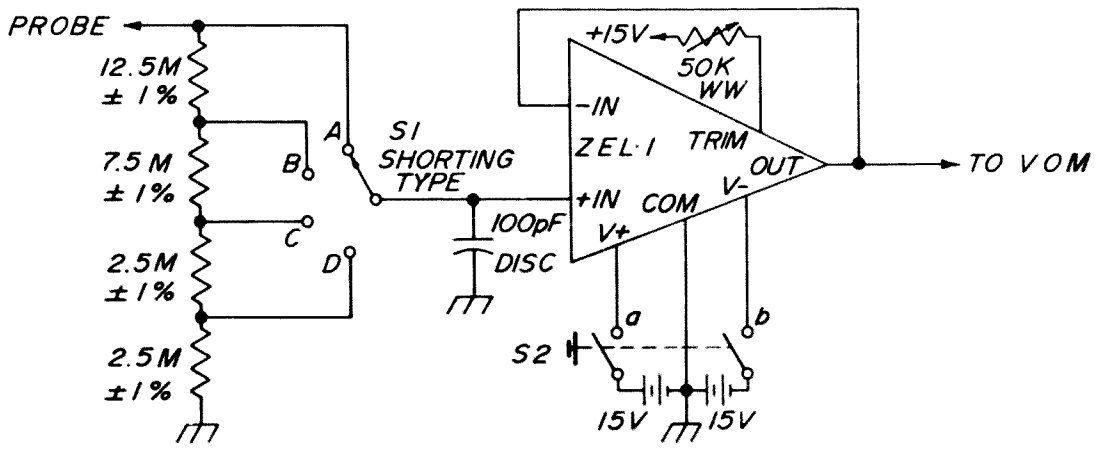

Fig. 2. Schematic diagram of the impedance multiplier.

input voltage. That is, with the positive lead of the source connected to the positive input of the amplifier, the output voltage will be positive, and vice versa. Further, instead of connecting one voltage source across both input terminals, a separate source can be connected to each input, with the second lead of each source connected to ground. In this case it is the difference of the two input voltages which appears across the amplifier input. The key to the operation of the follower is that one of these voltages is the one we wish to measure while the other is provided by the amplifier.

A simplified schematic of the voltage follower is shown in Fig. 3b. Consider what happens if, say, +5V is applied at E_{in}. If E_{out} happens to be at some value other than very nearly +5V when the input voltage is applied, then a large voltage appears across the amplifier input and the amplifier is driven hard toward one of its limits. But as the output swings past +5V, as it must because of the polarity relationships enumerated above, the polarity of the input signal is reversed, which means that E_{out} will then start to swing in the opposite direction. Because the gain of the amplifier is large and the response time short, the voltage difference across the input terminals is quickly driven to a very small value and the circuit obeys the relation:

$$E_{out} = E_{in}$$

The voltage follower is only one of a wide variety of operational amplifier circuits. The interested reader is referred to the publications listed in the bibliography.

The circuit of the voltage follower is well known and time proved. The author has constructed followers using various amplifiers in a variety of electrochemical instruments. For the ham who is starting from scratch, two amplifiers can be recommended. First is the ZEL-1, the type specified in Fig. 2, which is available for $11 from Zeltex, Inc., Concord, Calif. While the ZEL-1 is expensive, it does tend to be forgiving about having its output shorted to ground and the like. For the less cautious ham, the μA709 is available at $2 from Poly-Paks, Lynnfield, Mass. 01940. It is not nearly so forgiving. A circuit which accommodates the μA709 is shown in Fig. 4.

Other than the fixed-value components, the main difference in the circuit require-

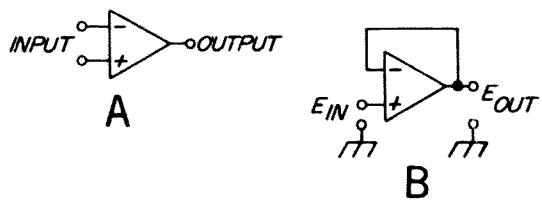

Fig. 3. The operational amplifier symbol and voltage follower circuit.

ments of the two amplifiers is the 50 kΩ trim pot which is used with the ZEL-1. The pot is used to adjust the follower output to exactly zero when the probe to the voltage divider is shorted to ground. In some applications, the absence of such a control

in the μA709 circuit would be a handicap. However, an error of only a millivolt or two is likely to result in this application. If a ZEL-1 amplifier is used, the pot may be replaced by a fixed resistor once the correct value has been experimentally determined.

to its 10V range, a full-scale range of 10, 20, 50, or 100V is provided when the range switch (S1) is in position A, B, C, or D, respectively. The unit may also be used with the VOM switched to a more sensitive range. As before, the voltage which appears at the output of the amplifier is the same

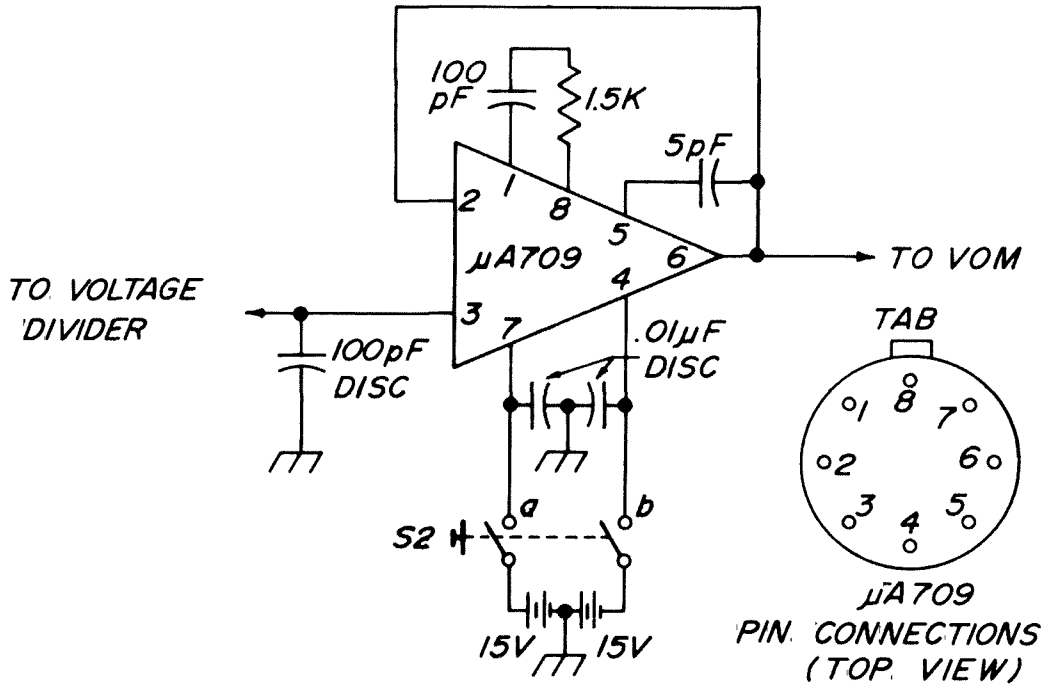

Fig. 4. Circuit modifications for μA709 amplifier.

The accuracy of readings made with the impedance multiplier in use will depend in part on the accuracy of the VOM involved and in part on the accuracy of the resistors used in the voltage divider. Since the garden-variety VOM has an accuracy of no better than ±2%, use of better than 1% tolerance resistors seems unwarranted.

A DPST switch should be provided as shown, in the interest of long battery life. Also, battery voltage should be checked frequently, since the output voltage swing capability of the amplifier depends markedly on supply voltage.

Physical layout is not at all important. The device will fit into a small minibox which can be provided with male plugs so that it can be plugged into the VOM in place of the probe leads.

Operation of the impedance multiplier is straightforward. With the VOM switched as that at the input of the amplifier, but the full-scale capability of the combination is reduced. For example, with the VOM switched to a 2V range and the voltage divider switched to position D, the voltage to be measured must be less than 20V or the VOM will go off scale.

The impedance multiplier may be used to make either dc or low frequency ac (audio) measurements. The only restriction is that not more than 10V may be applied to the input of the voltage follower.

Finally, I would like to thank Dr. Robert F. Nelson, in whose laboratory I first made the acquaintance of op-amps.

REPEATER AUDIO:

TIME OUT FOR QUALITY

Use of a cathode follower to pick audio directly from the repeater's discriminator can do wonders for an ailing amateur relay system.

by Ken Sessions, Jr. K6MVH

Ask any FM'er to describe what he thinks is the most common problem in the world of repeaters. Chances are he'll say "desensitization." If he's a repeater owner, he'll probably tell you how he fought that isolation battle for days or weeks before he finally got the repeater transmitter and receiver percolating perfectly, 600 kHz apart, in the same building, using but one antenna, and with no noticeable receiver degradation.

But the fact that the problem was overcome, as it is in almost all heavily used repeaters, removes it from the "problem" category.

All right, then, if desensitization is not the most common repeater problem, what is? In my opinion, it's *audio* – rotten, garbagey, distorted, scrapey, overclipped, overlimited, asymmetrical re-pre-de-emphasized, lousy-sounding audio. And the reason bad audio is such a problem is that it just doesn't seem serious enough to warrant the extra engineering necessary to change it.

There's plenty of chances for repeater audio to go bad. First, there's the receiver: If the low i-f is out of adjustment, certain voice frequencies will distort and loud signals will squelch out of the receiver's audio passband. There's the chance for microphonic tubes, or improper de-emphasis circuitry.

Often, a repeater builder in a hurry to get a system going will connect the speaker leads of the receiver directly to the audio input of the transmitter. In doing so, he causes the receiver audio to be processed through so many circuits that degradation could take place even if by nothing more than the process of "diminishing returns."

Every stage loses something from input to output, and the slightest bit of distortion anywhere is immediately amplified and exaggerated in all subsequent stages. Consider the stages the audio must be cycled through faithfully: The repeater user speaks, and his microphone "transduces" the sonic waves into electrical signals. These signals are generated again in the output of the transmitter's af amplifier and phase modulator. The receiver processes the audio some more from the discriminator, through audio amplifiers, through the output transformer, and finally to the speaker, where the af is again "transduced" from electrical ac to air "pressure" waves. Considering what the audio must go through from one end of the system to the other, it is no wonder that some of our repeaters sound so bad.

All this doesn't come as any great surprise to most repeater owners. They know what's wrong and how to fix it. But sometimes they listen a little too subjectively to the product of their own handiwork. To them, it may just not sound bad enough to justify circuit modifications.

If you happen to know a repeater owner whose foot happens to fit the shoe of distortion, invite him to make the "comparison" test. At the repeater site, or near it, set up a two-channel receiver capable of monitoring the repeater input and output frequencies. This receiver must have the same bandpass limiting characteristics as the repeater receiver. Then, get someone to transmit a 1 kHz tone (at the receiver's maximum deviation-acceptance level) on the repeater input frequency. Switch the receiver quickly from the repeater input to the output. If the signal sounds cleaner on the input frequency than it does on the output, it's time to reroute some of the audio at the repeater.

There are a number of places where you can pick off audio on a receiver, but none will give a signal quite as "virgin" as the discriminator. If high-fidelity audio was transmitted, you'll be able to reclaim high-fidelity audio if you get it before it gets past the discriminator.

But getting audio from the discriminator presents other problems. For one thing, the discriminator "sees" the audio before the squelch does. Which means that every time the transmitter is keyed without the presence of a quieting signal, a bothersome "squelch noise" will be transmitted. (Phone patch operation is one such case; on-site operation of the repeater transmitter is another.)

Another problem is impedance matching. The discriminator represents an extremely high impedance audio load. The transmitter audio input is apt to be quite low by comparison, particularly if input level adjustments are to be made.

Still, there is no better signal source than the discriminator, if high-quality audio is to be a criterion. And the problems aren't problems when there's a simple solution.

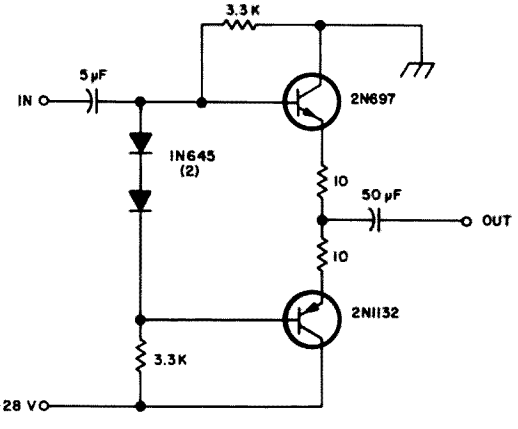

Fig. 1. This schematic from the U.S. Navy's handbook of "preferred circuits," shows an emitter follower that provides 12 dB gain. A high series resistance should be used between the discriminator and the audio input to prevent circuit loading.

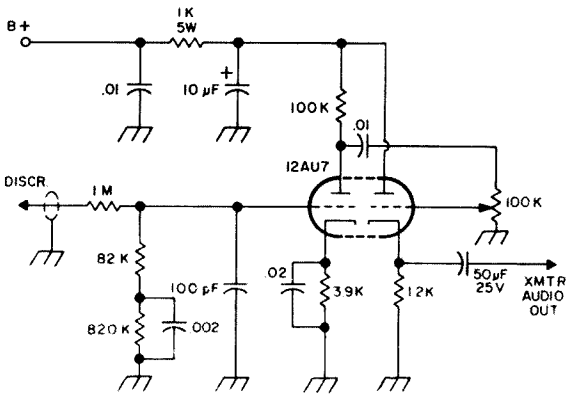

Fig. 2. This 12AU7 cathode follower is similar to the type used in commercial GE repeaters. As shown, the B+ plate supply is stabilized with a 1 kΩ resistor and filter capacitor.

Use of a cathode follower solves most of the problems. It provides excellent circuit isolation, matches a very wide range of impedances, and allows control of audio level without upsetting the receiver or transmitter audio adjustments. As a bonus, it allows completely independent local control of the repeater receiver's audio gain.

The remaining "problem" is that of discriminator "squelch" noise being transmitted when the rig is keyed without a carrier. This is solved by routing the cathode follower output to ground during all no-signal periods. The normally closed COR contacts work great for this.

The transistor equivalent of a cathode follower is the emitter follower, which will do anything a tube can do. The circuit in Fig. 1 shows an emitter-follower audio circuit that should prove ideal for repeaters with 28V dc control. (I always use −28V for repeater control because of the availability and economy of surplus 24–28V relays, and because the −28V power source can double as a transmitter bias supply.)

If no dc control voltage source is available, however, the cathode follower will probably prove more valuable. The circuit shown in Fig. 2 uses a dual triode to give one stage of amplification to the audio signal. This circuit is basically the type once used by General Electric Company in its commercially manufactured repeaters.

A well-bypassed high value series resistor, on the order of 200 kΩ, should be used between the discriminator and the cathode follower for maximum isolation and to prevent circuit "loading." In most cases the audio can be picked right off the discriminator test point, but the audio lead should be shielded to prevent pickup and processing of stray noise and audio "garbage."

The carrier-operated relay, if connected as shown in Fig. 3, does double duty by killing the receiver audio completely except when a carrier appears on the input. In this way, the repeater transmitter can be used by an on-site operator without his having to compete with squelch noise. The diode in the push-to-talk lead will prevent the COR from being triggered when the transmitter is keyed directly, and the 47K resistor provides isolation between the local mike and the audio circuit ground.

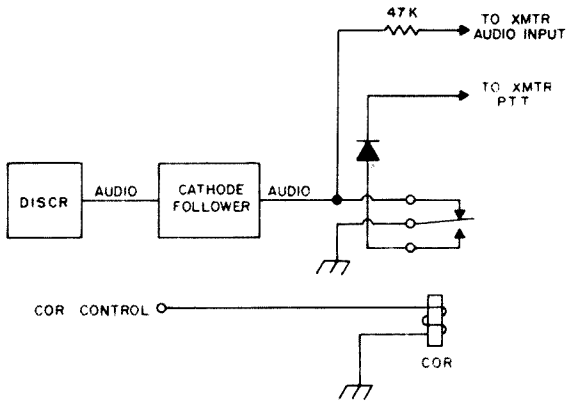

Fig. 3. The basic COR should be used to ground the receiver audio when no signals are on the input. The resistor in the audio line provides sufficient isolation so that a local mike can be used even though the audio line is grounded.

A Final Word About Quality

Repeater "listening conditions" aren't getting any better. More and more handie-talkie units are being used with repeaters, and repeater users are operating from such way-out noise sources as motorcycles, boats, skimobiles, and planes. As time goes by, repeater owners will find that effective audio will be a consideration surpassing "coverage" in importance. For after all, what good is a broad range of coverage when you can't make out the intelligence on the repeater output? But good audio *can* be built into the system. It's only a matter of taking a little extra time and putting in just a smidgen more effort.

ATV GETTING A BETTER PICTURE

Serge Miller WA6BJV
1914 Caddington Drive
San Pedro CA 90732

The amateur television hobby is spreading in many areas; it is interesting, challenging, and educational. Receiving these signals does not require a large outlay of money or a major constuction project; it does involve a certain amount of work and thought, since there is no appliance on the market ready for immediate use.

Amateur television transmission (A5) is authorized in the 420 to 450 MHz amateur band. In Southern California, AM (A3) stations operate on 432 (±0.5) MHz, ATV stations occupy the spectrum from 433 to 440 MHz and FM'ers use the frequencies between 440 and 450 MHz for repeater control and remote operation of lower frequency base stations.

As can be seen in Fig. 1, a typical ATV receiving station consists of a homebrew antenna, a transformer, a transmission line, a preamplifier, a UHF converter, and a TV set.

Antennas

A broadband directional antenna with a low swr and a relatively high gain (10 dB or more) is a must. A flat response of 8 MHz is necessary since TV signals are several megahertz (±4.5 MHz each side of carrier) wide and not every station operates on the same frequency. Yagis are not broadbanded devices unless the length of the elements are tapered, decreasing the gain. Collinears, skeleton slots, and log periodics meet the broadband and gain requirements. Groundplanes and similar omnidirectional antennas are satisfactory for general band monitoring but are susceptible to multi-

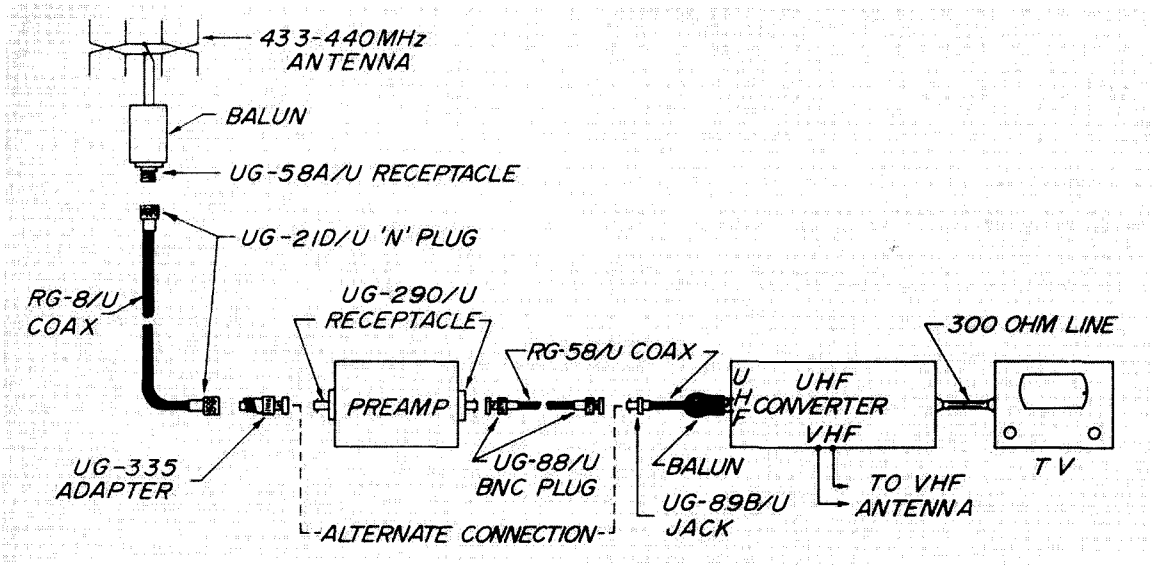

Fig. 1. Typical ATV receiving station.

path distortion and ghosts. An swr of less than 2:1 means that the antenna is matched to the transmission line and all energy is transferred efficiently. If an antenna system with a high swr is used for transmission, "ghosts" will be radiated and antenna reorientation will not solve the problem.

Most of the commercially available antennas for the ¾ meter band have turned out to be complete flops at antenna gain measuring contests. A popular brand of ¾ meter collinears has been proved totally unsatisfactory on numerous occasions due to improper match to the transmission line, incorrect resonant frequency (anywhere from 450 to 500 MHz), and short matching stubs.

A reliable workhorse in this area is the 16 element collinear shown in Fig. 2. Standing wave ratio is under 2:1 from 432 to 439 MHz, and gain is 12 dB above dipole. Check the polarization used in your area (probably vertical) and mount accordingly. Cross polarization can introduce as much as 20 dB loss, reducing the signal by two orders of magnitude!

Baluns

The antenna shown in Fig. 2 has a feedpoint impedance of 300Ω balanced. Since coaxial cable (unbalanced) is recommended, a device that will transform the impedance and convert from balanced to unbalanced must be used. Figure 3 shows two types of baluns for the ¾ meter band. The coaxial sleeve type is more difficult to

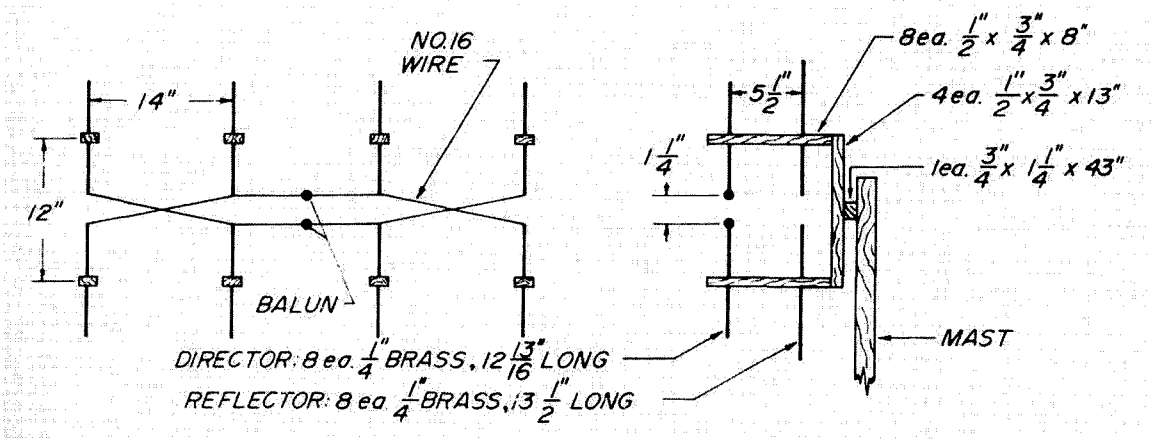

Fig. 2. 16-element collinear antenna for 432 to 440 MHz; 12 dB gain above dipole.

build, but it is more efficient and provides a better impedance match. If the antenna system is used for transmission, the coaxial line balun should definitely not be used.

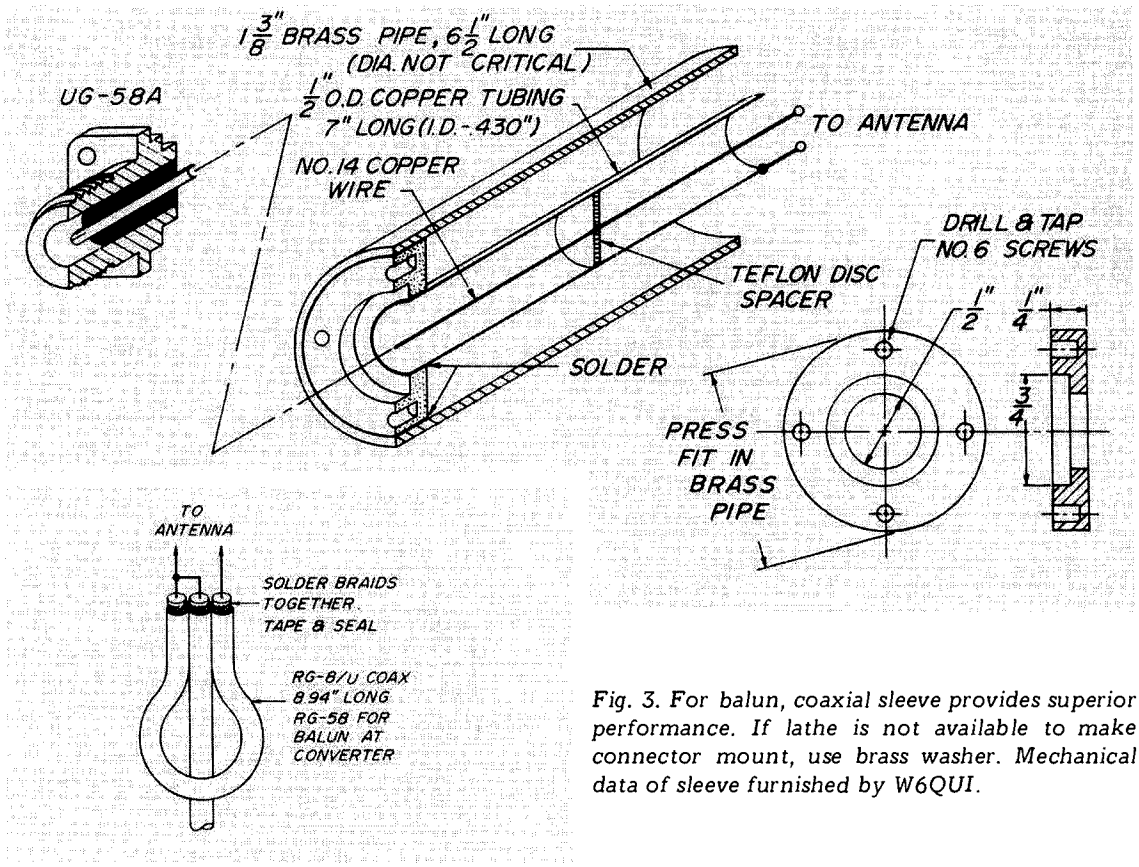
Transmission Lines

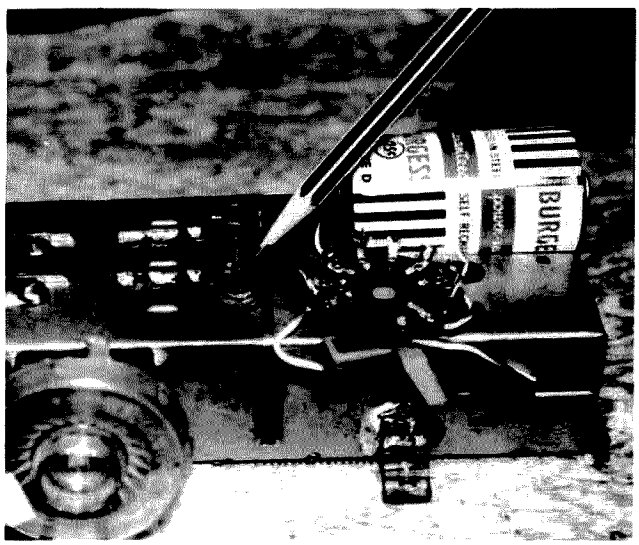
Some people blindly state that coaxial cable is not good at UHF frequencies due to high signal loss and that the only transmission line to use is parallel line.

The only time twinlead or open transmission line will perform per specification is under laboratory conditions where the line is kept away from roofs and gutters, masts and rotors, walls and windows, and the humidity is 0%; anything in the vicinity of the parallel line affects its performance. In a dry lab, tubular twin lead has 3.1 dB loss per 100 feet at 500 MHz. When the line is wet the loss jumps up to 6.8 dB. Coaxial cable can be run anywhere under vitually any weather condition. At 450 MHz new RG-8/U cable typically has 4.6 dB loss per 100 feet.

If your antenna system has 50 ft of tubular transmission line, run under ideal conditions, you will gain 1 dB of signal over coax cable and you will never see the difference on a TV set! (Yes, I know that open transmission line is better than tubular, but try to work it around a rotor or wait until several birds collide with it.)

Foamed dielectric coax cables have slightly less loss than conventional RG cables, but do not always mate properly with "N" type connectors due to an oversized center conductor. This type of cable is labeled "8/U TYPE" or "foam RG-8 type" instead of RG-8/U.





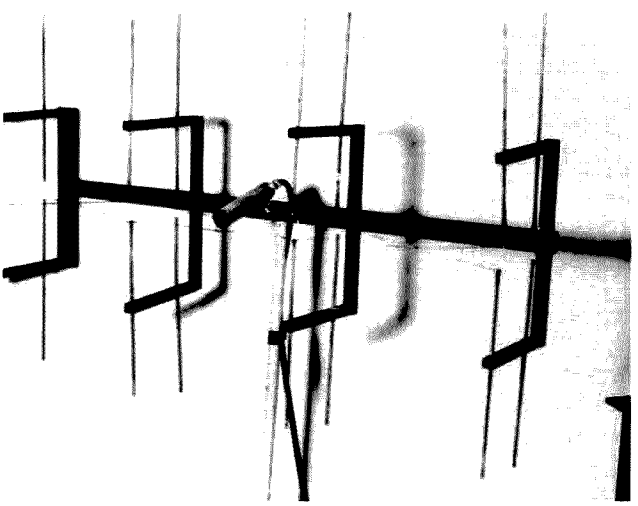


Fig. 3. For balun, coaxial sleeve provides superior performance. If lathe is not available to make connector mount, use brass washer. Mechanical data of sleeve furnished by W6QUI.

Preamplifiers

The effective radiated power of commercial UHF TV stations can reach in the megawatt category; amateur stations seldom exceed one thousand watts ERP. UHF converters have a conversion loss and noisy mixers. Even converters with amplifiers do not cure the noise problems, since the amplifier stage operates at the VHF frequencies after mixing; the converter referred to in the next section has a conversion loss of 6 dB. From the previous facts you can see that a low noise FET

Alignment screw of BTD-44 UHF converter.

16-element collinear antenna after 2 years of service.

preamplifier with at least 10 dB gain is mandatory when receiving all but local stations. Field-effect transistors (FETs) are superior to bipolar transistors due to better noise figure and less susceptibility to cross modulation.

Set Modification

The picture carrier frequency of channel 14 is at 471.25 MHz; the picture carriers in the ¾ meter band are close to 435.25 MHz, 36 MHz below the low-end limit of UHF converters. Television sets with built-in converters are not easily modified to receive ATV signals since the conversion project requires the addition of extra components within the unit, and each manufacturer has its own peculiar circuit.

A popular UHF converter in this area is the battery operated Blonder-Tongue Ultraverter, Model BTD-44. The battery lasts 6 months and keeps the cost down; and modification is simple.

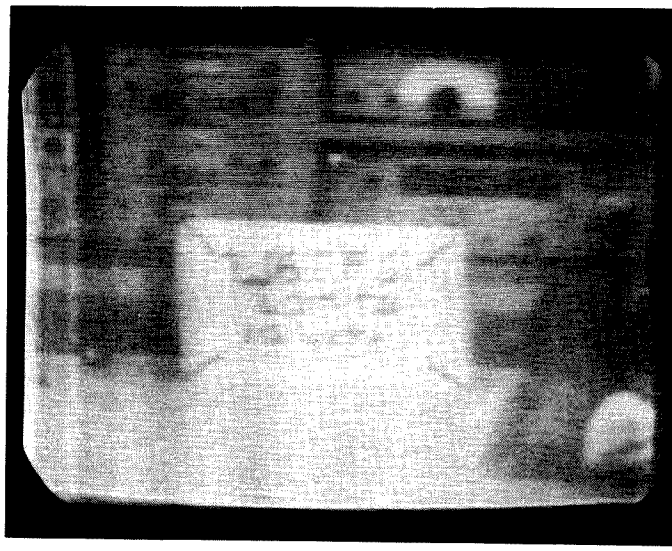
When the UHF converter is hooked up per manufacturer's instructions, proceed with the following modifications:

1) Turn TV set to channel 6 (or 5 if 6 used in your area), place converter slide switch to UHF and tune in a moderately strong station between channel 20 and 30 (28 for example).
2) Remove dial, slide converter out of case, then reinstall dial so that number of tuned channel is lined up with top of converter.
3) Rotate TV set channel selector from channel 6 to channel 3 (or 2) slowly. Every time channel selector is moved one channel, retune converter for picture of channel 28.
4) With channel selector on channel 3 (or 2), peak two alignment screws on top of converter for maximum picture. Converter is now detuned 22 MHz and dial should indicate 4 channels higher than station being received.
5) Rotate converter dial 1/8 in. counterclockwise. Turn alignment screws clockwise about 1 turn each for best picture. Repeat operations until picture of channel 28 appears at a dial reading of channel 34 (or 6

channels higher than station used as signal source). The converter is now detuned 36 MHz below indicated channel.

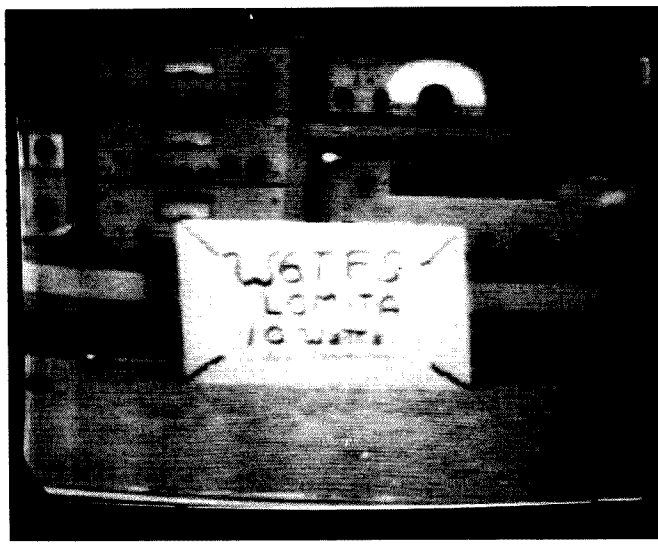
6) Turn converter dial to indicate channel 14. The converter now receives 435.25 MHz (471.25–36 = 435.25).
7) Disconnect UHF antenna from converter and connect balun made of RG-58/U cable as shown in Fig. 1 and 3 to UHF input of converter. Connect ¾ meter antenna to balun. This is necessary since broadcast UHF antennas are not efficient on ¾ meter and are horizontally polarized.
8) Modulation bars on the third harmonic of your 2 meter transmitter should be visible on TV set.
9) Arrange with a local ATV station for a signal to be transmitted in your direction. When picture is tuned in, peak the two alignment screws for best picture.
10) Reinstall converter in case and tune in channel 28. Mount dial to indicate channel 28 below marker.
11) Tune in local ATV station and mark dial under marker.

TV Set



Older TV sets can be purchased for as low as $5 from stores who do a large volume of trade-in business. Insist that set be turned on for operation before buying. Do not get involved with sets that have series filaments such as portables; they are more difficult to repair in case of failure and may have a hot chassis. The sound section should also be operational since many ATV stations are transmitting sound in conjunction with video.

When the set is used primarily for ATV operation, shrink picture horizontally and vertically a little bit to give received stations better signal evaluation.



Conclusion

With the equipment described above, I have received ATV stations from all parts of Southern California, some from the other side of mountains and others as far as 110 miles away. Now it's your turn.

THAT CONTEST CRAZE

An old tiger bares his fangs.

I've been in there pitchin' in contests for years – but each attempt to turn in a really big score has been abortive. Some unforeseen hitch – domestic, social, or business – has always come up.

This time – yes, I said *this time*, I was all set to pile up a mighty total. Lady Luck was going to be with me this weekend. I simply felt it, and what better companion to have on one's arm – especially the code arm.

Nothing had been left to chance. I had hired a spare transmitter and receiver, in case my anticipated 48 hours solo nonstop proved to be too much for my tired pile of junk. I climbed the tower and double-checked the beam. Sent the kids off to Gran and Gramp's for the coming few days. Tranquilized the dog in the hope it would sleep more than bark. I told the wife the house *had to remain quiet* – no parties, no engagements.

It was dark on Friday evening before I made it home from work.

"Supper ready?" I asked Helen.

She looked surprised. "Not quite. What, no stopover at the pub with the boys?"

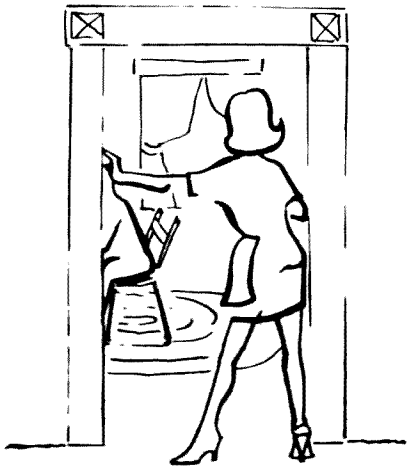
I patted her gently where she's most comfortable. "Nope, it's into bed right after I eat. Say, are those sleeping pills still in the cabinet?"

"Yes, but aren't you making a big thing of this contest?" She eyed me suspiciously.

"Maybe, Honey, but I've got to win this one. Competition's tougher each year. Lots of young bloods coming on."

"How will you pace your fading physique against a determined 20-year-old, in a two-day scrap?"

I put on a smirk. "Guile; it's an old dog for a hard road."



My wife looked skeptical. "You're an old dog, right enough, but a 30-year handicap. . ."

Sweet anticipation won't be turned bitter. This was to be *my* weekend and *my* contest. Even my horoscope said so. I was about to nudge the contest Greats. Write my name in ham history.

Deciding to recheck the rig before I turned in, I drifted into the shack. The band was wide open. And tomorrow, I'd be right in there with the best of 'em. An unfamiliar call came through the din. . .it was a pileup, calling on 8F3! Maybe I could just give a quick call before bed-time. . .

At 9:30 p.m., two and a half hours later, Helen tapped me on the shoulder.

"You're in a contest in the morning – remember? Or do you plan to work straight through?"

Piqued and smothering a testy reply, I rose and switched off the rig, letting the 8F3 die still unbagged under the pileup.

From the bathroom I called, "Honey, whereabouts in the cabinet are those pills? I'm hitting the hay."

"Left side, top shelf," she called back. "Small white box. There's a couple loose alongside."

"Ah, yes," I said, groping. I downed one without water.

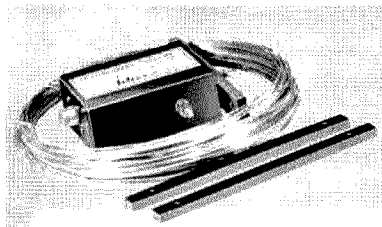
"Ugh – what a taste. Say, do you take many of these?"

Helen poked her head through the open door. "A few. Why?"

"They're foul."

"It's your taste buds. I find them a little chalky but quite mild."

Somehow Morpheus ignored my closed eyes. Why on this night above all should the gods choose to pass me up. Drowsiness would not come and the lousy taste in my mouth persisted.



"Isn't it maddening," I said to myself, but loud enough to be overheard. "Sleep is like a coquettish woman. Woo her and she withdraws her charms."

Helen made the sounds of a person whose sleep had been disturbed.

"That pill didn't do any good; and I can still taste it," I said.

Helen rolled out of bed, stumbled over to the bathroom, and I heard her rummaging in the cabinet. Finally, she appeared with a glass of water, another pill, and a small sardonic smile playing at her lips.

"What's this – another one? Is it okay to take a second one?"

"Swallow it," she ordered.

It tasted different. "What is it?" I asked.

"A sleeping tablet. That other pill was a distemper mixture for the dog."

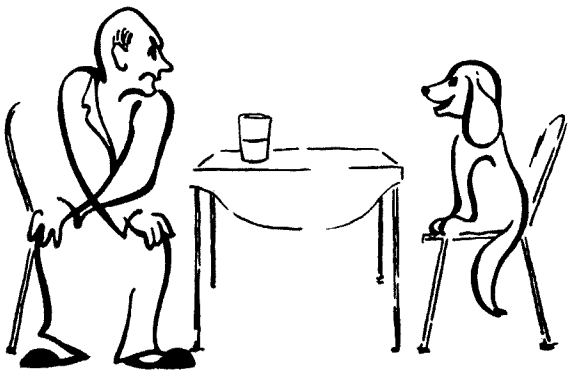
"A what?" I sat up incensed. "That bloody animal has more status around here than the kids and I have. Even his medication is mixed up with ours. Is it poisonous?"

You'll be okay," she said. "Just try and doze off."

But instead of sweet dreams in the head, I developed cramps in the midriff.

"Honey," I called again after a while. "What's the time?"

"I'll bring you the alarm clock," came Helen's voice, now slightly irritated. "You can time yourself. What's up now?"



"Can't sleep and I'm queasy. Feels like indigestion or something. "Is Jack home?" (Jack is a doctor friend of ours who lives a few houses away.)

Helen parted the drapes and peered out. "Yes, there's a light on."

I tumbled out of bed to the phone and dialed.

Dr. Jack arrived; when I told him the story, he superficially looked me over and then inspected the box of dog medicine. He began to guffaw loudly.

"This prescription contains among other things a strong deworming purgative. That's what's making you ill." For some reason, he found the whole episode quite hilarious.

When he regained his composure, Jack said, "That compound is pretty rough on the intestinal tract, but it'll probably do an old dog like you more good than harm. Just ignore the discomfort and the cramps. They'll pass." Then he was gone.

Miserably, I contemplated the ceiling above the bed. With my big moment coming up, I had to go and deworm myself. A heavy slackness was taking hold of my limbs. The pill was working.

Somewhere, very faintly at first, as if at the end of a long corridor, a telephone was ringing. Not all the time, for there seemed to be breaks, but it persisted. Slowly I became aware that someone was moving near me. Helen was pulling on a dressing gown. She reappeared a moment later and threw on the light. Dazed and stupid I slowly became more conscious under its glare.

"Wassamatter, wassatime?" Even through my sophoric, phenobarbital haze I could see urgency written all over Helen's face.

"It's 3 a.m. – the fire brigade's calling you."

"Who?"

"You – go and see."

With great effort I managed to get myself slowly upright and groped for the phone.

"Is that Mr. Shawsmith? Do you have a Real Estate office in 'Gabba Lane?" I nodded, oblivious to the fact that my caller wouldn't notice.

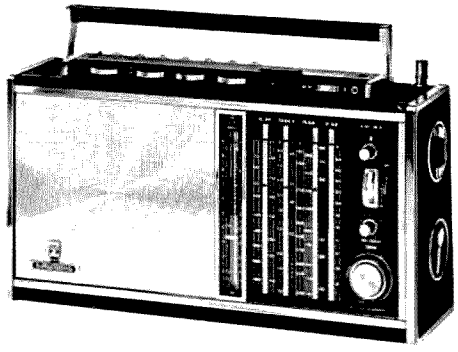
"There's a fire in the building adjoining your business. We must ask you to come immediately."

I was so doped it hardly registered. "There's a fire. . .?"

"Yes, sir; your office is in danger."

I dropped the handpiece, unable for the moment to do more.

"Honey," I said weakly, "Will you drive, I don't feel up to it?"



The glow in the sky was plainly visible.

At the conflagration the usual scene prevailed. Confusion, bedlam, and noise. We parked the car at the nearest possible spot and made down the lane.

"Helen," I shouted. "You grab the typewriters and take 'em across the road. I'll get some help with the safe." We made two or three sorties and removed most of the important papers and files before the heat became too intense. Water now began to pour through the ceiling and it was obvious nothing more could be done. We

GRUNDIG SATELLIT-AMATEUR 210

Yes, it copies Sideband and CW too!

FOR SHORTWAVE A highly sensitive receiver whose selectivity can be switched to wide or narrow for optimum results on sideband or AM. And for serious DXing, just plug in an external antenna.

FOR FM Hi-fi quality through broad bandwidth, high-power audio, and multiple speaker arrangement.

FOR SWL Easy tuning on a number of selectable bands. This receiver is sensitive enough to pull in even the weak stations without an external antenna.

stood for a while and then retraced our steps to the car only to find a young police constable, notebook in hand, pencil poised.

"This your vehicle?"

"Yes." Meekly, weakly, I answered.

"It's illegally parked."

"So are one hundred others." I swept an arm to indicate the traffic jam.

"I shall have to book you."

"It was an emergency," Helen explained. "We had just been rescuing our belongings from the blaze."

Unmoved, the cop started writing.

"You will receive a summons, but there is no need to attend court; you can simply pay the fine at. . ."

Is there anyone more infuriating than a pedantic flatfoot?

"Look," I said testily. "I don't want any instructions as regards my lawful rights. I'm more aware of them than you are. You'd do better down there helping the men." I pointed to the fire.

Helen kicked my shin. "Ssh," she whispered. "You'll finish up in the van, and that means bail money or no contest this weekend." The cop tore off the ticket and handed me a copy.

It was daylight before we slid into bed.

Hardly more than a wink went by before Helen shook me awake.

"Sixty minutes to blastoff," she said. "Thought you'd want time to snack and shower."

I lay like a slack sack. Where was my fitness of days before? Gone in the loss of a night's sleep. Dismally I contemplated the status quo. Ahead was 48 hours of bedlam and intense concentration and

already I had a pounding head. My office in ruins and a parking fine from a pin-headed cop. I cursed the fates: definitely a favorable weekend my horoscope had read.

Somehow Helen's freshness and energy provoked irritation. How could anyone be so full of bounce after such a sleepless night?

"So you're a quitter," she said. "Stop feeling sorry for yourself. A little passing 'grippe' won't kill you." My DX contest capering brings out a certain bitchiness in the old girl. It's the old love/hate complex and I still don't know after all this time if it is directed at me or to amateur radio generally. Anyway, how can a man come to terms with a woman who roots for her OM to win and at the same time disapproves of what he's doing. There's female ambivalence for you.

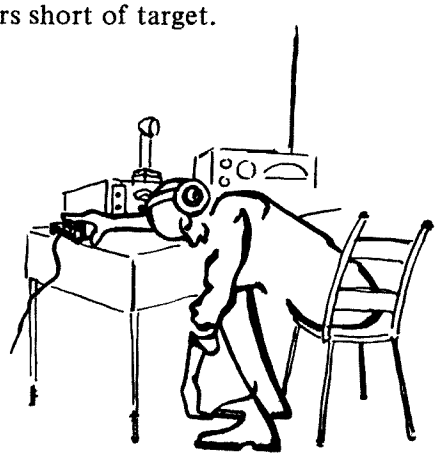
With a single movement she swept the covers off the bed.

"Come on," she urged. "Take a shower."

I fronted the bathroom mirror and recoiled. Helen's face appeared behind mine. "Hm, now you re vertical you do look rather ghastly. Guess you could use a little health and strength. "How about a prayer to St. Ionos. Isn't he your. . .?"

"Wrong saint," I said. "His portfolio is DX communication."

Then suddenly I remembered. "Say, Honey, there were a couple of pep pills in an old brown envelope. Are they still. . ."



"Al, if you take *just one* of those, you can have the house to yourself for the weekend. Fools never learn."

I dragged my tired torso off to the shack and switched on the rig. As the receiver came to life a sheaf of contest forms was shoved under my nose.

"Sign these before you get under way. Last time it was a case of 'love's labor lost'; you forgot to add your signature and were disqualified."

Again I obediently did as I was bid.

Only to a contest competitor is the cacaphony of CW actually music. However, as time wears on this sweetness turns to a painful drumming in the head. The ears become more and more sensitive by the hour, until too much of a good thing turns to sheer torture. So the race dragged on. The halfway mark came and went and the pace more difficult to sustain. It was supper time on the second evening that my wife found me, like a warrior, down but still clutching the flag, sprawled asleep at the rig. Phones on head and hand on key but beaten by fatigue and age. Twelve hours short of target.

I was hauled to a divan, divested of my slippers. As Helen threw a blanket over my somnolent form, she claims I mumbled a short philosophic comment, aimed as a barb at that Yankee poet who gave us the line, "I am master of my fate." Bah! we're just flimsy straws in the windy turbulence of existence.

Epilog

One day some months later I arrived home to find Helen jumping up and down excitedly and waving a large envelope.

"Al, I knew what this was so I opened it. Couldn't wait; hope you don't mind. It's your contest award."

I read. "VK4SS OCEANIA CONTEST WINNER. Place in Top Ten W.W. No 7." "But, hey, I never sent in a log for this."

"But I did."

"You mean you wrote out my whole log. But I didn't finish the course – remember.'"

"How could we forget; you were so piqued you went QRT for a month, but I heard on the grapevine that the bands were put out by a bad solar storm several hours before the big scrap ended; so I decided you had a chance after all."

What do you say to a wife who's so smart it hurts?

LOG PERIODIC

ANTENNA DESIGNS FOR UHF/VHF

William L. Nagle W3DUQ
RD-1 Box 188A
Honeybrook PA 19344

The log periodic antenna was originally designed and proved at the University of Illinois in 1955. Since then, the military has been making extensive use of this tremendously versatile antenna concept. Until recently, few in the amateur fraternity have known about the log periodic principle.

Through the use of computer-aided design, I have developed three such antennas for use in the amateur bands. The dimensions for the three are given in Table I. All three antennas exhibit a forward gain of 13.5 dB with a front-to-back ratio of better than 15 dB over the specified frequency range. The swr is better than 1.8:1 over the specified frequencies.

The first antenna will cover the range of 21 to 55 MHz; the second antenna will cover 50 to 150 MHz; and the third covers 140 to 450 MHz. These antennas are designed with a 5% frequency overshoot at the low end and a 45% overshoot at the high-frequency end to maintain logarithmic response over the complete frequency range specified. In log periodic antenna operation, approximately four elements are active at any one specific frequency, thus the necessity for the low and high frequency extensions. All three antennas are

Table I. Spacing and Dimensions for Log Periodic VHF Antennas.

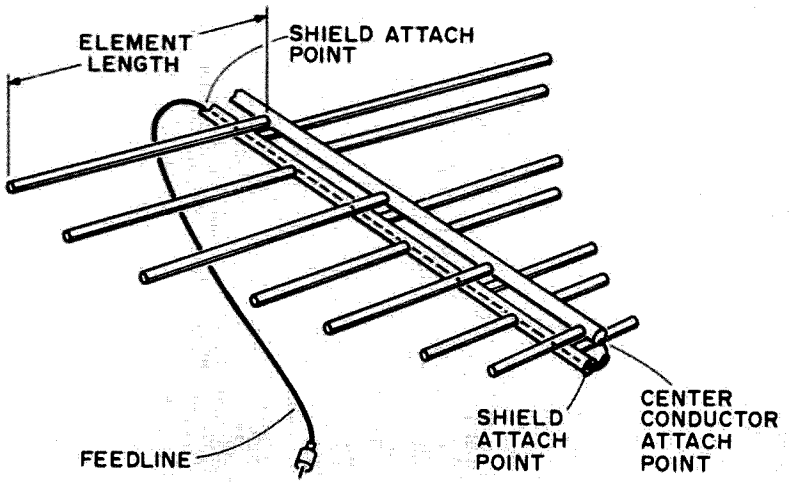

Fig. 1. Typical log periodic antenna. Note that the bottom is fed from the coax shield while the top boom is fed from the center conductor.

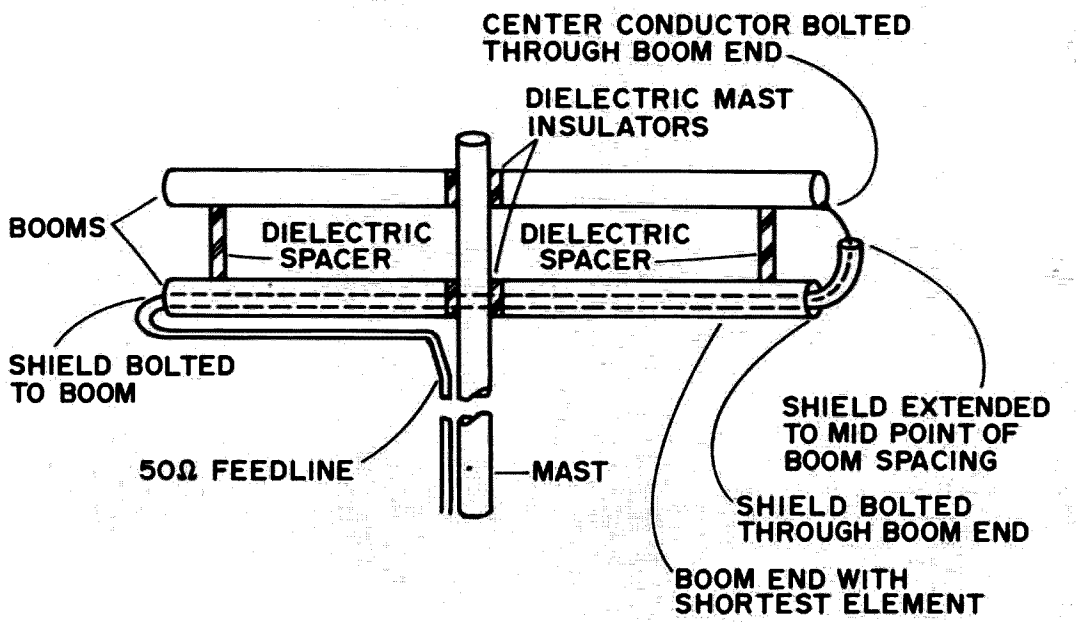
designed for a feedline impedance of 50Ω for use with coax such as RG-8/U. All of the antennas are design-rated for 1 kW, 100% modulated. The alpha, or logarithmic element taper is 28 degrees for all three antennas.

Construction

Construction is straightforward, and you can use your own ingenuity as far as fastening the elements to the boom, and also the dielectric spacer configurations. I used heliarc welding for securing the elements, and fiber glass for the dielectric.

Element lengths for the highest frequency antenna were calculated for the elements to be inserted completely through the boom, flush with the far wall. The two lower frequency antennas have element lengths calculated to butt flush against the element side of the boom. If the elements are to be inserted through the boom on these other two (21–55, 50–150 MHz), add the boom diameter to each element



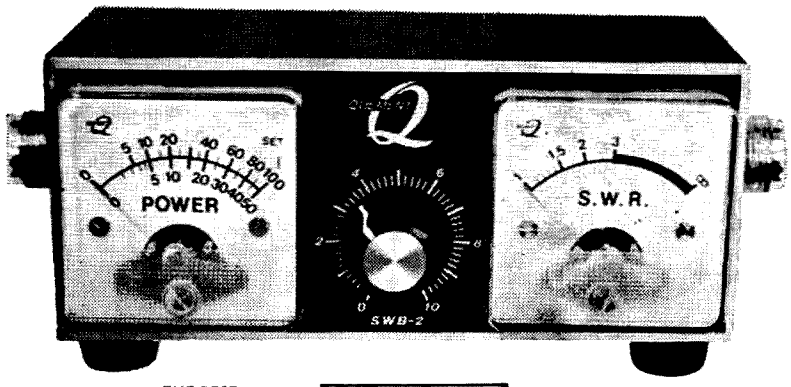


Fig. 2. Feeding the log periodic is relatively simple. Just remove the outer plastic jacket from feedline for the entire length of the boom, so that the coax shield is permitted to short itself inside the boom as well as the solid electrical connections at each end of the boom.

QUEMENT ELECTRONICS

1000 SOUTH BASCOM AVENUE SAN JOSE, CALIFORNIA 95128

"Northern California's Most Complete Ham Store"

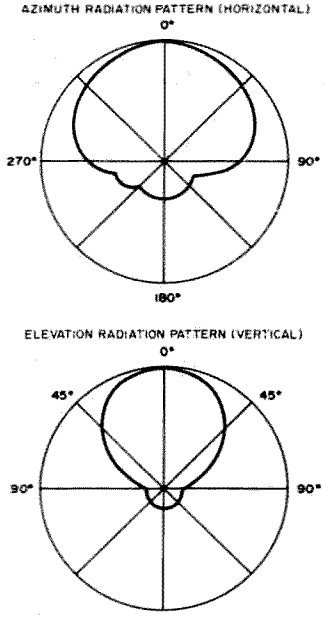

Fig. 3. Typical log periodic antenna patterns.

length shown before cutting the elements.

Two booms must be constructed for each antenna as shown in the isometric view of Fig. 1. Also remember, in supporting a log periodic antenna from a metal mast, the two booms must have a dielectric spacing from the mast of at least twice the boom-to-boom spacing; otherwise you will introduce discontinuities into the feed system.

Feedline insertion and connection are shown in Fig. 1.

Notes

Any change in the listed boom diameters will necessitate a change in the boom-to-boom spacing in order to maintain the feed impedance at 50Ω.

The location of the support mast is not critical; ideally, it should be at the array's center of gravity.

The antennas may be oriented either horizontally or vertically, depending on the type of polarization desired. The horizontal beamwidth of a typical log periodic antenna is approximately 60 degrees, while the vertical beamwidth is on the order of 100 degrees. These are the −3 dB points shown in Fig. 3.

. . . W3DUQ ■

HAM RADIO CHESS

Part I:

One of the enchantments of radio is its flexibility of application. Radio usage need not be restricted to traffic handling, ragchewing, and DX-chasing. An increasing number of amateurs are discovering the potential of amateur radio for the play of various strategic games, such as chess, checkers, and – with some adaptation – even Scrabble.

Chess is perhaps the most popular entry in the radio games category because chess by radio involves no modification to the basic rules of play and there is practically no possibility for cheating.

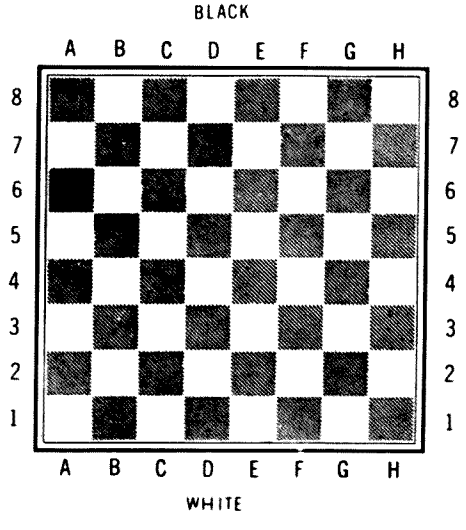
Radio chess is played almost exactly the same as the game in which both participants sit opposite each other at a board. The only difference is that each player has a board, and each moves his opponent's piece as directed by the opponent himself.

If you're a chessplayer, you know already that each chess piece has its own identifying name, and no other piece on that "team" bears the same nomenclature. Likewise, each square of a chessboard bears a name. Thus, a player can move his piece to the square of his choice, and then announce the move on the radio to his opponent. The opponent, in turn, makes the move as directed on his own board, then responds by making his own move and announcing it.

Part I: HAM RADIO CHESS USING ALGEBRAIC NOTATION

by Kayla Bloom W1EMV

Part II: HAM RADIO CHESS USING THE DESCRIPTIVE NOTATION



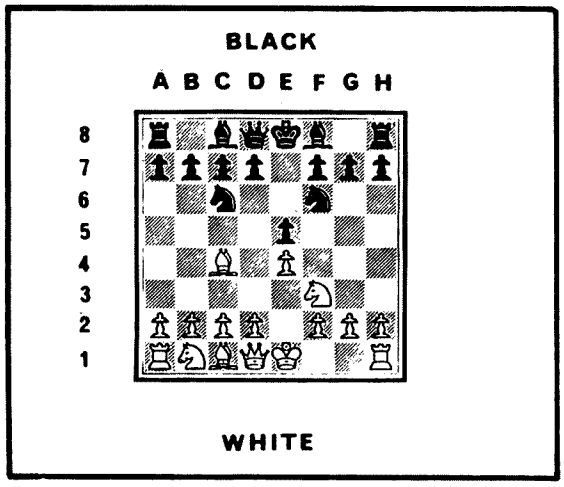
Denys G. Fredrickson WØBMW
3923 East Funston
Wichita KA 67218

Chess by radio is an ideal pastime. It doesn't tie up spectrum or airtime because the only time necessary per transmission is the time it takes to call out a specific move and get a verification from the opponent. While an amateur radio chess game may go on for several hours, there may be less than 10 minutes of accumulated transmitting time.

Most serious chessplayers are already familiar with "descriptive notation," the means by which chess moves in tournament play are recorded for later analysis and replay. Descriptive notation is the system by which each square of the board is identified according to the original piece commanding that square. While this system is easily adaptable to radio play, it is often confusing to those who are unfamiliar with chess terminology.

It also suffers the disadvantage that the squares are numbered differently for White than they are for Black; thus, when Black announces his move, White must remember not to put Black's man on his own square of the same name.

For these reasons, the matrix system (algebraic notation) is in more common general use by amateurs. With algebraic notation, the board is identified by ranks (horizontal rows) and files (vertical rows). The ranks are numbered 1 to 8 from bottom to top (from White's side); the files are identified by the letters A through H from left to right (White's side). This



arrangement yields a matrix that pinpoints each square with a letter/number sequence.

Here's how the moves would sound in a typical opening of an amateur radio game:

1. White: "Pawn to E4."
   Black: "Pawn to E4, Roger; and Pawn to E5."
2. White: "Pawn to E5, Roger; and Knight to F3."
   Black: "Knight to F3, Roger; and Knight to C6."
3. White: "Knight to C6, Roger; and Bishop to C4."
   Black: "Bishop to C4, Roger; and Knight to F6."
4. White: "Knight to F6, Roger; and. . ."

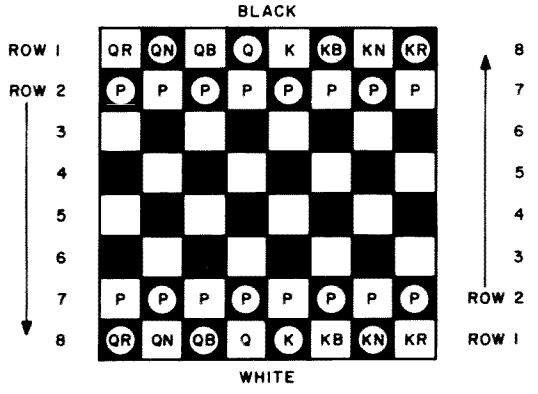
The diagram below shows the positions of the pieces after these three initial moves. (The opening, incidentally, is called "Two Knight's Defense.")

. . . W1EMV ■

Part II:

Are you slightly bored with the general QSO? Is it so dry your lips crack and your ears become dusty? . . ."You're coming in here Q-5 by 9 plus, armchair copy. I'm running a Queenie 5, a swing-a-ling multi-element swizzle stick and the modulator gets excited by the exciter when the oscillator is in oscillation. You have a bodacious signal in here. Before I run, what's my report and your handle again? I couldn't copy." . . .A couple of these and you throw the switch.

If you would like to spend one of the most enjoyable and relaxing 45 minutes you have ever spent, then pull up a chessboard and I'll introduce you to the rapidly growing game of "chess by amateur radio." Worldwide chess at your grubby little fingertips. If you know how the chessmen move, you're qualified and eligible to play chess by amateur radio.



By referring to Fig. 1, you can see that the King row is number one, pawn row is number two, the next row is number three and so on across the board to eight.

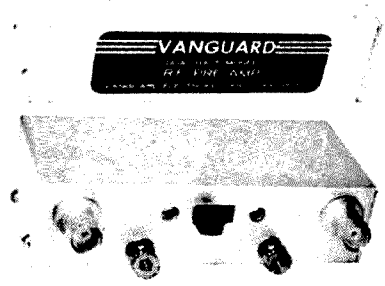
Going from right to left each file is designated as follows: King-Rook file, King-Knight file, King-Bishop file, King file, Queen file, Queen-Bishop file, Queen-Knight file and Queen-Rook file. This is all that's required to properly position a piece anywhere on the board.

The important thing to remember is to accurately call out the piece being moved and to where it is positioned. If the piece to be moved is on the King side always preface the piece by saying "King" first. As an example: If the King-Knight were to be moved, one would say: "King-Knight to King-Bishop three" or King-Pawn to King four," or: "Queen-Bishop to King-Knight five."

If you don't know what Knight it is (or day), you will have to set up another

schedule... I mean if you are confused about what knight you are talking about, then state that you are moving it from a particular position to another. Such as: "Knight at Queen-Bishop four to King five."

When there is only one pawn that can capture another piece, you can shorten it by simply saying "pawn takes pawn" or whatever. As you get into the game, numerous shortcuts will be evident. It is also advisable to make a note of each move so if an error should develop you will know how to back up or correct it. The note is a simple "KN-KB3" which reads King-Knight to King-Bishop three. Keep your moves and your opponent's moves listed opposite each other and numbered for easy reference.



I had an amateur television station in operation for the sole purpose of playing chess by TV, but have so far been unable to get anyone else interested in ham TV. I will build another TV station if someone else is interested.

Most of the chess players have been getting together above 14.3 MHz and on 7.250 MHz in the evenings and on Saturday and Sunday afternoons.

If you don't enjoy the time spent playing a game of chess, I will head for the castle on my knight and become a pawn in the court of the King and Queen with the blessing of the Bishop and that's what you call a stalemate. "Try it for kicks"...it's better than "dope." Or maybe it should read: "Dopes should try it for kicks."

DUAL GATE MOSFET
PRE-AMPS

to 175 MHz. $21.95 ppd.
to 300 MHz. $25.95 ppd.

NEW FOR 1970!
The above models now have rf gain control.

For 300 to 470 MHz
See Model 202 in our catalog.

- Available from 5 MHz. to 450 MHz. Bandwidth is approximately 3% of frequency.
- Voltage gain 30 to 40 DB depending on frequency.
- Two Dual Gate MOSFET amplifier stages with each having a tuned input and tuned output. Each Dual Gate MOSFET is actually an integrated cascode circuit thus giving you 2 cascode circuits equivalent to 4 triodes.
- Exceptionally low noise (2.5 DB at 175MHz.), greatly reduced cross modulation and 10 times the dynamic range (signal handling capability) of the best bi-polar transistors. Also superior to preamps using junction FETs and Single Gate MOSFETs.
- Internal connections for high impedance AGC or manual gain control if needed.
- Type BNC input and output receptacles for minimum loss at UHF. Standard impedance is 50-75 ohms.
- Carefully tuned at our laboratory with sweep generator and oscilloscope for the best bandpass characteristic.
- Full wave UHF diodes protect input transistor.
- Operates on 6 to 16 volts DC, 5 to 15 Ma.

New York City and State residents add local sales tax.

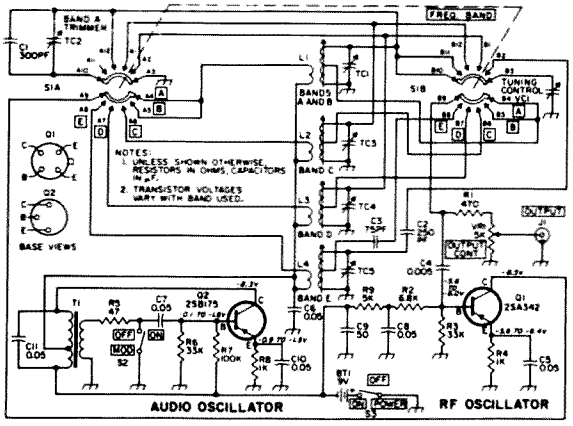
Knight Kit KG-696 RF Generator Kit Review

Elliott Kanter W9KXJ
3242 W Hollywood Ave
Chicago IL 60645

We hams pride ourselves in being equipped for just about any emergency that comes up; but for those times while mountain-topping or operating mobile, when we need a source of rf, we are prone to make do with something less than optimum. I know that I had always wanted a good rf signal generator, but I didn't want to be tied to ac power lines. I did something about my wish and latched on to Allied's KG-696 battery-operated rf generator covering from 400 kHz through 30 MHz.

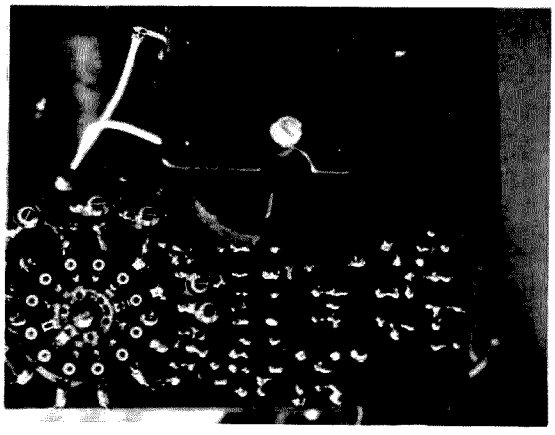


The Knight-Kit KG-696 rf generator showing molded cable assembly.

For those of you who follow changes, the Knight-Kit line has been shifted to Japan and the oriental influence is evident in this little gem. The generator consists of two transistors, a PC board, and a handful of quality components which together make up an interesting package in the less-than-$20 range. The generator contains two separate circuits: an rf oscillator and an audio oscillator.

The frequency selector switch selects one of four rf coils to provide signal output on five bands. The lowest frequency range (400–550 kHz) utilizes the rf coil for the 550–160 kHz band with the addition of some capacitance across the coil to permit tuning 400–550 kHz. Each of the four rf coils features adjustable cores and trimmer capacitors for precise alignment.

The base of the rf oscillator transistor is connected through a capacitor and the band selector switch to a tap on the selected rf coil. This is done to hold transistor loading to a minimum across the coil and provide a high-Q tuned circuit. Feedback necessary for oscillation is provided by a switched secondary winding on each rf coil.



The audio transistor functions as an oscillator generating a 1 kHz signal. A switch allows selection of pure rf or rf modulated by the 1 kHz note. Construction assembly requires approximately four hours with about one additional hour for alignment. A well written and illustrated text aids the new kit builder and proves a valuable aid to the more expert construc-

Physical Size:	5 7/8 x 5 7/8 x 3 5/8 in.
Weight:	2 lb
Freq. Coverage:	Band A- 400-550 kHz
	Band B- 550-1600 Khz
	Band C- 1.6-4.5 MHz

	Band E- 12-30 MHz
RF Output::	Over 100,000 μV
Modulation:	1000 Hz
Audio:	1 kHz, adjust. intensity
Battery:	9V Eveready 216
Price:	$19.95

Schematic diagram of Knight-Kit KG-696 rf generator and specifications.

tor. The majority of the circuitry is wired to a PC board of first-rate quality, featuring a unique application for converting a conventional wafer-type rotary switch to a PC-type component.

Interior view of PC board highlighting converted switch mounted to PC board.

As the photograph illustrates, the last deck of the switch is soldered directly to the PC board. This is accomplished by first disassembling the switch and reassembling it with the bottom wafer flush against the PC board. This simple operation is secured with somewhat oversized hardware and provides a convenient method of achieving the versatility of a PC-type switch with the economy of conventional components. This technique can and probably will be adapted for use in many amateur homebrew projects. Conventional wiring techniques are used for the other connections to the switch.

At times construction became a bit "hairy," as space was at a premium, but the entire generator rapidly took on the appearance of a mechanically and electronically stable piece of ham gear with no major problems.

Battery replacement, frequently a problem with solid-state gear, is simple. The battery (9V transistor type) is held in a clip with conventional snap-on terminals. This clip is part of a bracket secured to the bottom of the case with the battery inside.

Alignment

The entire alignment procedure is based on the use of standard broadcast station frequency reference points for the range from 600 to 1600 kHz, and a ham receiver for checkpoints on the higher bands. Shunt capacitors are included in the event the core adjustment and trimmer adjustments fail to bring the unit to satisfactory alignment. A small quantity of wax is included to be melted and deposited in the cores and on trimmer screws to prevent movement once alignment is complete.

Comments

The KG-696 represents an inexpensive means of achieving a reliable source of rf and is portable and nondependent on ac power lines. It is useful for on-site adjustments as well as a reliable fixed-station performer. Its price – less than $20 – puts it in the buying range of many of our newer hams who, though never short on ideas, are often short on capital.

A VHF AM USING LOW-COST TRANSISTORS

TRANSMITTER

This report describes a broadband VHF AM transmitter that has an output power of 4W over a range of 118–136 MHz with an rf input of 5 mW. It requires no tuning in changing frequency.

Though the transmitter is not designed for amateur use, it illustrates many principles of interest to hams, and it could probably be retuned for the 2 meter band.

The transmitter operates from a 25V dc supply; the rf circuitry is designed for operation from a 12.5V supply with collector modulation and the 25V dc requirement is due to the series modulation employed. The modulator described in this report does not require a modulation transformer, yet provides upward modulation of over 90%. In cases where it is necessary to operate the entire transmitter from a 12.5V dc source, a conventional modulator utilizing a transformer could be employed.

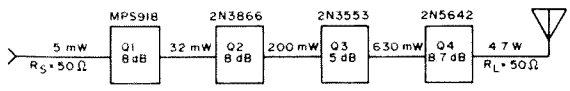

Fig 1. Block diagram of 4W VHF AM transmitter.

This note includes sections discussing the transmitter circuit and performance, design considerations, circuit layout, and testing. An additional section is included describing the modulation system used.

Circuit Description

The transmitter consists of four common-emitter amplifier stages. The block diagram is shown in Fig. 1.

The output stage (Q4) uses a Motorola 2N5642 balanced-emitter transistor (BET). These transistors were developed by Motorola to eliminate failures common in earlier rf power transistors; BETs are highly resistant to secondary breakdown due to mismatching and detuning. The 2N5642 is mounted in the stripline opposed-emitter package, which provides low-impedance strip connections and excellent isolation between the base and collector. The package is shown at the left. All terminals are electrically isolated from the stud for ease of mounting. The 2N5642 is capable of 20W output in CW or FM service, but must be downrated for AM use.

The input amplifier (Q1) is a plastic-encapsulated MPS918 transistor in the TO-92 Unibloc package. Detailed specifications on these transistors are available in the Motorola Semiconductor Data Book, or from individual data sheets.

The driver stage (Q3) uses a 2N3553 and the predriver (Q2) uses a 2N3866. These are small rf power transistors in the TO-39 package.

Amplitude modulation is applied to stages Q2, Q3, and Q4 with the supply voltage to Q3 reduced slightly with a small series resistor. A separate unmodulated dc voltage (12.5V) is applied to Q1. Two

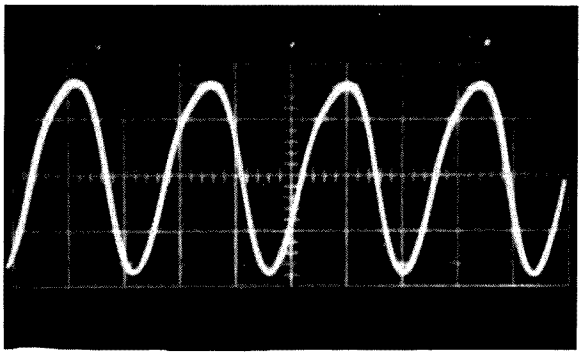

Fig. 2. Output carrier at 136 MHz (V_{CC} = 12.5V).

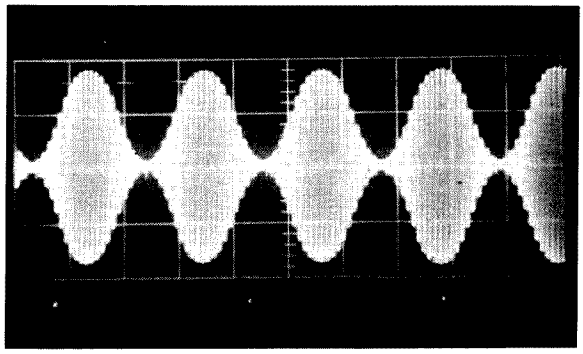

Fig. 3. Composite modulated output signal at 136 MHz (V_{CC} = 12.5V). Modulating frequency: 1 kHz.

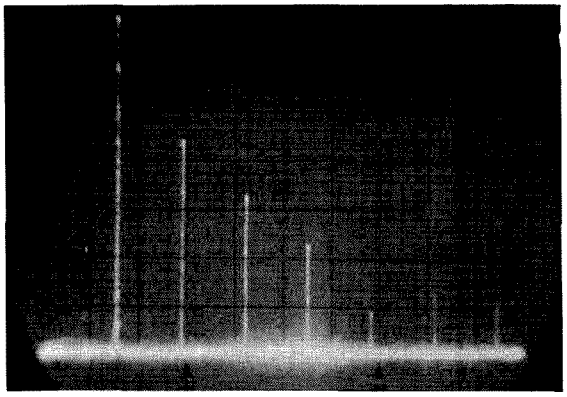

Fig. 4. Output spectrum with 136 MHz carrier (VCC = 12.5V).

diodes are used to limit the downward modulation to Q2.

Circuit Performance

Typical performance data for the transmitter is given in Table I. The driving source is a standard signal generator with a 50Ω output impedance.

The actual output waveshape at 136 MHz monitored by a sampling oscilloscope is shown without modulation in Fig. 2 and with modulation in Fig. 3.

Figure 4 shows the frequency response of the 136 MHz carrier on a spectrum analyzer. The spurious response data and output power shown were measured without an output filter.

Design Considerations

As previously discussed, the overall objective of this transmitter is a broadband modulated output. That is, the transmitter must be capable of being modulated in excess of 85% from 118 MHz to 136 MHz

	136 MHz
Power output, unmodulated (rms)	4W
Power output, modulated (rms)	5.9W
Power supply voltage (at collector of Q4)	12.5V
Power supply current (total)	530 mA
Collector current, Q4	400 mA
Power input, unmodulated (rms)	5 mW
Typical upward modulation	97%
Envelope distortion	7.9%
Harmonic Output:	
Second harmonic frequency	-24 dB
Third harmonic frequency	-35 dB
Other frequencies	-40 dB
Spurious sideband output for f_m = 1 kHz:	
Sideband amplitude at second harmonic of modulating frequency	-23 dB
Sideband amplitude at third harmonic of modulating frequency	-32 dB
Sideband amplitude at fourth harmonic of modulating frequency	-44 dB

Table I. Performance of Broadband Transmitter.

with a minimum power output of 4W; consequently, any circuitry or device used must be considered from the viewpoint of broadband modulated output rather than narrowband unmodulated output. Considering first the devices, a primary requirement here is overdrive. That is, each stage must be slightly overdriven to achieve the desired bandwidth. Since each stage is overdriven, the overall stage gain is less than that potentially possible in a normal narrowband test circuit.

Another important consideration involves the interstage networks used to transform the input admittance of one device to the required collector loading of a lower level device. Although circuit Q is important, stability and upward modula-

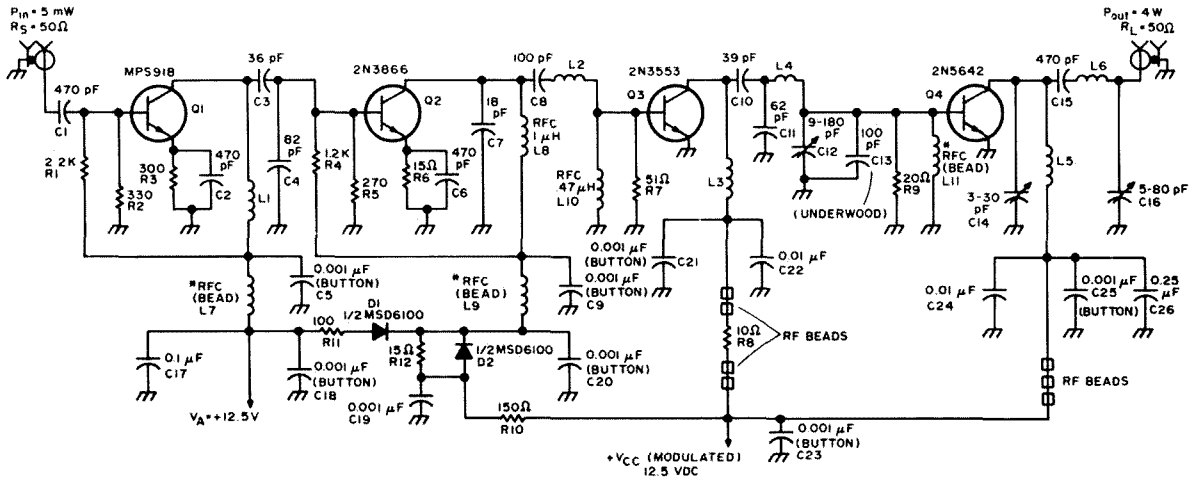

Fig. 5. Schematic diagram of broadband AM transmitter.

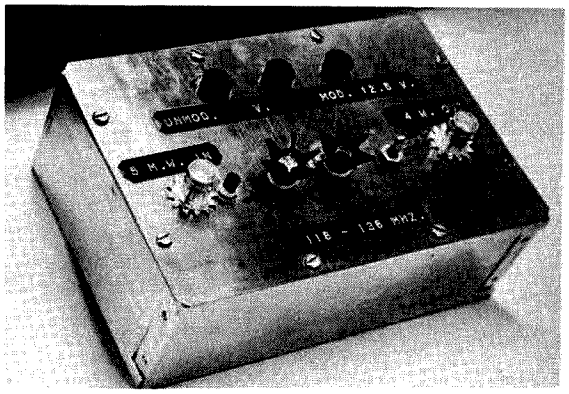

Fig. 6. Top view of transmitter.

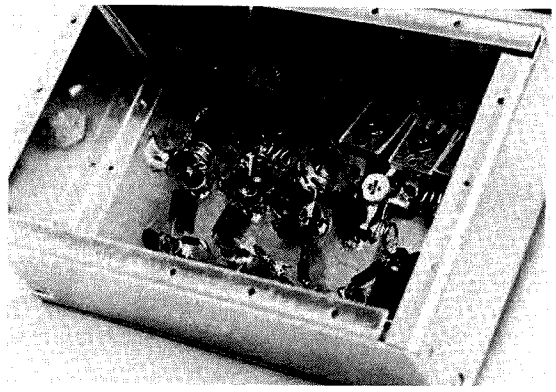

Fig. 7. Bottom view.

tion capability are equally important. One approach that can be used is to design a tentative network at mid-band (127 MHz) for a Q of 1. Incidentally, it should be pointed out that the large-signal admittance data shown on most rf power transistor data sheets is for narrowband design only. Any design involving an overdriven stage is an approximation. The circuit values can then be optimized in each network by driving the transmitter with a modulated power sweep generator.

A brief description of each stage is as follows. First, the 50Ω load is transformed to the collector of Q4 with a *pi* network. The required drive power to Q4 is approximately 630 mW for an output power level of 4.7W. The input to Q4 uses a large capacitor from the base of Q4 to ground to tune out the base lead inductance. A low-inductance capacitor is highly recommended.

The driver stage (Q3) is also collector-modulated with full upward and downward modulation. The drive level to Q3 is approximately 200 mW.

The predriver stage (Q2) is also collector modulated; however, it is primarily modulated upward. The downward modulation is limited by diodes D1 and D2. Diode D2 does not conduct during the downward modulation cycle, so Q2 is only upward modulated. When D2 is not conducting, D1 conducts and provides Q2 with a constant 12.5V supply. Both diodes are contained in one plastic-encapsulated package (MSD6100).

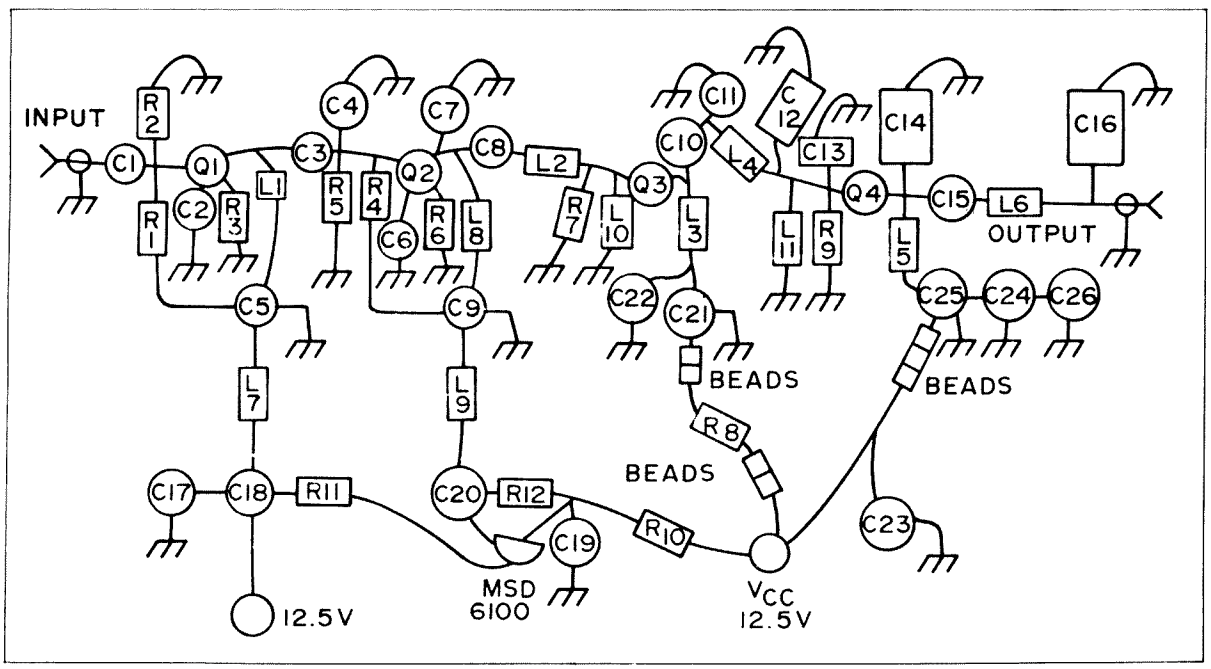

Fig. 8. Suggested component layout.

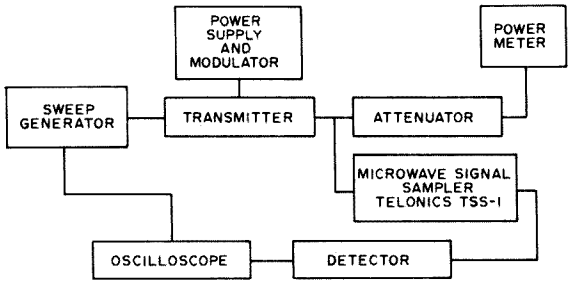

Fig. 9. Block diagram showing power sweep test.

The required input power to Q2 is 32 mW.

The input stage (Q1) is operated class A with no modulation. To insure that no instability occurs, this stage should be driven from a 50Ω source.

Circuit Layout

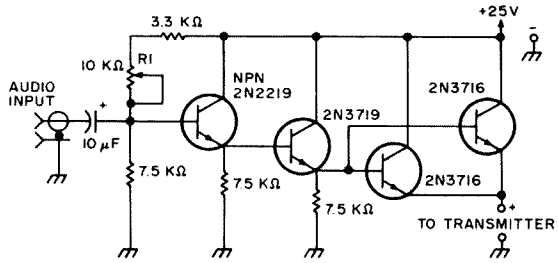
Careful attention must be paid to circuit layout. Figures 6 and 7 are top and bottom views of the transmitter, and Fig. 8 provides a layout of the components used in the transmitter.

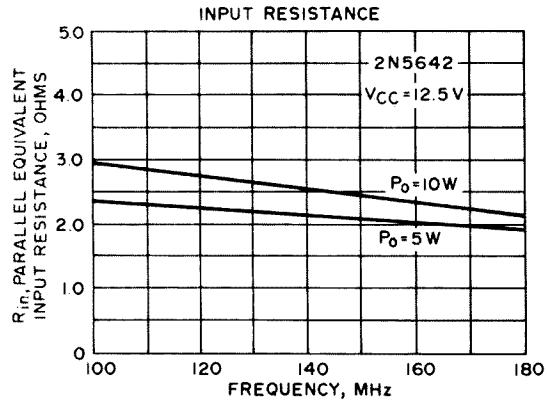
The circuit is constructed on a 6 x 3¾ in. phosphorus–bronze metal plate 1/32 in. thick. The first three stages (Q1, Q2, and Q3) use sockets. The output stage (Q4) is stud-mounted directly to the chassis.

Test Setup

An important consideration in testing as well as the component optimizing of the transmitter is the test setup. The block diagram shown in Fig. 9 shows a power sweep technique. The primary advantage of this approach is that the results of individual component changes can be observed over a wide frequency range rather than simply at an individual frequency. Consequently, two important factors important in wideband transmitters, bandwidth and instability, can be observed across the band.

A sweep generator drives the transmitter. If drive power in excess of that





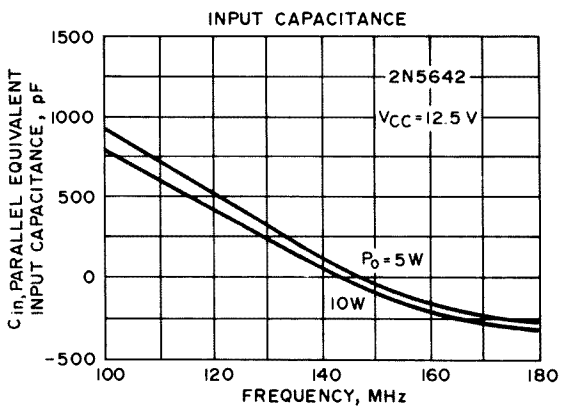


Fig. 10. Series modulator for 4W transmitter.

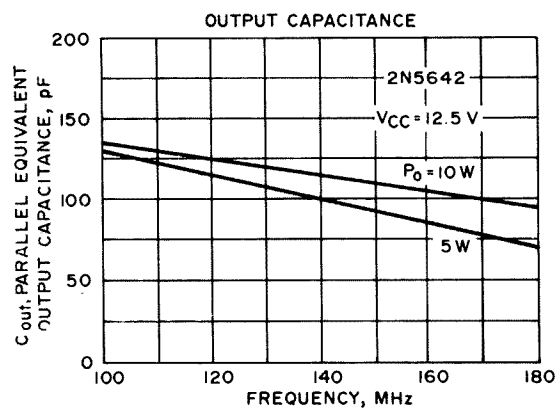

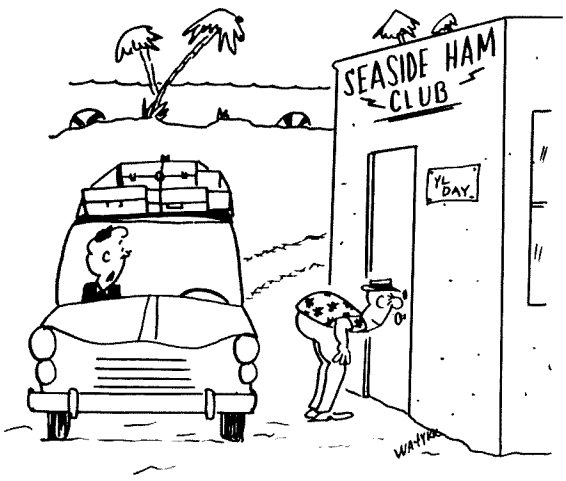

Fig. 11. Impedances of 2N5642 with 12.5V collector supply.

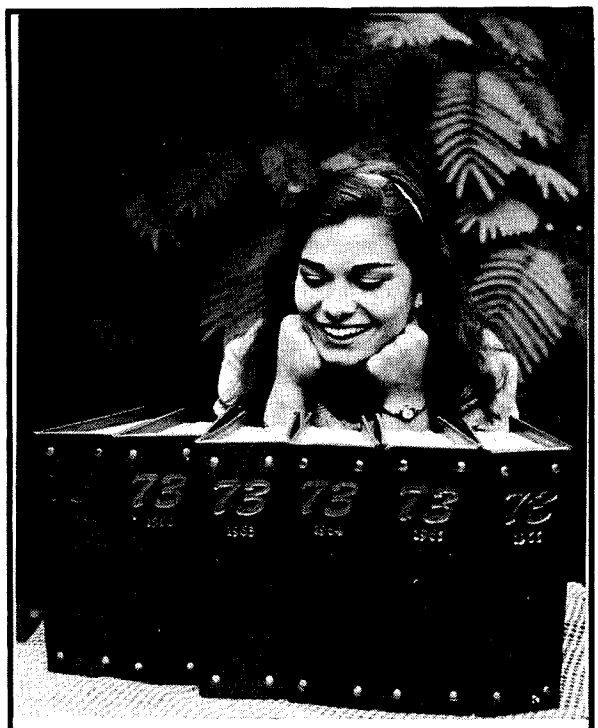

obtainable from the sweep generator is required, another transmitter can be used; that is, the sweep generator can be used to drive a transmitter, which in turn can be used to drive the circuit under test. This approach can provide high-level modulation; the transmitter supplying the drive power can also be modulated upward.

Modulation

Collector modulation usually requires a significant amount of audio power in conjunction with a large collector current. Consequently, if a transformer is used, it

"Can't you forget for two weeks out of the year that you're a ham!"

Buy 73 binders and win the love of a beautiful girl. Now only $4.00!

must be capable of operating with a large collector current circulating through its secondary winding, as well as supplying the required audio power. In addition, the transformer should furnish the required impedance-matching low distortion and low dc resistance in the secondary, since a significant dc voltage drop across the secondary winding will reduce the effective dc voltage applied to Q4.

An alternative approach is shown in Fig. 10. This method utilizes an audio power transistor instead of the transformer secondary. The collector supply to the modulator is 26V. The dc voltage to the transmitter is adjusted with R1. Although this modulator has several disadvantages such as thermal drift and distortion, it nevertheless provides a convenient method of modulating a transmitter. A more practical series modulator could include external feedback to reduce envelope distortion. The modulator shown in Fig. 10 has a harmonic distortion less than 1%. The modulator shown has been used to modulate transmitters with unmodulated carrier powers up to 35W.

Figure 11 includes three characteristic charts for the 2N5645 with 12V collector potential.

Acknowledgment

The author wishes to thank Ed Loupe for his many useful suggestions and comprehensive laboratory data generated in conjunction with the design of this transmitter.

RAISING a RHOMBIC

Me! Put up a rhombic?"

"Why not?" said Vince, "After all, you already have the toughest part of the job done."

"I do?"

"Sure. You've got three acres on top of a hill."

And this is how my rhombic began. Vince, K8LQM, our club treasurer, who is affectionately kidded about being K8L*QRM*, kept reminding me about what a shame it was for a ham to have all that land, and yet not have it covered with antennas.

I had to admit it. Ol' Vince had me thinking. I even started to have visions of DX calling me instead of vice versa. Anyway, after more encouragement from Vince, I decided I'd give it a try.

A-Frame Construction

Vince and I decided to make my rhombic 137 feet on a leg. Why this size? Simple. It would fit nicely within the property boundaries of my back yard.

Since I did not have any strategically located utility poles, trees or towers, and did not wish to spend much money to purchase any, my next question was "How do we support all that wire?"

"Easy." he replied in a tone that was just a little too nonchalant for me. Vince took pencil and paper in hand and sketched the 40 ft A-frame mast shown in Fig. 1 and the photographs. Although many articles say that the top section of the A-frame can be made of 2-by-3s, we used only 20 ft 2-by-4s. It may not have been necessary, but they were available, and we liked the added strength and rigidity it gave to the completed mast. Also, don't forget to run bolts through the bottom of each leg of the A-frames as shown in the illustration. This will keep the legs from splitting.

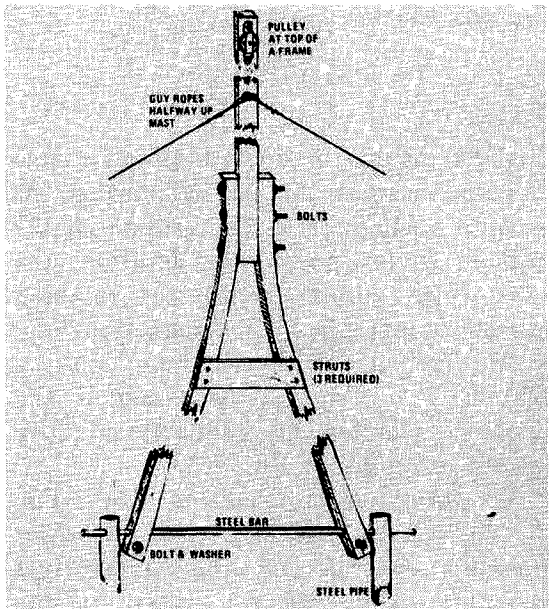

Fig. 1. A-frame construction details.

Next, I felt I'd like to be able to get these A-frames up in the air with a minimum of fuss and manpower. Again, Vince had the answer. Pivot them. This we did, as shown in the illustrations and photos. This system enables two men to "walk up" without much trouble at all. In fact I – weak ol ' pencil pusher that I am – was able to steady it all by myself while Vince tied down the guys. Even if you are not going to put up a rhombic, the A-frame

Vince (K8LQM) gets the soft job of putting the A-frames together while the author sweats over the picture-taking chores.

makes a dandy, inexpensive support for an inverted vee, VHF beam, or both.

Once the first A-frame was built, it certainly wasn't any problem to make three more of them. In fact, Vince and I were able to drill the holes and bolt them together in about 20 minutes.

When the A-frames are completed, put a couple of coats of paint on them. You can raise them up off the ground and lay them across two or three sawhorses and make the painting job a lot easier.

Vince thought it would be a good idea to paint each A-frame with a different color in a barberpole design. I painted them white. After all, they can be seen for two miles as it is, and how would it look if a high-school guidance counselor were hauled off to the happy farm for having psychedelic poles in his back yard.

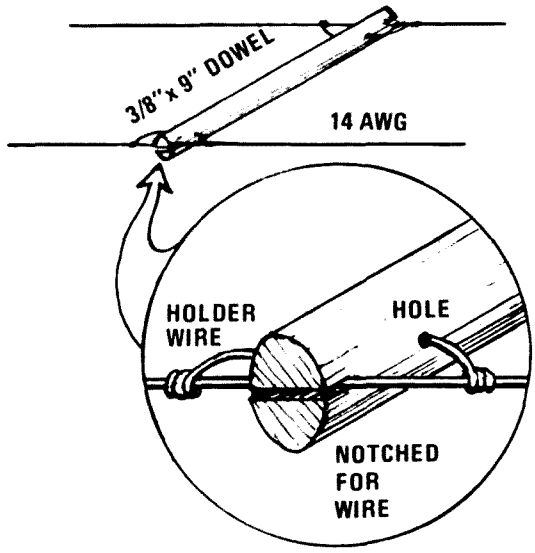
To the top of each A-frame we attached pulleys, and passed ropes through them. Finally, we attached the guy ropes. Then, when we swung them up into the air, all we had to do was fasten the guy ropes to stakes in the ground. After all the A-frames were standing, we attached an insulator and antenna wire to the pulley ropes and pulled the antenna into the air. (With this rope-and-pulley system, minor tension adjustments are very simple to make.)

Feedline Construction

If you are still with me, you are probably asking yourself, "Now that that nut has that monstrosity up, how does he feed it?" Well, I should feed it skeptical, unadventurous hams, 6 meter beams, and XYLs, but I don't. I feed it with open-wire line as shown in the illustrations. How long is it? It's just long enough to reach the transmitter – which, in my case, is about 130 ft.

I made the feedline out of 14 AWG wire and 3/8 in. dowels. Since I had plenty of it available, I used 18-gage copper-clad steel wire to attach the feedline to the spreaders as shown in the illustration. This made my ladder line so strong I could almost climb it.

Perhaps you are wondering why we made the feedline 9 inc wide. Well, the dowels came in 3 ft lengths. Not wanting to waste anything, we just cut them into 4 equal 9 in. lengths. It works fine!



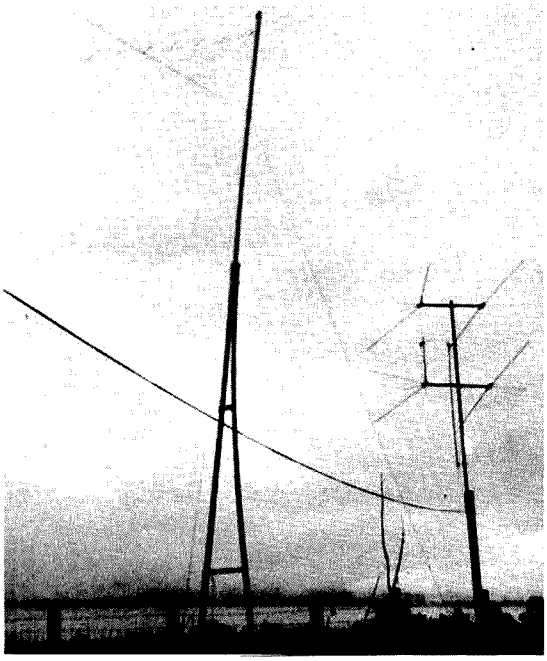


Fig. 2. Feedline construction.

This is the author's method for bringing the ladder line into the shack.

A "ladder line" open-wire feeder carries the signal from the house to the feed point on the nearest A-frame.

Especially if you have never used open wire before, you will have to figure out a method for bringing this type of feedline into the shack. I live in a frame house with the shack located in the basement. My method is the one shown in the illustrations and photos. Purists might disagree with it, but, again, it works for me.

Operation

The biggest test of all, of course, is its performance. First, though, let me give you the equipment lineup. The rigs in use at W8DYF are Hallicrafters SR-42, Heath HW-16, Drake TR-3, Johnson Matchbox, and a Knight bridge.

Using one configuration or another on the Matchbox I have been able to load the antenna on phone and CW on every band. I can't give you any gain figures, but a couple of VKs and ALs have told me I have a very good signal for 300W PEP barefoot. A WØ in Denver told me I had the needle on his S-meter shoved up as far as anyone has ever put it. Frequently, when ragchewing, fellows will break in just to tell me what a good signal I have.

Every Sunday at noon I work W8ZRI/4 in North Carolina. He usually gives me a report of 55 to 60 over. Even field day did not interrupt our schedule. We just talked right through that mountain of QRM!

One thing I am going to try is putting a terminating resistor at the far end of the antenna so that the pattern will be broader, for I do find it to be pretty sharp. For example, one night after the skip had gone out on 10 meters, I called W8DRW, a good friend of mine who lives about 18 miles south of me. He could barely hear me. However, when I tied the feeders together and fed it with the Matchbox as a random length of wire, he was comfortable copy.

I've also been using the antenna with my SR-42 and a homebrew antenna coupler on 2 meters. It seems to work fine, but seems to be pretty directional.

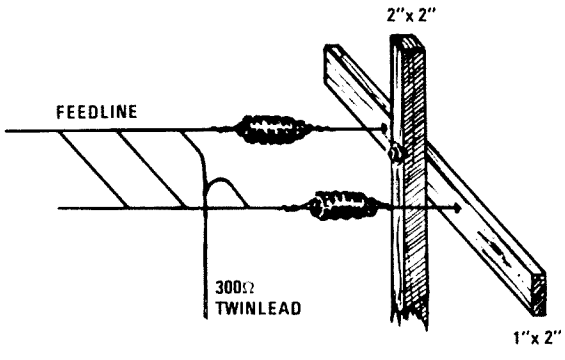

Fig. 3. Feed point details.

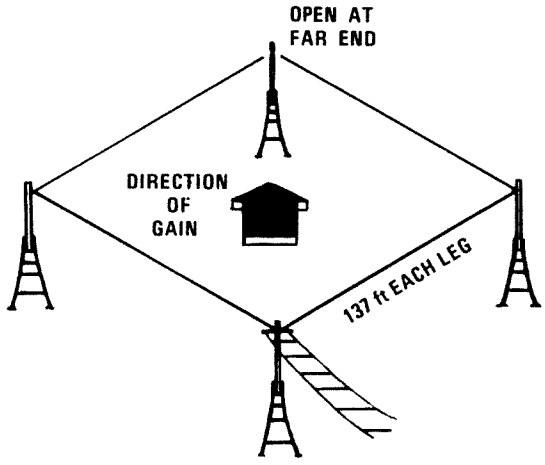

Fig. 4. Layout of raised rhombic.

All in all, I'm very pleased with the antenna. It is rather inexpensive and it permits me to operate over a wide variety of frequencies with only one antenna. Also, it's quite a conversation piece on the air. So even if you can't raise your own rhombic, I hope I've given you some ideas for a QRM killer of your own.

LEAKY LINES *(cont. from page 12)*

Why, then, are devices like can openers and electric blankets not equipped with condensers at the time of manufacture? Again, it's dat ol' debbil, money!

Despite my seeming tongue-in-cheek jocularity in this piece's opening gambit, there's a kernel of serious purposefulness in my statements. I really cannot for the life of me understand why the FCC, which has tremendous influence in all phases of the electrical and electronic manufacturing field, does not put some real teeth into some specification requirements. If any electrical device fails to meet acceptable standards with respect to interfering radiations, a temporary injunction could easily be invoked, enjoining further production until the problem is overcome. This is no more radical than the control of production in the food and drug categories, when health is imperiled as a result of substandard operations. After all, a few cents' worth of components would not impoverish these companies, or cut seriously into their profits, notwithstanding the copious crocodile tears and their howls of anguish whenever they speak of production costs. A cursory glance at the figures on corporate earnings will disclose that these industrial firms, in the main, enjoy lucrative returns on their investments. Chiseling on the price of equipment, for that is what this amounts to, is simply not justifiable on the grounds of economy. Such economy, if it is not passed on to the consumer in the form of lower costs, is really nothing, more or less, than a way to increase profits.

Why not an approval stamp, issued by FCC, attesting that the appliance is free of interfering radiations, and meets proper standards? Why not an industrial-wide code establishing such standards? We have grown used to the endorsement of the Underwriter's Lab, which reassures us as to safety from shock and fire hazard. What is so terrible about a device having to meet additional standards with respect to interference?

Remember, all it takes is an aroused and organized group. We can make our ideas heard and heeded, if only we channel our energies together. Let's make sure that not another amateur receiver is plagued unnecessarily by extraneous noise, ever again. So, man the barricades! Storm the bastile! Oust the scoundrels!

Then the only thing we will have to worry about are plain, oldfashioned 40–over–9 unmodulated carriers jerks hollering "Hello, test. Hello, hello, test!" and pests who swish their vfo's back and forth over the whole band, while the transmitters are on lock key. That's all we'll have to bother us.

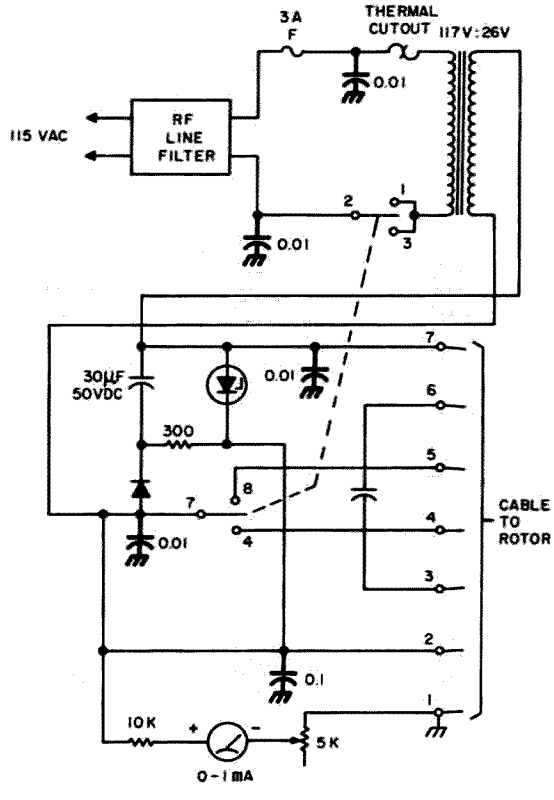
Some fun, eh, kid?

. . .K2AGZ ■

"Always be sure your obscene transmissions have redeeming social value."
Anon.

TVI from an Antenna Rotator

After several years of patient labor under tribander overload, my faithful AR-22 threw in the towel by breaking its bearings.



Since the need for upgrading was obvious, I purchased and installed a TR-44 rotator; and once more all was well in the beam spinning department.

However, during the course of a routine TVI check, a crosshatch which had not been there before, appeared on channel 6 at all power levels over 50 watts. Although located in a strong signal area, fringe area reception is simulated by using a filtered TV receiver, with indoor dipole, in the shack right under the beam. Normally, all channels are clean with 500W input on 20m.

Locating the source of TVI would sometimes try the patience of a saint, and this case was one of those times. The clue, which finally led to the detection of the culprit, was a small upscale movement, with keying, in the direction indicating meter on the TR-44 control box. This unit uses two diodes in the meter circuit – one to rectify the meter current, and a zener for meter voltage regulation. The long, multiwire cable from rotor to control box makes an excellent antenna, both to pick up the transmitter rf and to radiate the harmonics caused by diode rectification of this rf.

The rotor cable leads were bypassed to the chassis with five 0.01 μF 1 kW ceramic capacitors, as shown in the schematic. To gild the lily, a CF IF-54 rf line filter was installed in the ac line to the control box.

The meter now remained immovable with keying and the channel 6 crosshatch was gone. In this case, the interference was

Schematic of rotator with added capacitance shown in bold.

light and not of much consequence with a strong TV signal; but in a fringe area, it could have been troublesome in many respects.

Providence RI 02906

The IC mitter

This transmitter was designed with the QRP fiend in mind. It uses inexpensive ($3.80) RCA type CA3000 integrated circuits. As crystal oscillators they will work to about 10 MHz, and if you're lucky you just might be able to use them at 20 meters. This transmitter will work on 160, 80, 40, and maybe 20. This contraption will put out AM or CW at the flick of a switch.

The schematic should be self-explanatory. If you build on Vector board I would recommend using sockets. As a matter of interest, the 2N3904 is for agc. Capacitor C1 should be chosen for good agc action — try 0.05 or 0.1 μF. Transformer T1 is a swamped 10 to 5 kΩ matching transformer. The values shown for it give a fairly good match. The C2-L1 network should resonate at the crystal frequency. Tap L1 wherever you get the best match. The AM-CW function is switched by a 3-pole double-throw wafer or toggle switch. For AM work, use a 50Ω mike (or something close).

These circuits are by no means completely original. Only partly. They were lifted from RCA publication ICAN5030. Also from File 121. Both are available from RCA for the asking. These papers provide much useful data on the CA3000.

Have fun!

Stephan Goldstein ■

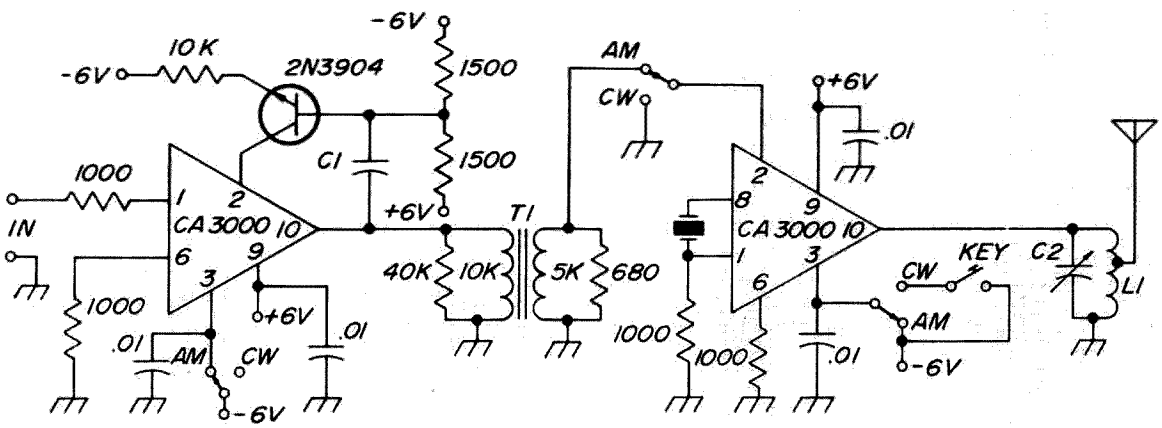

Fig. 1. See text for C1, C2, L1, T1. For CW you can also switch out the transistor if you want. Instead of keying the voltage, you could key the output. If you don't want agc, simply ground pin 2 of the first IC.

STUDY GUIDE GENERAL CLASS LICENSE

PART II

Now you see it, now you don't!

The General Class license examination covers many fine points of radio theory and practice – and many most basic points as well. Since the basics are necessary as a foundation upon which to build the fine points, we began this study course in our previous installment by accounting for voltage, current, resistance, magnetism, and the propagation of electromagnetic energy.

And since our space was, as always, limited, we did not get around to many of the basic points involved in ac circuits. That's our subject this time.

If you missed the previous installment, by all means obtain a copy before going further in this one. The two actually fuse into a single discussion, and we'll be making frequent reference to points covered before.

As always in these license study courses, we're working from the official FCC study list of "typical questions" – but we're not answering the Commission's own questions. Instead, we're expanding their range to cover a broader area, and examining that broad area in as great detail as we find necessary.

This time, the FCC questions we will cover are (numbers from the study list, as usual):

3. Define skin effect. How can this phenomenon be minimized?

33. What are the distinguishing features between series-tuned and parallel-tuned resonant circuits? How is the resonant frequency determined? Define the "Q" of a resonant circuit?

38. What is inductive reactance? Capacitive reactance? How is their value determined? How do like reactances combine in series? In parallel?

In addition, we will be winding up portions of questions 27, 35, and 36, which were begun last time around.

Because we know from our previous study what inductance, capacitance, volts, ohms, and amperes are, as well as series and parallel circuit connections, but have not yet met "reactance" or "resonant frequency," let's begin by asking "HOW DOES AC BEHAVE DIFFERENTLY FROM DC?" This will permit us to explore not only reactance and skin effect, but a more basic concept called impedance. From there, we will try to determine "What is resonance?" This discussion sets the stage for much of the later "practical work" on tuning of both receivers and transmitters. The "Q" factor is closely allied to "resonance," but is enough different that the question "What is Q" deserves its own discussion.

By the time we explore these three general questions, we should have a solid foundation in both ac and dc circuit theory, and be ready to move on to some advanced theory by next time around. Let's get started, then.

How Does AC Behave Differently From DC? We saw last time out that ac must be

measured differently from dc, because of the fact that ac is continually changing not only its intensity but its direction of current flow. We said at that time that voltage, current, and resistance were not so simply related in an ac circuit as they are with dc, as well, but we didn't dig in any deeper.

Let's do so now. Last time, we saw that resistors convert electrical energy to heat energy, that inductors impede changes in the flow of current, and that capacitors contain insulators which interrupt the steady flow of current.

All these effects are perfectly true of steady-state dc. With ac, however, there never exists a "steady state," because both the intensity and the direction of the current are always changing.

In a capacitor, for instance, a steady or dc potential will cause an accumulation of charge across the insulator or dielectric. If the potential is then increased, the charge which already exists will be of the same polarity. Since like poles repel each other, the charge already existing will tend to oppose the increase.

However, because of the "brute force" provided by the increased potential, electrons *will* move within the dielectric to establish a new state of charge and bring the capacitor's charge into balance with the applied voltage. Only after this movement has occurred will the full applied voltage exist across the insulation. The time involved is exceedingly small, but the net result is that a capacitor delays the voltage until current flow has stabilized.

If we apply ac rather than changing the voltage of applied dc, the same basic rules apply – except now, the current flow never stabilizes. It just keeps on changing, and the voltage never quite catches up to it. The net result is that the voltage cannot reach a peak value while current is flowing, and when current is at a peak of intensity no voltage exists across the capacitor.

In between these times, current will decrease from its peak as voltage increases from zero.

We express this by saying that the voltage "lags" behind the current.

Most usually, a simple statement that the voltage is lagging doesn't describe things accurately enough. We need to know just how far behind the current peak the voltage peak is located.

We could express the time in fractions of a second, but then we would also have to specify the frequency of the ac involved. To avoid this entanglement, we use the ac cycle itself as our time scale. Recall our simplified ac generator of last installment, which generated one full cycle of ac during one revolution of its shaft through 360 degrees of arc. We use this fact, and say that a full cycle of any ac sine wave occupies 360 degrees of a phase; that's our way of measuring time in ac circuits.

Since a full cycle is 360 degrees, let's arbitrarily set our zero-degree point on the instant when the current is crossing zero in a positive-going direction. The current's positive peak will then occur 1/4 cycle later, or 90 degrees. The next zero crossing will be another 1/4 cycle later, or at 180 degrees, and the negative peak will be still another 1/4 cycle after that, or at 270 degrees. At 360 degrees, we will complete the cycle and be back at the "zero" point of the next cycle.

To apply this to the voltage lag in a capacitor, let's see what happens to the voltage at these same four points in the current waveform.

When the current is at zero degrees, with the waveform crossing zero and going positive, the voltage is at its negative peak. This is the 270-degree point on the previous cycle, or 90 degrees behind the current.

When the current is at 90 degrees, at its positive peak, the voltage is just crossing zero going positive. This is the zero-degree mark of the current cycle, the same intensity which the current had 90 degrees earlier. Voltage is still 90 degrees behind current.

And, in fact, all the way through the cycle, the voltage is always 90 degrees behind the current – if a perfect capacitor is used, with no resistances anywhere in the circuit. This, of course, cannot be achieved in practice, but we can come astonishingly close.

Note that there's a very major difference here from what happened in the dc-circuit. With dc, the capacitor blocked all current flow. With ac, current flow continued right on through the capacitor, but the "lock step" relationship between current and voltage (which existed when the ac left its generator) has been disturbed, so that voltage now lags by 90 degrees.

Since we're assuming that there was no resistance anywhere in the circuit, no energy was turned into heat. However, with the current and the voltage waveforms out of step they are no longer capable of producing the same amount of power as they were before meeting the capacitor. The energy has undergone an apparent loss, but actually it's just out of time.

Because this apparent loss is due to a reaction brought about by the capacitor, we call it an effect of "reactance." Because the apparent loss is real enough to affect any circuit connected to it, we measure reactance in ohms just as we do resistance. The major difference between reactance and resistance, at this point of the game, is that resistance loses the energy permanently by turning it into heat, while reactance merely locks it up and makes it unavailable for us to use.

Going back now to the reason why voltage and current get out of step with a capacitor – the fact that the existing charge at any instant opposes any increase in charge – it shouldn't be extremely difficult to see that the more rapid the attempted increase, the more rapidly the change will occur. Similarly, the greater the capacitance involved, the more thinly spread will be the "existing charge" and the less it will be able to oppose the changes.

These two observations lead us to the point that the *greater* the frequency of the ac signal, and the *greater* the capacitance in question, the *smaller* will be the reactance..

Going in the other direction, as the frequency becomes ever lower it gets closer and closer to being dc, and since a capacitor is an open circuit for dc it must be a very high value of reactance for very low frequency ac. There's a formula for calculating reactance in ohms of any capacitor if you know its capacitance and the frequency of the ac signal involved, but we won't go into that just now. First, let's look at another form of reactance.

We have just seen that a capacitor introduces reactance into an ac circuit because its charge opposes any change in voltage across itself. We also know that an inductor opposes any change in current.

Because of this, the reactance of an inductor does not cause the voltage to lag behind the current as does that of a capacitor. Instead, with an inductor, the current lags behind the voltage.

The reasons are exactly parallel, however, to those which apply in the case of the capacitor. When the current flow is zero, there's no opposition (for a brief instant) and voltage intensity is at its peak. When current flow is at a peak, opposition is at a maximum and voltage hits zero. Just as with the capacitor, the inductor's reactance causes voltage peaks to coincide with zero-crossings, and the voltage zero-crossings to coincide with current peaks.

This means, automatically, that a 90-degree phase difference is introduced between the current and voltage waveforms by pure inductive reactance. Since it's the current which is delayed, this time the voltage is 90 degrees ahead of the current rather than 90 degrees behind.
delayed, this time the voltage is 90 degrees ahead of the current rather that 90 degrees behind.

Figure 1 illustrates both of these conditions, as well as the normal nonreactive relationship between voltage and current in a resistive ac circuit.

Current lag instead of voltage lag is not the only difference in a reactance between capacitors and inductors. They behave a bit differently with respect to inductance values and to frequency, also.

The more rapid the attempted change of current in the inductor, the more opposition is developed. Going the other way, the nearer the signal frequency gets to dc, the less effective the inductance is, since inductance has no effect at all on steady-state dc.

This means that while the reactance of a given capacitor decreases as frequency goes

up, the reactance of a given inductor goes up as frequency increases. The higher the frequency, the greater the reactance.

Similarly, the greater the inductance at any one frequency, the more the opposition. Thus the reactance increases as the inductance value climbs, while capacitive reactance decreases as capacitance is increased.

Since capacitive reactance and inductive reactance behave so differently in these three different areas, we must have some way of telling them apart in our equations and theories. The behavior is so different that they almost appear to be opposites. One causes current to lead; the other causes it to lag. One increases with frequency; the other decreases. One decreases as its corresponding unit increases; the other increases right along. This "opposite-ness" of characteristics is used to tell them apart in our symbols. We use the "+" and "-" signs of arithmetic to designate which kind of reactance we mean. If the reactance is capacitive, we tag it as "-"; if it's inductive, we call it "+."

This would indicate, and Fig. 1 would back us up on it, that we could use some of

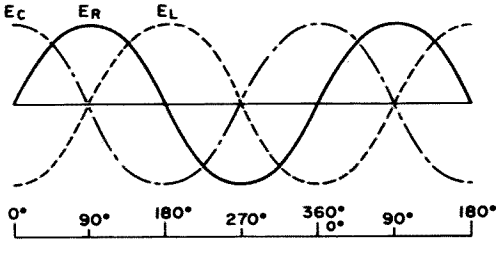

Fig. 1. Effects of capacitance, resistance, and inductance on phase relation between voltage and current are shown here. In all three cases, current phase is same as waveform E_R. Capacitance causes voltage phase to lag 90° behind voltage, which is same as causing voltage to lead current by 90°. Phase scale at bottom refers to phase of current waveform.

one kind of reactance to cancel out some of the other kind. As a matter of fact, we can do just that, and we're going to look at that process in great detail rather shortly. All we'll mention about it here, though, is that this gives us a "key" to "unlock" the power which was locked up in the ac signal by just one kind of reactance.

Now let's turn the tables just a bit, having met both kinds of reactance, and find out how to relate capacitor values in microfarads or inductances in ~~henries~~ to reactances in ohms.

It takes a bit of algebra, but nothing more complicated than Ohm's Law. Figure 2 shows the equations, in two forms. The

$$X_L = 2\pi fL$$

INDUCTIVE REACTANCE
(full formula, ohms, hertz, henries)

$$X_C = \frac{1}{2\pi fC}$$

CAPACITIVE REACTANCE
(full formula, ohms, hertz, farads)

$$X_L = 6.283fL \qquad X_C = \frac{159}{fC}$$

X	in ohms	X	in ohms
f	in megahertz	f	in kilohertz
L	in microhenrys	C	in microfarads

Fig. 2. Reactance equations. Versions at top are full basic formulas, with all quantities in "basic units." Those at bottom are practical versions. See text for details on their use.

first form of each equation is the full basic form, with all units in "standard" values such as hertz (cycles per second), farads, henrys, and ohms. The second form of each is the "practical" one for radio work, with units in more convenient form such as μF, kHz, μH, etc. The answers, however, still come out in ohms.

In case you're wondering how "pi" gets into the act in the first form of each equation, the answer gets a bit sticky. The most completely basic form of each equation is one of Maxwell's equations, which deal with rates of change and so involve concepts met in differential and integral calculus. To get from the "curl" of the electric and magnetic fields down to the "ohms" values which are of practical interest to us, it's necessary to go through

some partial differential equations. These, in turn, don't work with "degrees" or hertz, but instead with "radians," which are a different way of measuring angles that depends upon the ratio between the radius of a circle and the arc cut out of that circle by the angle involved. To convert from "radians per unit of time" into "hertz," we have to convert a measurement based on the circumference of a circle into one based on the number of revolutions. "Pi" is the factor which relates these, and that's why the reactance formulas both include "2 pi" as a factor.

"2 pi" as a factor.

In practice, of course, you don't have to worry about "pi" at all – because the magic figure "159" with the appropriate number of zeros fore or aft takes care of it, as well as doing the dirty work of converting from farads to picofarads, or from henrys to millihenrys.

The physical facts which these equations represent are those which we've already met in our introduction to reactance. A reactance in a circuit which contains no other elements will always have applied to it the maximum voltage which the source can provide. The reactive element's opposition to change – that is, to change in voltage in the case of a capacitor or to change in current in the case of an inductor – will act to limit the flow of current in the circuit to just that which is necessary to keep the circuit electrically balanced at all times.

We already know that a capacitor, for instance, offers less reactance to a high-frequency signal than to one of low frequency. The more rapid change of applied voltage brought about by the higher frequency signal requires a larger current flow to keep the circuit in balance or equilibrium. Similarly, for two capacitors of different capacitance but with the same frequency of applied ac, the larger capacitor will require more current to keep the charge at just the level which will satisfy the applied voltage.

The reactance equations simply express this relationship between voltage and current, in terms of capacitance (or inductance) and frequency.

Now that we are able to express a capacitor's or an inductor's value as "ohms of reactance" at any specific frequency, let's see how ohms of reactance combine with ohms of resistance. Cast an eye upon Fig. 3, which shows us a resistance-capacitance series circuit.

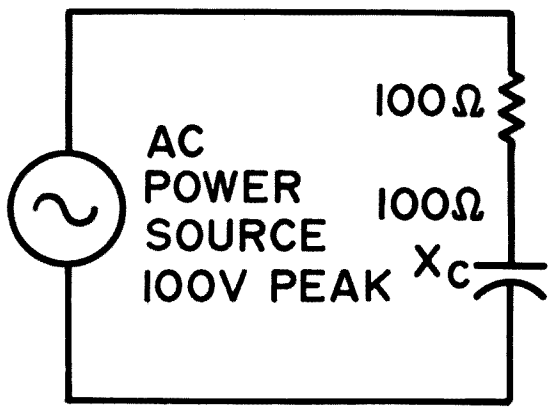

Fig. 3. Series L-C-R circuit illustrates how reactance and resistance combine. Effects of each influence action of total circuit, and result is neither purely resistive nor purely reactive. inductance behaves similarly.

In the explanation which follows, we'll assume that both the resistor and the capacitor are "perfect" or "ideal" components. That is, we'll act as if the resistor has no reactance at all, and the capacitor no resistance.

Since the circuit is a series circuit, by the definition we learned last time around, all of the circuit current must flow through each element. With dc applied, there will be no current after the initial transients die out, because the capacitor interrupts its path. But with ac, current will flow at all times, as the capacitor charge follows the applied voltage during each cycle.

Were the capacitor alone in the circuit, the voltage would be varying up to the full peak value provided by the power source, and the current would be that value defined by the capacitive reactance formula; with a 100-ohm reactance, it would be 1/100 the voltage value. In addition, the current waveform and the voltage wave-

form would be 90 degrees out of phase with each other.

Were the resistor alone in the circuit, the voltage would also be varying up to the full peak value provided by the power source, and the current would be that value defined by Ohm's Law; with a 100-ohm resistance, it would be 1/100 of the voltage value just as for the reactance we just looked at. In the resistor, however, current and voltage waveforms would be *in* phase with each other.

What happens when both are in the circuit? We know that any current which flows through one must flow through the other. Let's assume that our power source is putting out 100 volts peak (200 volts peak to peak, or 70.7 volts rms) and that both the resistance and the reactance have values of 100 ohms each (at 0 and –90 degree angles, respectively). That would indicate that 1 ampere peak would pass through either element alone. Let's see what happens when we assume that 1 ampere is passing through *both* in series.

We would, by Ohm's Law, find 100 volts peak, in phase with the current, across the resistor – and by similar reasoning, we would find 100 volts peak across the capacitor also, but this would be 90 degrees out of phase with the current and so would also be 90 degrees out of phase with the voltage across the resistor as well.

What happens when we have two voltages out of phase with each other in the same circuit? Figure 4 shows some waveforms which may help us to see the result. When one of the voltages is at its peak, the other is just crossing zero. When the second reaches peak, the first is crossing zero. For a part of the cycle, both have the same polarity, and for a part of the cycle, they have opposite polarity.

But we cannot have *two* voltages in one circuit, not across the outside terminals of the circuit. At any one measuring point, we can have only *one* observable voltage and *one* observable current. Since we can imagine each of our voltages separately, let's stretch our imaginations a bit more and see what happens when we merge them together into a single waveform.

At point A, voltage I is zero and voltage

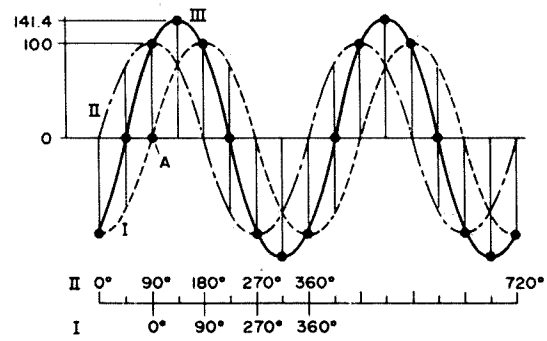

Fig. 4. Waveforms of voltages in circuit of Fig. 3 show what happens in combined circuit. Voltage I represents voltage across resistor, Voltage II is that across capacitor, and Voltage III is that across the total circuit. Voltage III is determined by adding together the values of I and II at each point along the time scale. Note that final voltage is halfway between original voltages in phase, and is greater than either alone but not twice as great as either.

II is at positive peak. The "merged" result (III) must be simply whatever value voltage II has right then. A little later, the two original voltages cross each other, one on the way up and the other coming down. Voltage III at this point must be equal to the sum of both, or twice as great as either.

In fact, all the way through the cycle voltage III must be equal to the sum of voltage I and voltage II. Where the two are of opposite polarity and tend to cancel out, read "difference" (most texts use the phrase "algebraic sum" to indicate that cancellation or reinforcement either can occur, depending on relative polarity).

And voila! Voltage III is still a sine wave, just like the two waveforms of which it is composed –but it's not in phase with either of them. It does, in fact, split the phase difference, so that it is 45 degrees out of phase with the current.

We still have one small insect in the unguent. Our original 100-ohm values were based on a 100-volt-peak source and 1 amp current. Voltage III has a peak value considerably greater than 100 volts. It works out to be 141.4 volts, if you care to measure it (and if our illustrator has drawn his sine-wave curves accurately).

However, in a series circuit, the total voltage across the outside terminals where we're observing voltage III must be equal

to that provided by the power source. That means that we can't have 141.4 volts here; we are limited to 100 volts for the total.

We compensate for this by assuming a reduction in current, and this is only reasonable since whatever the resistor turns into heat isn't going to be available to the capacitor. To cut the total voltage from 141.4 to 100 we can merely divide it by 1.414. This indicates that we should divide our current figures by 1.414 also, so that we have only 0.707 ampere peak instead of 1 amp.

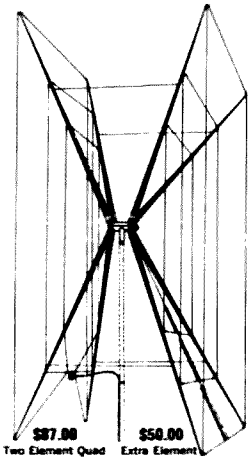
With 0.707 ampere through the resistor, the voltage across it becomes 70.7 volts peak. That same 0.707 ampere through the capacitor sustains a 70.7-volt peak potential across it, and if both voltage I and voltage II are 70.7 volts peak, then their combination into voltage III will produce 100 volts peak, and everything balances properly.

We have seen, through some illustrations and a lot of specific numbers, that 100 ohms of capacitive reactance combine with 100 ohms of resistance to produce a result different from either reactance or resistance. What is this result called?

Its name is "impedance," and like resistance and reactance, it is measured in ohms. The name "impedance" comes about because impedance is the combination of resistance and reactance, both of which impede the transfer of electrical energy.

How many ohms of impedance does our sample circuit have? We could take a stab at figuring it out by applying Ohm's Law to the figures we finally worked out of 100 volts and 0.707 amperes; this would give us a figure of 141.4 ohms for "R" – but it's impedance rather than resistance we're figuring, and "R" is the abbreviation for resistance. Impedance is always abbreviated as "Z," while reactance is "X" with a C or L subscript to identify it as capacitive or inductive.

That stab is exactly accurate, because Ohm's Law does work for ac circuits just as well as for dc if all the "R" factors are replaced by Zs. However, there are simpler ways of expressing impedance than by having to figure out all the currents and voltage drops in a circuit.



FIBRE-GLASS

GEM-QUAD

FOR 10, 15, AND 20 METERS

Never before has one antenna offered so much

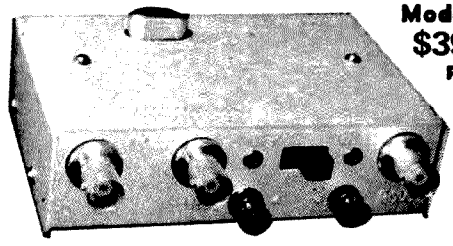
- The GEM QUAD is a two, three, or four element antenna designed to operate on ten, fifteen, and twenty meters.
- Forward gain for two element GEM QUAD gives maximum gain on DX, "where it counts."
- Optional third element (easily installed) has given optimum forward gain with a narrow forward cone of effectiveness, resulting in excellent rejection of unwanted signals.
- Front to back ratio designed for maximum signal discrimination.
- Toroid balun kit supplied for single feed line matching.
- Mounting spider of durable heavy duty aluminum alloy. 1½ inch o.d. stub facilitates easy mast mounting.
- Hollow spider allows insertion of boom for additional element.
- Fibreglass arms withstand 100 m.p.h. winds with minimum loading on tower (2.5 sq. ft. wind load area).
- Tridetic arm design (air passes through the arm). Low wind resistance eliminates need for excessive guy wires.

$87.00 Two Element Quad $50.00 Extra Element

Includes U.S. Customs Import Duty and Can. Federal Sales Tax – Shipped Collect

- Simple assembly and tuning instructions are supplied with every kit, showing measurements and assembly procedure. When assembled as instructed, tuning only takes a matter of minutes.
- Maintains rigid form continuously. Double "Cone-shaped" design maintains critical measurements under severe weather conditions. Completely weather resistant — will not freeze or crack.
- Light weight (complete antenna weighs 20 lbs., 3rd element 10 lbs.). Simple TV rotator will rotate antenna.
- Single 52 ohm feed-line for all bands. SWR of 1 to 1 easily obtained using ferrite Toroid Balun provided, (produces minimum harmonic radiation). Will handle maximum power input.

Can. Patent 794505 U.S. Patent Pending



Structural Glass LIMITED

20 Burnett Ave., Winnipeg, Manitoba, Canada

THE BEST

2 METER

CONVERTER

Model 407

$39.95

ppd.

144-146 MHz in, 28-30 MHz out

or 146-148 MHz with a second crystal

Available at $4.95 each.

A full description of this fantastic converter would fill this page, but you can take our word for it (or those of thousands of satisfied users) that it's the best. The reason is simple—we use three RCA dual gate MOSFETs, one bipolar, and 3 diodes in the best circuit ever. Still not convinced?Then send for our free catalog and get the full description, plus photos and even the schematic.

Can't wait?Then send us a postal money order for $39.95 and we'll rush the 407 out to you. NOTE: The Model 407 is also available in any frequency combination up to 450 MHz (some at higher prices) as listed in our catalog.

*New York City and State residents add local sales tax.

VANGUARD LABS

Dept. H, 194-23 Jamaica Ave., Hollis, N.Y. 11423

One of the simplest ways to express impedance, and one which is in wide use by engineers and sufficiently general use in the ham field to make it necessary that you know it, is not to combine the R and X at all into a single figure, but to express impedance as a sum "R ± jX." The sign is plus if X is inductive, and minus if X is capacitive (that is, the sign in the sum follows the sign of the reactance). This is known as the "complex" expression of impedance, because it's the form used in mathematics to express "complex numbers," but it's actually less complex than the arithmetic you have to go through to combine the R and the X into a single value of Z.

The impedance of our sample circuit, expressed this way, would be "100 – j100" ohms. The "j" is an indicator telling us that the number it accompanies is a reactance rather than a resistance.

For many purposes, this is the clearest way to put it. One of the major ham applications of "complex" impedance values is in rating feedpoint impedance of antennas and transmission lines. The object in this case is to get the "j" value to zero, which we can do by adding reactance of the opposite sign, and the "R ±jX" way of expressing the value tells us directly how much and what kind of tuning reactance is necessary.

The other way of expressing impedance reduces the sum to a single number, such as the 141.4 ohms we came up with a few paragraphs back. To be accurate about it, such a number must always be accompanied by its phase angle, so that the

Fig. 5. This "number line" is basis of graphical method of determining impedance values. It provides conversion from picture to actual values.

impedance of our sample circuit is actually 141.4∠-45° ohms. To show why the angle is necessary, and to show how to figure the number and angle, we're going to have to put it in some more pictures.

If you've been exposed to "the new math" either as a student or as a sidelines observer, you have probably met a "number line" already. If not, one awaits in Fig. 5. This is just a line divided into regular spaces, like a ruler, with zero in its middle. Each space to the right of the zero point is one more positive number, and each to the left is a negative number, so that the spaces run -4, -3, -2, -1, 0, 1, 2, 3, 4 . . . The idea is that this "number line" offers a picture of the way we count things, and we can use a number line to illustrate anything that is countable, which includes the number of ohms of impedance, resistance, or reactance in a circuit.

This "number line" idea is, in fact, the basis of all the graphs we use to show how quantities vary with respect to each other, because the two axes of any normal graph are simply crossed number lines.

We can cross two number lines as shown in Fig. 6, crossing them at their zero points and placing them at right angles to each other, to show how resistance and reac-

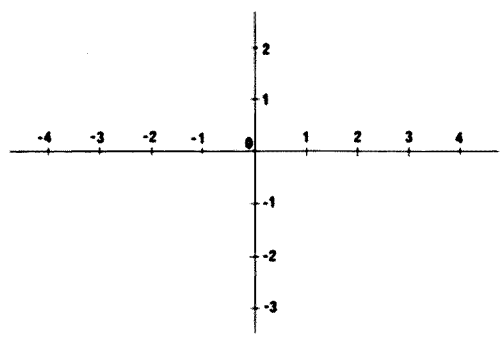


Fig. 6. Crossing two number lines at right angles gives us a "number plane" on which we may draw a graph. The two number lines provide scales for the graph.

tance combine. It doesn't really show "how," but as we shall see everything fits properly, so the idea is workable (the real "how" is the combining of voltages which we've already suffered through back in Figs. 3 and 4.) We shall call the horizontal scale the resistance or "R" scale and the vertical scale the reactance or "X" scale. "Negative resistance" is hard to find, so most of the time we'll use only the right-hand half of the resistance scale, but both halves of the reactance scale come

into play because of our convention that capacitive reactance is negative while inductive reactance is positive.

If we plot our 100 ohms of resistance from Fig. 3 and the -100 ohms of capacitive reactance on the graph of Fig. 6, we come out as shown in Fig. 7 with a pair of

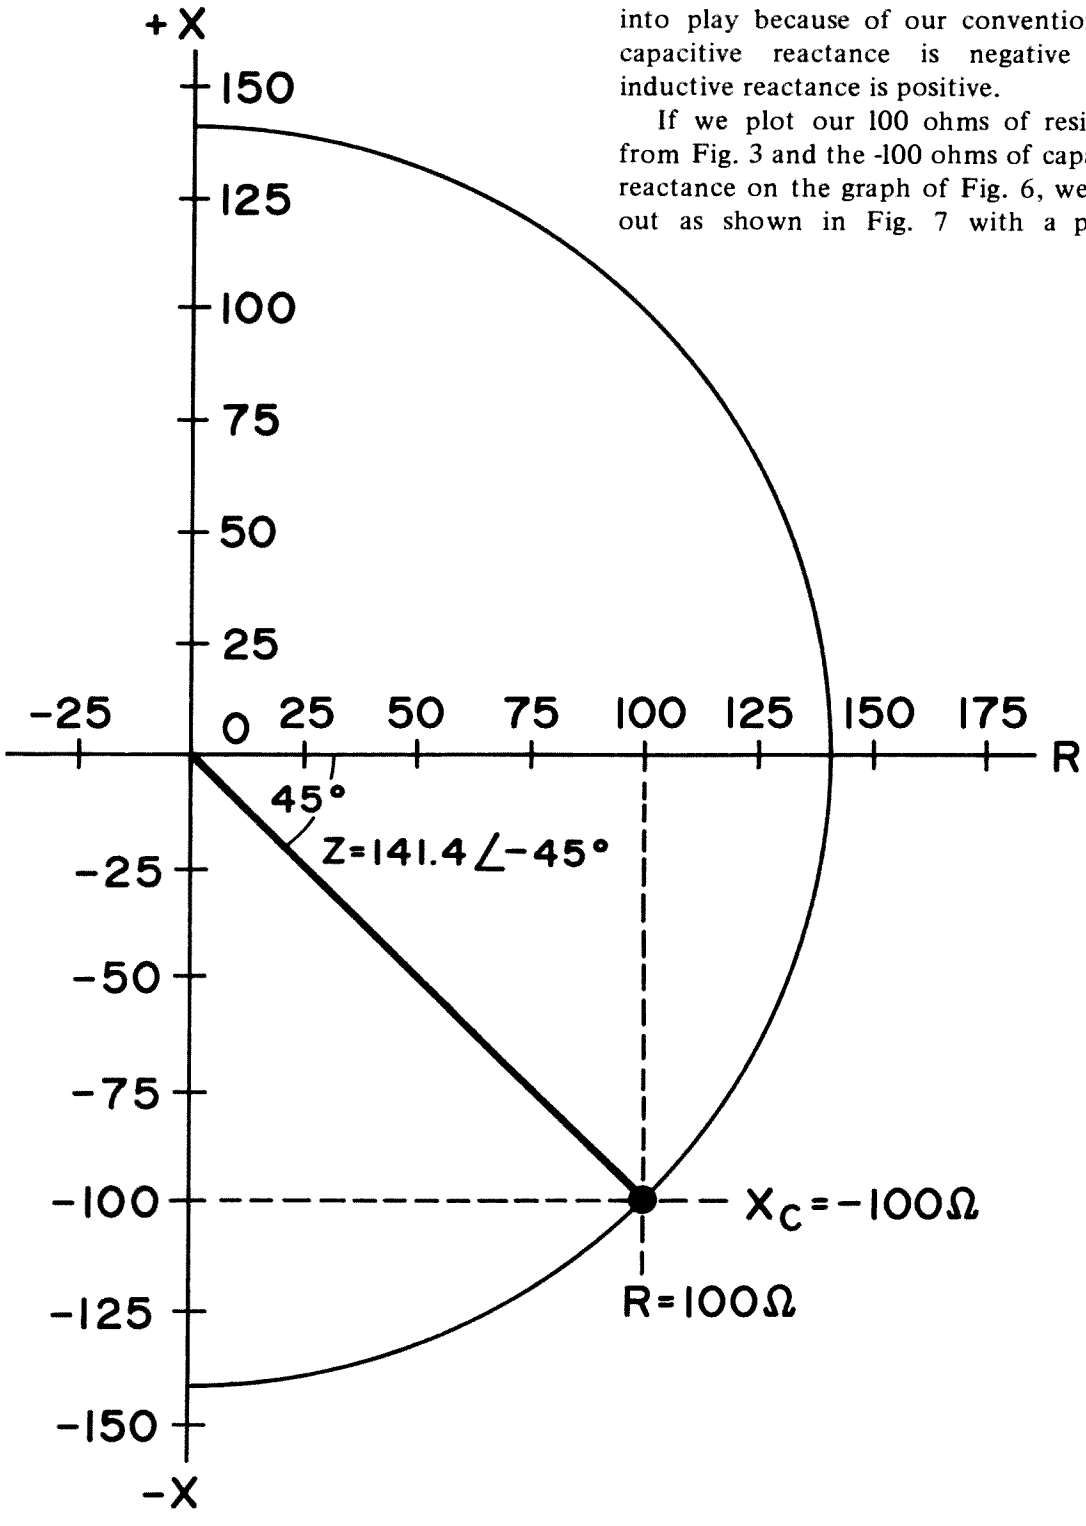

Fig. 7. Combination of 100 ohms resistance (horizontal scale) and 100 ohms capacitive reactance (vertical scale) gives us impedance of 141.4 ohms at phase angle of -45°. Text explains in detail how number plane is used to determine these values. Only right half of plane is needed because the left half represents "negative resistance" values, which are seldom encountered in practice.

dashed lines. The point at which these lines meet represents the combination of 100 ohms resistance and -100 ohms reactance.

We can now draw a straight line from this point back to the common zero point of both lines, and this single straight line represents the combined impedance of the circuit.

If we measure it, we will find (assuming that out illustrator remains accurate in his work) that it comes out to the same 141.4 ohms that we found by arithmetic before, and that it is at a -45 degree angle from the resistance scale.

These are the same figures we worked out previously, and so prove that in this case at least the graphical solution is right. It will be in all cases, because the graph is an exact chart for this particular problem.

Rather than drawing the graph and measuring the impedance line and angle, the normal practice is to calculate them from the relationships of the right triangle. The impedance line is the hypotenuse of the triangle, while the resistance and the reactance are its legs, so that Z^2 must equal $R^2 + X^2$. The trig functions of angles save us the need of working out all of this, because the phase angle can be determined by using the ratio X/R and finding the angle which has this ratio for its tangent. This angle is the phase angle of the impedance; the cosine of this angle is equal to the ratio R/Z, while the sine is equal to the ratio X/Z, so that with a table of trig functions we can get both Z and phase angle if we know R and X, or can get R and X if we know Z and phase angle. Figure 8 shows all the appropriate equations for converting from one way of expressing impedance to the other.

Before we leave Fig. 7, though, we should pause to see why it's so important to always include the phase angle when we're talking about impedance if we don't use the "complex " method.

We found, using Fig. 7, that the impedance of our sample circuit was 141.4 ohms of pure resistance, 141.4 ohms or pure reactance of either sign, or *any* combination of R and X which would bring us to a point lying on the circle in Fig. 7, because every point on this circle is 141.4 ohms away from the zero point.

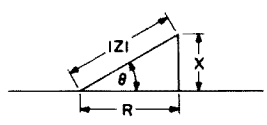
To make sure that the *one* point representing the combination "100–j100" ohms is understood, we must add the $<-45°$ phase angle information. This angle defines a line which starts at the zero point and goes on indefinitely at a 45-degree angle. However, the line and the 141.4-ohm circle can cross each other only once, at a single point, and so the two together make our impedance specification exact.

Now that we're on reasonably solid ground with resistance, reactance, and impedance, we can turn our attention to the question of how like reactances combine in series circuits. So long as it's the same kind of reactance, and assuming (it's important to note that this assumption can hardly ever be achieved in practice) that each reactance is completely independent of every other one in the circuit, they will simply add together like resistors would. What they will add, however, is their *reactance* rather than their capacitance or their inductance. Two capacitors, each having 100 ohms reactance by itself, would produce 200 ohms reactance when connected in series. A quick look at the reactance equations will show that this is the same as one capacitor of *half* the capacitance.

Most textbooks have a string of equations for you to memorize in this respect, in order to calculate the total effective capacitance of any number of capacitors connected in series. We're showing you the equations as Fig. 9, but you don't really need them. All you need do is figure out the effective reactance of each capacitor at

$|Z| = \sqrt{R^2 + X^2}$ $\qquad$ $R = |Z| \cos\theta$

$\theta = \text{ARCTAN}\left(\frac{X}{R}\right)$ $\qquad$ $X = j|Z| \sin\theta$



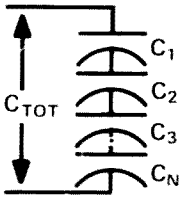


Fig. 8. These are the four equations which are used to convert from "polar plot" impedance expression (Z ohms at phase angle $\emptyset$) to "rectangular plot" or "complex" expression (R + jX). Vertical bars on either side of "Z" in equations mean "absolute value without regard to sign." Sketch identifies variables with respect to Fig. 7. "Arctan" means "the angle whose tangent is."

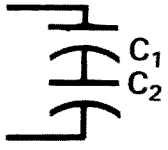

some arbitrary frequency such as 159 kHz (which will cancel out all conversion factors if you use it), then total up all the reactances and convert the resulting total reactance back to a single value of capacitance by reversing the conversion formula.

The same trick works with inductors – but if you use a frequency of 1/159 MHz for them, you'll find that it boils down to simply adding up inductances the same as for resistors.

The same trick works for parallel circuits, if we use a couple of other characteristics which are related to reactance and resistance but are not the same thing. These are "susceptance," which is the reciprocal of reactance, and "conductance," which is the reciprocal of resistance. Susceptance is abbreviated B, and

$$C_{TOT} = \frac{1}{\frac{1}{C_1}+\frac{1}{C_2}+\frac{1}{C_3}+\cdots+\frac{1}{C_N}}$$

$$C_{TOT} = \frac{C_1 \times C_2}{C_1 + C_2}$$

Fig. 9. General equation for determining effective value of several capacitors connected in series is shown at top. If just two capacitors are involved, simplified equation at bottom may be used. Since both these amount to an addition of susceptances (see text) and conversion back to reactance, they also apply to parallel resistors and to parallel inductances, by substituting "R" or "L" for "C" in the appropriate formula.

conductance as G. Impedance, too, has a reciprocal – "admittance," abbreviated Y. In parallel circuits, just total up admittances; in series circuits, total impedances.

Since like reactances in series behave just like resistors in series so far as total effective value is concerned, and since Ohm's Law holds for ac as well as dc when

WHEN IT COMES TO ANTENNA SYSTEMS... IS YOURS

a space problem? a budget problem? an applications problem? an installation problem? or simply a problem of where to buy?

Your one-stop solution is ANTENNAS, INC.
Exclusively specialists in radiating systems, complete systems or any component part.
Arrays—complete or in kit form, quads, yagis, dipole assemblies, verticals—fixed or mobile, towers, masts, rotors, guy and control cable, transmission line, coax relays and switches, connectors and adaptors, test gear, technical publications, corrosion resistant hardware, corrosion proofing chemicals, insulators, installation and wiring hardware, aluminum tubing and plate, wire, and much, much more.
If your requirements are for a complete system, major components, or the smallest yet important piece of hardware—

Our prices and deliveries are hard to beat . . . anywhere.

ANTENNAS, INC. Dept. B, 512 McDonald Road Leavenworth, Kansas 66048.

ANTENNAS, INC. can be your one-stop, single-source. Write today for our catalog . . . no charge of course.

we substitute "Z" for "R" in the equations, it's only natural to expect that ac voltage across a series string of like reactances would divide just as dc voltages do across a string of resistors.

The expectation is correct. In similar fashion, the current through parallel reactances of like sign will divide just as dc divides among parallel resistors.

All of this follows quite naturally from a conclusion which you may have already reached but which we have waited until now to point out: Both "resistance" and "reactance" can be thought of as being merely special types of "impedance," because any pure resistance can be expressed as an impedance of 0 degrees phase angle or "R± j0," while any pure reactance can also be expressed as an impedance with ±90 degrees phase angle (or "0±jX").

This way of looking at "resistance" and "reactance" as being merely forms of "impedance" lets us consider the ohm as always being a measure of "impedance," in all cases. The engineer's definition of both impedance and ohms is based on this; an "ohm" is the ratio of voltage to current in the circuit, and any quantity measured in "ohms" is an "impedance."

From these definitions, we get such factors as the plate resistance of a vacuum tube, the input and output impedances of amplifier circuits, and many more. We'll go into them in more detail later, when we need to. Right now, we're still working with the basics and building our foundations.

What about such things as "rf resistance" and "skin effect?" Both of these are effects due to impedance, and particularly to inductive reactance.

In the next installment, these areas will be covered in depth. Since they are associated inseparably with the theory covered here, the next chapter will be a continuation of "Part II" in the series, and the figure numbers will continue in the sequence already established.

To prepare yourself for the balance of the discussion, do a little extra studying of the Part I text involving flux lines and current flow. . . .Staff ■

constructive criticism will be found in QST, which puts the ball in our court.

Lobbying in Washington

If we don't have the support of our own country, how can we expect to get the support of others? We need the unqualified support of the U.S. delegation when the next ITU conference comes up. The U.S. delegation is by far the most important one at the ITU for two basic reasons. . .first of all because the U.S. has so many subtle means for coercing other countries into going along with its policies. . .and secondly because the U.S. team dwarfs all the others and thus has representation in force on every possible committee. Smaller countries have to choose which committees they will serve on, and just shrug about those they can't manage. The U.S. is on all of them and thus has a finger in every pie. This gives the U.S. quite an advantage over all of the other countries.

Do we have our government behind amateur radio 100%? No, we don't. Our government, like all others, bends in the direction of the pressures being brought to bear. The one radio service that is conspicuous by its total absence in the past has been amateur radio. Virtually our only friend at court has been Senator Goldwater, and he has done fabulously for us. But it is really unreasonable to expect Barry to neglect his responsibilities to Arizona and keep up the pressure for amateur radio that is needed to counter the constant pressures from all of the other radio services.

I wonder if you have any idea of what is involved in lobbying for amateur radio? This means getting in to see senators and representatives to discuss with them the importance of amateur radio to their state and to them. It means getting amateur radio achievements into the congressional record at every opportunity. Now, as you probably know, you don't just walk up to the senate office building and sit down to talk with a senator. He has a schedule that is filled sometimes for weeks ahead and you have to work your way into his schedule at his convenience, not yours. It also means a lot of waiting, because just before your scheduled meeting the senator will be called to the floor for an important debate or vote and you have to wait until he gets back or else get on the list for another appointment next week or even next month.

You have to do a lot of your work by mail, too. The senators will have questions that you will have to research for them. Most of them get letters from ham constituents every now and then and they want some way to get the right answers for these questions as quickly and simply as possible. You can help, but it means time and work. . .and letters. . .and phone calls.

All this is groundwork. Then suddenly along comes some legislation having to do with amateur radio. At this time you need every contact and friend you have made to get the bill into perspective and to round up the votes you need to get it through, stop it, or amend it. You have to know who to contact at the FCC to get the right answers. . .at State. . .etc.

Or perhaps an FCC docket comes up that is important. You can bet that pressure from congress will have a measurable effect on the outcome.

How many of you can tell me who this important man is that we have in Washington lobbying for amateur radio? Is there an ARRL representative working for us there? You know the answer is no, there is no representative of the ARRL lobbying for us in Washington. There is one man in the U.S. that is registered to lobby for amateur radio and only one. . . ***me!***

I make the two-hour drive to Boston, the hour flight to Washington, and get in to see everyone I can during the short times that I can get away from 73 and Radio Today, but I want you to know that you are leaning on a mighty weak crutch when you depend entirely on me to beat the drum for amateur radio. I would much rather spend my time up here in cool New Hampshire than down in sweltering Washington . . .and my wife feels the same way about it since she has to mind the store while I'm away. Please ask your ARRL director why our hobby can't do any better than me for a representative of amateur radio.

More JY1

Several amateurs, after reading my report on Jordan, called me long distance to thank me personally for what they considered the most important achievement of my trip. . .a vote for amateur radio at the ITU. Hundreds have called me on the air to thank me for giving them a new country. Letters of compliment continue to come in from all over the country (nothing heard from ARRL yet), plus one sour note from Dave Mann K2AGZ.

Dave writes that "All my Zionist friends have been giving me the business," because the JY article was "pro-Jordan" at a time "when shots fired in Jordan are killing kids in Israeli school buses."

Zionists, above all else, should not be so completely out of touch with what is really going on over there. I do not believe that the Jordanian army is in any way involved with the fedayeen commando attacks. With some 25,000 fedayeen overrunning their country, the Jordanians are virtually helpless to seriously curb these Palestinian refugees. The money and supplies for this guerilla army are provided primarily by Libya and Saudi Arabia, with none coming from Jordan, as I understand the situation. The fedayeen commandos are paid almost four times the money that the Jordanian army gets, by the way. And they are better supplied.

Where does all the money come from for the commandos? The path, as it looks to me, is first from your pocket to your local gas station or fuel oil dealer. From there it goes to the big oil companies. They send it to the Arab oil coun-

tries, who in turn send it to the commandos. I might point out right here that Jordan has no oil whatever.

Perhaps the serious Zionist would do best to consider an electric car, or at least one of the foreign cars that use about one third the gasoline that his Cadillac does.

Those of you who have been following the political situation in the Mideast know that the moderates in Israel and the Arab moderates are almost in complete agreement on solutions to the problems of Palestine. Unfortunately, the extremists on both sides are preventing the moderates from getting together and accomplishing anything. I don't think that anyone would characterize King Hussein as other than a moderate.

Indeed, early in June the gulf between the Jordan government and the commandos resulted in bloody battles, with hundreds killed in Amman and King Hussein almost assassinated. The announcement of more arms for Israel from the U.S. triggered off this fight, a reaction to the commando feeling that Hussein was too friendly to the U.S.

With Israel getting more U.S. arms, and with none being sold to Jordan, the U.S. may finally force King Hussein to make a deal with Russia, though he has obviously been extremely reluctant to do this thus far.

Bum Rap

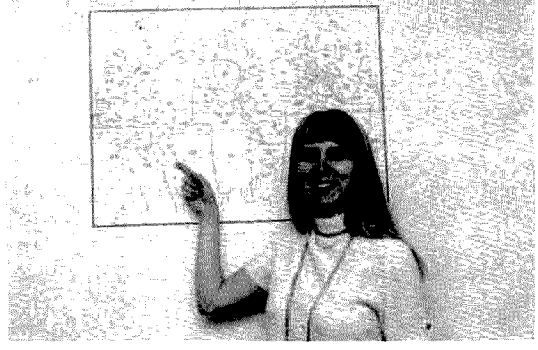
Reports are rampant that K2IXP (Larry) will be active from the Laccadives (VU4), but on the other hand many seasoned DX ops remember that VU2NR (Raju), the president of the Radio Society of India has been trying for several years to get permission to go there and without success. I may be doing Larry an injustice, but I was a bit annoyed to get the report that he had been invited to Jordan by King Hussein, only to be attacked as he tried to enter the country. I was there and talked with Larry when he was in Amman and I know what happened. The incident was unfortunate, undoubtedly, but it was nothing like that.

When I contacted Larry before my trip to Jordan he was operating as K2IXP/4X4 and mentioned that he and his wife might come over to Jordan while I was there. When he arrived in Jordan he got into trouble almost immediately. I was in the middle of my conferences with the government heads while setting up the Royal Jordanian Amateur Radio Society and couldn't get away to see him. By the next day he had left the country.

Larry explained on the phone that he and his wife had been in downtown Amman looking around when one of the commandos attacked him. Other commandos came immediately to his rescue and rushed him to the hospital for repairs. After a good deal of checking on this I found some confusion about whether the argument started over his wife getting pinched (she was wearing a short miniskirt, which is bad taste in Amman) or his taking pictures of some commandos. At any rate the commandos were most apologetic about the matter and offered to escort them anywhere they would like to go in Jordan.

When I mentioned the incident to His Majesty that evening he said that he had heard nothing of Larry's coming and offered his sincere regret for the trouble and asked his secretary to check the next morning and see what could be done to help. Pat checked and found that Larry and his wife had already left for Syria.

The Opinions Expressed, etc.



Unlike any other ham magazine that I can think of at the moment, the opinions expressed in articles, letters, and editorials, other than by the publisher, in 73 do not necessarily (or even usually) coincide with those of the publisher. Only 73, of all the magazines, recognizes the importance of an outlet for more than one person to make a fool of himself.

How About a Sked?

Since I would like to get info of interest for our news pages, DX news, and stuff like that, perhaps it would expedite matters if I could get on the air on a specific frequency at a specific time fairly regularly. Let's give it a try and see how it works.

On nights when Lin doesn't yank me off to the movie or I'm not out of town at a hamfest or something, I'll listen on 14,300 at 0200 GMT for any calls. . . . Wayne ■

Article Nonpayment

73 has received a number of letters from reader-authors who complain that they are not always paid for their efforts. Many of those who write ask that their names and letters be held in confidence (understandably). Others are quite willing to be quoted. Here are a couple of letters in the latter category. These are representative letters of complaint. For obvious reasons, 73 has not been able to verify the claims.

. . .Ed.

I wrote an article for CQ two years ago and they still haven't paid me. You can find my article in CQ, Nov. '68. The amount is over $150. The attorney general informs me that he can do nothing about it, so feel free to use my name and article and date as you see fit.

Neil Iverson W7PVF
2640 S. 133
Seattle WA

You might contact postal authorities and see if advertising author remuneration without following through might constitute mail fraud.

Could 73 suggest an attorney who has had experience handling cases against CQ? I am interested in bringing "breach of contract" proceedings against Cowan over a booklet manuscript of mine he contracted to publish but won't get on with and refuses to return my material.

John Schultz W2EEY
Arabella St. 18
8 Munich 81, Germany

Wayne is answering your letter personally.

JY1

Hooray for JY1. Now stop playing favorites and get thee over to 4X4-land pronto. Lox and bagels to you.

Anonymous
Clifton NJ

Wayne had complete control of a difficult (DX) situation. It was a real pleasure to hear him. . .in his quiet and forceful way. . .chastise inconsiderate breakers from other areas who kept calling when he specifically called for *sixes*. . .

Steve Cerwin K6OJO

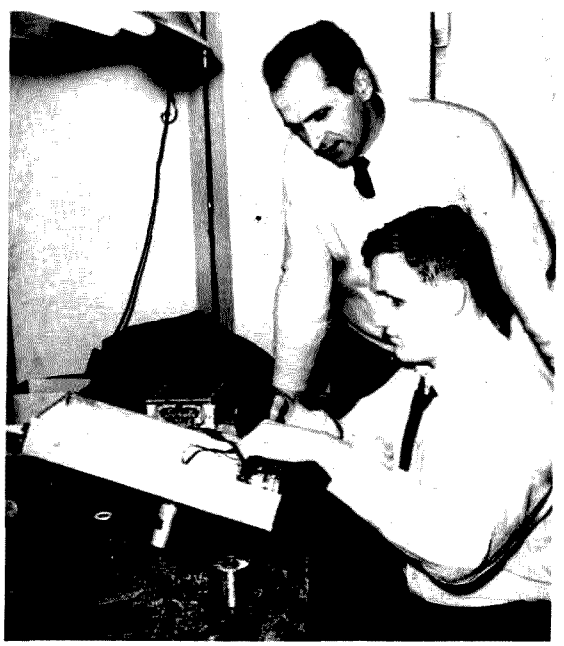
I'm quite sure that Wayne did a masterful job in getting the Jordanians on the air by getting them started with two classes of license – also

(cont. on page 88)



Club for Blind Amateurs:
K1TPX Perkins Radio Club

The hobby of amateur radio has appealed to some students of Perkins School for the Blind in Watertown, Mass., so much so that they have formed a radio club. There are eighteen members in the club with president George Henault presiding. He is shown here operating the club station, consisting of a Central Electronics 200V with the matching 600L linear. This equipment lends itself well to operation by the students for there is no loading involved. The receiver is a Hallicrafters SX-101A. The antenna is a Mosley TA-33 beam on a 75 ft Tristao crank-up tilt-over tower. Mr. Paul Bauguss, WA1CAQ, the faculty adviser, is responsible for much of this fine gear.

Dick Gonyea, an electrical engineering student at Northeastern University volunteers three hours a week to help the younger members achieve their novice licenses. Glenn Grimes and Paul Burkhardt are studying Braille schematic diagrams under Dick's watchful eye.

Ted Filteau, a previous president, is learning to build a transmitter with the help of Jim Dossett, KITIH. Jim makes available his Thursday evenings in order to help the members at Perkins. The simple CW transmitter that Ted is building as a project will be operational when finished.

The Perkins' Radio Club KITPX has been in existence for about seven years and shows no sign of diminishing.

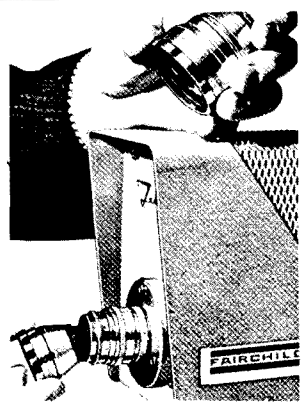
for (opening the door for) any ham visitors that may be planning on visiting Jordan in the future. I commend 73 for having a very good cover picture of King Hussein.

Ken Mahoney K6OPG
455 41st Ave.
San Francisco CA

Enjoyed reading about King Hussein. I regret the problems he's had lately. Hope he comes out on top of it all.

Stewart MacKenzie
16182 Ballad Lane
Huntington Bch CA

Thanks to Wayne for what he did for Hussein and for all of us. In impact, it dwarfs another $50 million in lend-lease or whatever the dole is called these days. How about sending the King a decent tribander and rotator so he can hear us a bit better? Could be done on a contribution basis so that it is a personal, men-to-man gift from American hams. (It would) keep out commercial interests and show the man that individuals in the U.S. admire him and can see past politics and apparent government favoritism.



Ned Raub W1RAN
207 Thames St.
New London CT

My appreciation for Wayne's untiring effort in the area of bringing about a better understanding between the U.S. and other countries. With this kind of leadership in our amateur radio ranks, we find a "challenge" and "incentive" to follow up with each opportunity to bring about deeper understanding and brotherhood. It is with renewed interest that I now operate my station. It is good for you to know that you have much support in your efforts to strengthen ham radio at home and abroad. The amateur ranks need what 73 is giving!

Mr. Mann. Please cancel my subscription and refund me the balance due.

Charles V. Thomas K5EDI
327 Mason
Hot Springs AR

Hancock and Adams were anti-government. They were members of a very vocal minority, and were, only after much persuasive strategy, able to swing public opinion their way. The govenor of Massachusetts ordered their arrest for insurrection, treasonous acts, etc. The chief differences (as far as I can tell) between Hoffman and Hancock are the tactics and motivations. Seale and Hoffman could hardly be considered as heroes.

. . .Ken

This expresses my appreciation for continuing excellent coverage of the significant happenings and affairs in Amateur Radio. 73's objective and "involved" editorializing is in refreshing contrast to the trite, trivial, and paternalistic editorial exhortations of QST.

J.W. Sandbert, K6HE
1138 E. Rustic Road
Escondido CA

Mixed Metaphors

Dear Editors: Been reading 73's comments on ARRL. Now I have no howdy do for either of you. But I think you are looking for someone to fight a war for you. If you have all the answers, why in Hell don't you grab the bull by the horns and take over. You remind me of a young snotnose – along with the ARRL! Grow up. Kid, if you can't face the music, get out of the competition game. Soon as I find the QTH for "past life" extension am going to subscribe for life just to see how long you take growing up.

Mr. L. Venzor WA9PAH
3011 South Ave.
Chicago IL

73's Study Guide

I am pleased to renew my subscription to 73 for another three years. 73 has shown a vast improvement over the last several years and is making a great contribution to amateur radio with the license study course you so wisely published. I find that other magazines are either too technical or have just deteriorated. I am not renewing my subscriptions to these other magazines when they run out. I am now a life member of ARRL and will continue to support it. Keep up the good work.

Alfred Smith WA2TAQ
11 Irving Place
Lynbrook NY

Your theory on how to pass exams should be put in a book form. It's the best thorough explantion I've ever seen. Your SSB article cleared up a lot for me.

J. Brousek
4704 Bragdon

Regular price- 23¢ per foot. Our price 5¢ per foot $3.00 per 100 ft.
455 Khz ceramic filters type BF-455-A. These filters will help to sharpen the selectivity of most sets using 455 Khz IF's. Use across cathode bias resistor in place of a capacitor, or in transistorized sets, across the emitter bias resistor. Impedance is 20 ohms at 455Khz., DC resistance is infinite. Impedance increases rapidly as you leave 455 Khz. Plan your own LC filter circuits at very low cost.
10 for $1.00 25 for $2.00

TOROID POWER TRANSFORMERS

T-2 This toroid was designed for use in a hybrid F.M. mobile unit, using a single 8647 tube in the RF amp. for 30 watts output. Schematic included. 12 VDC pri. using 2N1554's or equivalent. Sec. #1 500 volts DC out at 70 watts. Sec. #2 -65 volts DC bias. Sec. #3 1.2 volts AC for filament of 8647 tube. Sec. #4 C/T feed back winding for 2N1554's. 1¼" thick. 2¾" dia. $2.95 ea. -2 for $5.00
T-3 Has a powdered iron core and is built like a TV fly back transformer. Operates at about 800 CPS. 12V DC Pri. using 2N442's or equivalent. DC output of V/DBLR 475 volts 90 watts. C/T feed back winding for 2N442's. $2.95 ea. -2 for $5.00

TRANSFORMERS

P-7 117 VAC Pri. Sec. #1 185 VAC @ 120 ma. Sec. #2 6.3 VAC @ 4A. Double Half Shell Mail Box Type. SX 146 type. $2.75 ea. -2 for $5.00
P-9 117 VAC Pri. Sec. # 900 VAC @ 300 ma. Sec. # 2 100 VAC @ 10 ma. Bias. Sec. #3 12.6 VAC @ AMP. Wt. 16½ lbs. Double Half Shell $4.50
P-10 117 VAC Pri. Sec. #1 960 VAC C.T. @ 160 ma. Sec. #2 425 VAC C.T. and tap at 100 VAC 10 ma Bias. Sec. #3 12.6 VAC @ 4.5A Double Shell Mail Box type. Wt. 8¾ lbs. $3.75
Output transformers, all types 59 cents or 3 for $1.50
OT-1 Transistor TO-3 Power Diamond.. Imp. 15 ohms to 3.2 ohms DC Res. Pri. .6ohm. Sec. .3 ohm.
OT-2 Pri. imp. 7000 ohm. Sec. 3-2 and 500 ohm for Phones or 70 volt line 3 watts. Full shielded Double Half Shell.
OT-3 Pri. imp. 5500 ohms. Sec. 3.2 ohms. SC122 type.

All prices F.O.B. All weights listed are net. Please allow for packaging. Please allow enough for postage. We will return any extra.

of radio principles and practices as I've seen. It certainly doesn't bear much resemblance to that tortured language in the ARRL Handbook or my college textbooks.

David Halliburton W9EQG
10809 Old Coach Road
Potomac MD

I am a newcomer to ham radio and I would like to thank you for your *Advance Class study guide.*. I became interested in radio years ago but did nothing about it. But in November 1969 I purchased two code practice tapes (Codemaster) and your study guide. As a result of my practice and study, I was able to breeze through the Advanced ham license test in February.

Edward H. Stiles WA6RDB
6529 Hillgrove Dr.
San Diego CA

Thank you very much for providing the Advanced & Extra Class study guide. I failed the Advanced the first time, but after reading your study guides I passed them both! I operated CW 99% and could not bear to lose the best parts of the bands. Otherwise I doubt if I would ever have sought the Extra Class. Thanks again.

Ken WA9OQE

ZIP Codes

Of late we are getting a lot of mail, postcards, etc., in which some of our inquirers who write in for catalogs, as a result of our ad in your publication, are not putting on their ZIP code. They are not writing legibly, some of the handwriting we cannot decipher.

It costs money to look up the ZIP codes-and everyone has a ZIP code. Some people put down incomplete addresses, box numbers, some box numbers omitted completely, sometimes a duplication of a number that doesn't coincide.

Please emphasize the importance of ZIP codes to your readers.

Herman Lubinsky
United Radio Co.
Box 1000
Newark NJ

All right, who's the wise guy who is making it rough on our advertisers?

Ham Hospitality

I am very much interested in your Ham Hospitality Scheme, and hereby offer my home for any visiting ham, especially a married couple or a lady. My interest is ham radio and I am in timber business. XYL, 36 yrs. old, is interested in cooking, painting, and embroidery. Visitors and their children will be welcomed, and we can arrange for their accommodation if they are willing to share the bedroom with us. We will allow them to use one kitchen as our food (Indian) will be different.

This offer is made in a true ham spirit with no strings attached.

If they wish, they can bring one latest issue of their country's call book or a magazine. Hams from any part of the world are welcomed and will be made comfortable.

Jimmy J. Mistry
Bella Vista
Bandra Bombay 50,
India

With reference to several publications observed in the 73 magazine about accommodation for visiting hams, I wish to let it be known that visiting hams to Trinidad and Tobago are welcome at our QTH with such activities as: Island wide tour, DXing with rig in shack, meeting the local hams, living accommodations with meals only if necessary, help on current project in shack accepted but optional.

Victor L. Steele
96 Charlotte Street,
Port-Of-Spain,
Trinidad, W Indies

Powder Puffs

I read with interest the article by Dave Middelton W7ZC "Ground Support for the Powder Puff Derby," June '70. This issue is being called to the attention of all our membership so they can enjoy this feature.

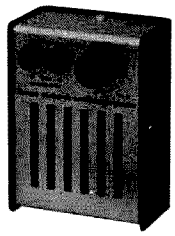
Penn-Jersey YL Club will be handling the terminus portion of the 1970 Derby at the 3M airport. The national chairman is one of our members and has appointed me as radio chairman for the terminus. This article gives us a complete scope of what we may expect during our coverage in this public service as a club. I am most anxious to meet some of the race officials, especially because our daughter is learning to fly and is also a licensed amateur. We hope to see future articles such as the one by W7ZC.

Rose Ellen Bills WA2FGS
17 Craig Place
Pennsville NJ

Hobby License

Your proposal for a no-code/no-theory "Hobby" license hit me like an invigorating blast of fresh New England air on a frosty Autumn morn. You are to be commended for this imaginative, yet practical, remedy to a hypocritical situation which has reached the bounds of absurdity. This proposal merits the wholehearted support of hams and CB'ers, League and non-Leaguers, alike. Even though the hour is late, it still just might be possible under this proposal to weld the ham fraternity back together again.

73 Magazine is certainly demonstrating its positive leadership in the field of amateur radio. The strong editorial positions are doing much to close the "communications gap" that our hobby has been plagued with lately. It's comforting to know that someone is more concerned with hams than simply "hamstringing" them . . .



Ed Collins WN6ABG

Kensington CA

QSL for Profit?

I must disagree and take umbrage with Mr. Shawsmith and his statements in his article "QSLing, Ham Radio's Own Con Game!" I have been a QSL manager for several years and sincerely believe that he has a nerve making such statements and you have the same for publishing them.

I do not intend to make a detailed legal reply to the unfounded allegations set forth therein. However, I can say that if it were not for the QSL manager, a great deal of the DXing as it is today just would not be. The only fault that can be found with the system is that there is such a demand among awards for QSLs themselves

mark 2 oscillator/monitor

- makes an audible tone to monitor the RF of any CW transmitter from 10Mw to 1 Kw & 100Kc to 1000Mc, using only an 8" pickup antenna.
- can be self-triggered for code practice or the testing of solid state components and circuits.
- aids in tuning up & testing RF oscillator and power circuits.
- 4 transistor, 2 diode circuit, speaker, tone adjust, AA pencell, test tips, 8" ant., & magnetic base.
- cabinet is 16 gauge black & clear anodised aluminum, 3.4 x 2.3 x 1.2"
- US made & guaranteed for 1 year.

which makes it essential that they be possessed.

There is hardly any need telling you that if a DX station were obliged to handle the entire load of his QSLs he would have no time to operate. Then there is the little matter of expense to the station which desires the QSL. But to say that a QSL manager gains glory, financial remuneration, ego lift, is open to bribery, etc., is tantamount to libel against the majority of those hams who take their own time, generally spend their own money, and exert their effort to reply for the DX station.

It appears that the foreign amateurs do not understand that the U.S. does not have a free QSL bureau as most of the other countries have. Consequently, when the QSL manager receives hundreds of cards through the ARRL bureau for the DX station he QSLs, it costs him money to reply! This includes the SWL cards, which come in droves.

I fully believe that your author has some ax to grind with some QSL manager. But what I do not understand is why you see fit to print such stuff.

Gay E. Milius, Jr. W4NJF
1416 Rutland Drive
Virginia Beach VA

VK4SS's article really hit home. I have been an extensive QSLer during my 5 years as an amateur. I kept close track of the last 800 cards sent out, which netted 455 returns. I have noticed several trends in QSLing: Returns ranged from a low of 35% on 20m SSB to a high of 80% on 6m (SSB + CW). 40m was about 50%; 15m, 60%; 10m, 65%. CW on all the HF bands was slightly better. DX stations were surprisingly good at almost 70%, and that was by the bureaus. Of about 15 SASEs sent to managers, only one never came back. I never sent any IRCs and very few DX cards direct.

In my opinion the worse ones are the ones who promised QSLs but never sent them. For a while on 20m I asked everybody if they QSLed but it only raised returns a few percent. To those few who said they didn't QSL I still think you're cheap and lousy and no good but thanks for being honest and saying you don't QSL.

Stephen J. Powlishen WA1FFO
53 Oak St.
East Hartford CT

Grommets Spare Your Panel

Occasionally even the best builder will make a boo-boo which sticks out like a sore thumb. Here is a way to avoid one of the most common goofs and one of the more obvious to the casual observer.

Keep a supply of various sized grommets at your drill press and in the drawer with your hand drill. When drilling a hole in an area which for appearance's sake must not be scratched, slip a grommet on the shank of the bit. If you should happen to force the drill a little too much, and the bit breaks through violently, the chuck will not hit the chassis or panel and disfigure it.

NEW PRODUCTS

Schematic Digest Updated For Modern FM Units

As FM gains in popularity with amateurs, schematics and data covering the surplus commercial units seem to get ever scarcer. A company called *Two-Way Radio Engineers, Inc.*, in Boston, has been doing something to ease the situation: This company is publishing a very large (11 x 17 in.) 136-page volume of circuit diagrams, photos, crystal-ordering, and alignment information for most Motorola rigs made during the 1950s and 60s. The book has been updated to include info on even the very recent Motorola transistor rigs such as the Motrac and Motran versions. This new *FM Schematic Digest* covers all the popular models in the 50, 150, and 450 MHz ranges, and sells for $3.95 postpaid. Order from *Two-Way Radio Engineers, Inc., 1100 Tremont St., Boston MA 02120.*

RF Power Amplifier Features Small Size, Printed-Circuit "Coils," Miniature Construction

A unique device that should prove particularly appealing to the FM'er is a tiny (2 x 6 in.) rf power amplifier that will turn a 20 mW FM signal into 10 full watts. The class C amplifier uses silicon transistors throughout and incorporates inductive elements that are "printed" right on the fiber glass/epoxy board.

According to the manufacturer, the compact unit will produce up to 15W with 30–50 mW of rf input. It covers the 2 meter range from 143 to 149 MHz, and requires no tuning with respect to frequency. To be operational, all that's needed is a small signal, an antenna, and a 12V dc power source. Unit is said to be identical to the type featured in the manufacturer's line of "briefcase" marine radiophones. *Dynamic Communications Inc. 301 Broadway, Riviera Beach FL 33404.*

Contents

16 **Integrated Circuit CW ID Generator** **W7PUG**
Automatic identification for your station.

26 **Six Volts From Twelve Volts** **K3GSY**
Six buck solid state voltage dropper.

29 **The Indicating Oscillator** **KH6AF**
Another dipper circuit, 1–400 MHz.

32 **Tuning VHF Receivers** **K1CLL**
Clever infinite attenuator and oscillator unit.

35 **Code Practice a la Baby Talk** **W9PXA**
Everybody's doing it. . .

38 **Using Those Bargain ICs** **WA2IKL**
Three testers will test most ICs you will encounter.

45 **Repeater Antenna Separation** **K6MVH**
One of the easiest ways to improve repeater range.

54 **Diode Stacks** **W2BDG**
Replacing those high-power rectifier tubes.

56 **Deluxe Receiver Gain Control** **VU2JN**
Using one transistor and a zener.

60 **A New Approach to Communications Equipment** **K9ALD**
A call for manufacturer standardization.

64 **Reed Relays for Coaxial Switching** **W7CRY**
Work very well for UHF low-power applications.

66 **File Box Resistance Decade** **WB4ITN**
First in a series of file box test gear.

70 **The DyComm VHF–FM RF Amplifier** ..... **Staff**
Transistorized, 15 watts out.

74 **General Class License Study Course** ..... **Staff**
Part II, Alternating Current.

82 **What Really Happened to Hamdom?** **W9HBF**
The horrible truth about CB.

86 **Beer Can Two-Meter Coaxial Antenna** **WA0RWQ/6**
Drink you way to a good signal.

88 **Converting 24V Relays to 115 VAC** ..... **Douglas**
. . . using a couple of cheap diodes.

90 **Versatile 2m MOSFET Converter** **WB6YVT**
Low noise, high gain, ultra stable.

73 Magazine is published monthly by 73, Inc., Pine St., Peterborough, New Hampshire 03458. Subscription rate: $12.00 for three years, $6.00 for one year. Second Class Postage paid at Peterborough, New Hampshire, and at additional mailing offices. Printed at Menasha, Wisconsin 54952. U.S.A.

Entire contents copyright 1970 by 73, Inc., Peterborough, New Hampshire 03458.

Phone: (603) 924-3873.

We do not claim that subscribing to 73 will make you wealthy, yet we cannot overlook the many reports we have received from our subscribers telling us that soon after subscribing to 73 they found buried treasure, fell heir to a fortune, or discovered a pearl in their oyster. It is difficult to overlook the strange coincidence that the magnitude of their windfall seems to always be in direct proportion to the length of the subscription taken to 73. Is a subscription to 73 really a money magnet? Can you afford not to make sure about this? Turn to page 98 please.

HAM SATELLITE FUTURE BRIGHT

Amateur satellite Australis–Oscar 5 has contributed significantly to plans for future satellites in the amateur service. It was the first OSCAR satellite to be launched by NASA; this is an important milestone since secondary payload space is expected to be available on future Thor-Delta launches as the payload capability of that rocket continues to be upgraded. Thus, the next OSCAR satellites under development by AMSAT are being designed specifically to interface with Delta launch vehicles.

The precedent of the command capability proven in the AO-5 mission is very significant, particularly in planning for long-life, solar-powered satellites in the amateur service, and in preparation for the 1971 ITU World Administrative Radio Conference on Space.

The use of command systems should prove a feasible alternative to the adoption of absolute power flux density limitations, so that satellites in the amateur service can be turned off upon command in the event of interference to other services operating in the shared amateur bands. The success of the Magnetic Attitude Stabilization

Members of the Antique Wireless Association admire a rare de Forest radiophone made in 1920 and used by many pioneer stations. WWJ at Detroit used this model when it first went on the air in September 1920. The rig's input power was about 20W. Left to right: K2NP, W2NSD, W2QY, L. Peckham, and K2BX. (Photo courtesy W2KE.)

FCC Steps Up Drive To Nab Violators

Paul J. Bedoian WIHRJ, of Newington, Connecticut, was cited by the Federal Communications Commision for "repeated violation of Amateur Rules, Section 97.7(b)." According to an FCC public notice, Bedoian operated his station "on a frequency not authorized." The FCC report listed the fine at $100, but gave the amateur 30 days in which to respond to the allegation.

In Monroe, Michigan, Richard Brown WA8YDZ was also cited for the same violation, as was Paul Angelides WA2YHK, of Middle Village, New York, and George White W1MPW, of Waterbury, Connecticut. In all cases, the fine was listed as $100.

The FCC doesn't just issue notices

System demonstrated that this technique is a most attractive one for future satellites.

The precedents established in international group cooperation among amateurs, and the training and educational benefits derived from the design, construction, testing and flight of AO–5 will also be of great usefulness in future radio amateur satellite projects. (Material furnished by AMSAT Newsletter.)

American Radio Club Formed

A small group of active amateurs gathered recently to see if they could provide the nucleus for action that seems needed to further the interests of amateur radio in the U.S.

A group of basic goals was agreed upon:

1. To work toward getting more amateurs in the U.S.
2. To recommend band allocations relevant to current use.
3. To protect the future of our hobby in Washington.
4. To protect the future of our hobby in the ITU.
5. To encourage discovery and development by amateurs.
6. To work with all other clubs and groups to strengthen amateur radio.

It was decided that the editorial policy of 73 Magazine best reflected the nonpartisan approach to amateur politics and that this magazine would be designated as the official club bulletin, providing this was agreeable with the publisher (it is . . . pub.).

The American Radio Club will accept bids from groups of amateurs interested in establishing Chartered Regions of the Club. A list of the founding members, the area included in the Chartered Region, the proposed Club, c/o 73 Magazine, Peterborough, N.H. 03458.

US Ham Mag Wanted by Reds

73 frequently gets letters from the Iron Curtain countries saying that it is impossible for the amateurs there to send money for subscriptions to 73, yet they find the magazine of tremendous interest and each copy is almost read to pieces it goes through so many hands.

If you would like to sponsor a subscription for a club please drop us a note and include $10 for each three-year gift subscription. We will start down our list of requests and go as far as we can. We will also drop a note to the club telling the amateurs who you are so they can let you know that the issues are coming through and are appreciated. While they can't send money, they can send through some really great phonograph records, records completely unavailable here, and things like that as gifts of appreciation.

If you already have a club or individual you would like to sponsor, send along that name and address for us. They must be in a controlled-currency country such as Poland, Czechoslovakia, Hungary, Russia, etc.

Speaking of which, just to give a little political zing to anyone who thinks of the U.S. as being imperialist, it is interesting to note that the U.S. has gotten out of every one of the 21 countries it has occupied since the beginning of the war, while our friends in Russia have left only one, Austria, and that one under a great deal of political pressure. So much for the capitalist imperialists.

Unlicensed Radar Brings Challenge

A California resident, irate over a traffic citation, told city council this week he is going to enlist the aid of the Federal Communications Commission in his battle with the local police department.

Dale Rohde, of Cypress, claimed the city's police were operating radar equipment without a federal license when he was issued a speeding ticket July 3.

Unless all the traffic citations obtained in this method are dismissed, he said a federal warrant would be sought against the city for violation of a section of FCC regulations, which governs the operation of public safety radio equipment.

The maximum penalty for each violation, Rohde said, is a two-year sentence and a $10,000 fine.

"I hope you gentlemen realize a municipality in the San Francisco area wound up paying $28,000 in an instance similar to this," Rohde said.

City Administrator Robert Huntley said the unit is presently inoperative and "it did not have a license."

Huntley added that Chief Conner Collacott, however, was "under the impression" the unit had been licensed.

Rohde asked council what action it intended to take.

"What do you want us to do?" asked Councilman Frank Fry.

"I don't think it is unreasonable for all these citations to be dismissed," said Rohde.

Nevertheless, Deputy Dist. Atty. Richard Beacom indicated the DA's office is planning on prosecuting the cases whether "the unit was illegal or not."

and forget. A number of amateurs are now getting nailed for failing to respond to Commission letters. Dennis Mitchell WA8ROJ, of Milan, Michigan, has been ordered to "show cause" why his license should not be revoked. His violation: failure to reply to official communications. And Martin Higgins WA6AGX, of La Crescenta, California, simply failed to give the FCC some information that had been requested. He, too, has been ordered to show cause why his license should not be revoked.

The Commission has at long last begun to act on the many cases of on-the-air jamming taking place in the ham bands. Robert Brickey, of Orem, Utah, who is holder of licenses for W7QAG, W7ABU, and WA7BTS, has been ordered to show cause why all his licenses shouldn't be revoked for "willful and malicious" violation of Sections 303(m) (1) (E) of the Communications Act of 1934 and Part 97.125 of the Amateur Rules. According to the FCC report, Brickey's stations were used "to interfere with" radio communications or signals of another radio station.

RADIO ANTENNA SUIT

An injunction suit is on file in Superior Court in which the City of Fresno seeks to force Patrick C. Fennacy to shorten a crank-up tower from 71 ft to a maximum of 25 ft and to obtain abuilding permit for the structure. According to an item in the Fresno Bee, the suit alleges Fennacy built the tower after the Fresno City Planning Commission turned down his request to erect it so high. The suit says the tower is a public nuisance. The amateur who submitted this report to 73 also said that "ARRL is reported as being uninterested."

WORLDWIDE DX NEWS

INTERNATIONAL DX ASSOCIATION FORMED

If you have been listening on 14220 at about 2330Z for the past several months you have heard reference made to a new international DX organization currently in the formative stage. The history of this effort goes back over several years and is long and involved. Let is suffice to say for now that Aubrey Spear WA5REU, Arden Hopple W3DJZ, and Eva Perenyi PY2PE, are more or less at the bottom of the deal.

During the past several weeks a few ideas have begun to jell and we now have a rudimentary organization still subject to change on short notice. The dues are to be $2 per year, also subject to change on short notice. In my possession is a document which was formulated by Aubrey and about a dozen other well-known DX'ers last April at the Dayton Hamvention. This document proposes certain aims and objectives of the organization. Such things as international goodwill, promotion of camaraderie, and good fellowship among amateurs (and other such hogwash) are mentioned.

However, the real meat of the thing is Objective II, which states "To finance DXpeditions, to furnish radio equipment to deserving amateurs throughout the world who are unable to do so for themselves for one reason or another." In short, the objective is to place radio equipment where it will the address shown below. In any case, join the PRS gang (Pandemonium Reigns Supreme) on 14.220 MHz at 2330Z any night in the week. You can get the latest DX rumors for free. For example, I worked ZA1C at 1643Z on 21275 kHz July 5, 1970 and he is for real (maybe).

CW PRACTICE BROADCASTS?

One of the ARRL services that is helpful to virtually every prospective amateur is the Morse Code broadcasts by W1AW and W6OWP. There is really no reason why these two stations should have a corner on the code practice market.

Just as we have established a Technical Aid Group in the pages of 73 (TAG) for answering technical questions from readers, we would like to establish a Code Practice Group. If you are set up for sending code practice sessions with your station and are willing to establish a fixed and ragidly unchangeable schedule for broadcasting, please let us know your time, frequency and code speed to be transmitted.

CPG stations should have automatic means for sending code and a substantial signal. While we think that the best bands for code practice are the 80 and 40 meter bands, there obviously is a need for some service on 20, 6, and even 2 meters. We ask that all CPG stations register with 73 so their schedules can be published and that when they come on the air, they check the scheduled frequency for activity and settle in plus or minus enough to avoid jamming contacts or nets in progress.

We suggest that code practice sessions consist of both plain language and coded groups.

CAN THE FEDS SEIZE YOUR GEAR ?

Yes, they can. And sometimes they do. As in the case of CB "skipper" George Bennett, for instance. George, better known to the local CB crowd as "Unit 909," had all his radio equipment confiscated by order of the government.

The Detroit man had been convicted of violating a U.S. District Court injunction against operating an unlicensed CB station, and received a six-month suspended sentence and a full year's probation. Then they came and took away his rig.

The reason his station was unlicensed, by the way, was because his license had earlier been revoked. The reason: "... flagrant violations of FCC rules." But despite the revocation, the severe warnings from the Fed, and the court injunction, Bennett just couldn't keep his hand off the switch. Now he doesn't even have a switch.

ONCE AROUND THE WORLD... *W2NSD/1*

C31AH (Gaston), gets on now and then from Andorra, but he has so far neglected to contact me. C31, what kind of nonsense is that? That's worse than that old CR10 prefix. Gaston, by expect to zip on down there for the awards banquet October 22nd. Hope you can make it too; there should be quite an interesting bunch there. FW8BO has been on recently around

MICHIGAN HAM WORKS GERMANY ON VHF

Fourth-of-July F2 conditions permit intercontinental QSO on 6 meters

When George Kerr (W8QNY), of Jackson, Michigan answered a CQ on the 4th of July, he thought he was making contact with South America. It took a little beam-spinning before he discovered he'd made an F2 contact with an amateur in the northern part of Germany.

"His signal was weaker to the south," George said, "so I worked my three-element Telrex toward the east ... He got my call straight when I was beamed southeast."

George said he learned the fellow, Peter, was transmitting from Keil, Germany, and talked with him "for about 30 minutes before the band dropped out."

do the most good to eliminate the word "rare" in rare DX. Considerable satisfaction can be derived from helping individuals like Sid (ST2SA) get on the air with SSB equipment. As a matter of fact, an HW-100 is on the way to Sid at this moment. Several projects which are currently in the works are: (1) An antenna is being sent to Africa in a TY/TZ effort; (2) the such discussed equipment for ZK1AJ has finally been located in Christchurch and is again on its way to Manihiki, Niue, and Tokalaus; (3) assistance was furnished for the recent highly successful Zanzibar operation; and (4) the Albania effort by OH2BH was supported.

It is quite obvious that, should this organization hold together and become productive, the demand will far exceed the supply. An HW-32 plus accessories plus AC/DC power supply costs about $200, not to mention the devastating cost and problems of getting it where it will do some good. Obviously, it will take support from large numbers of DX'ers to handle many such projects. Herein lies the main reason for the formulation of this group. If, for example, 2000 DXers want to contribute $2 per year, several stations could be sprinkled around the globe. Substantial contributions could be made to other individuals and groups planning DXpeditions of their own. Then, when the bite is put on you, you can say you are a member of "International DX Association" and have already contributed.

A final charter, ground rules, officers, etc. are being worked. However, it will be several months before such a final document is ready for distribution. In the meantime, useful and interesting projects are under way. If you feel that you would like to join such an effort, send your $2 to me at the way, is QSL'd via REF.

EP2DX is on fairly regularly from Tehran. QSL to W3HNK for Rick.

Funny about some of the phonies ...1A1A came on and immediately every smart op knew that this was a lead balloon, yet some of the thicker oldtimers continued to create pileups for this sickee for days. Ambrosia Island, good grief!

Biu, PY4AP, points out that he is not the QSL manager for PY7AWD/Ø. This station is now operating as PYØ Box 2, Fernando de Noronha and should be QSL'd direct. He speaks no English, so good luck. The Bermuda contest was hurt a bit by poor conditions, though VP9's AT, BY, CP, DL, FU, GD, GE, and MI were very busy anyway. Everything being equal, I 1200Z on 250. AX9KY on Cocos can be heard about the same time. 4S7AB is on 15 these days. FG7AC has been busy with all those DX'ers who need Guadaloupe, and there are thousands. VR5LT, Bill, Box 49, Tonga, South Pacific, was listing it up with W5GG doing the honors and gladdening a lot of hearts at 0330. There hasn't been much on from there since the old Miller daze. A CQ directed at the Middle-East brought an answer from 7X2SMA In Algiers (P.O. Box 2), where Boualem is doing his best with low power AM. 5R8AP (Buddy) has been on often recently, working the pileups by the prefixes. Nice signal and QSL to WB4GQH. By the way, when you are in Bermuda you can look up the local amateurs in the Yellow Pages under "Ham Radio."

OF LISTS AND SUCH...

The International DX Association meets nightly at 2230 on 14.220 for an orgy of list-working rare ones or else an orgy of boasting. Either way it is fun. They also get in a little time to scheme up new DXploits, figure where they can send a rig that will do some good, etc. Check in with K3RLY or PY2PE. Eva puts a horrendous signal into the entire U.S., so you can't really miss her charming voice and wry wit.

The other night the list featured a quickie with CE9AT down in the South Sandwich Islands. There are a few spots rarer than that, but only a few. The night before they were making the same scene with XT2AA, another beaut.

Lists are the order of the day for working 5R8AS, Chet Cunningham, down in Tananarive on Monday nights. He'll be there until December if you need a 5R8. Check in with Herb W6FQ at 0400 on 14.220. Chet is the director of the NASA tracking station down there.

Some ops are discourteous enough to get on the list, wait their turn, and then take the time of those still waiting to tell the DX op that they don't like lists. Bad manners. Boorish. Ugly. Okay, there are several ops that find their ego offended by having to get in line with the ordinary run-of-the-mill DX'er. They would much rather smash through a pileup to get their rare ones. It satisfies their need for prestige and proves their superiority to themselves and everyone else.

It all makes the list seem more worthwhile when you think it over.

ALBANIA ACTIVATED

Martin, OH2BH, operated for several hours from inside Albania in mid-July, giving some 700 enthusiastic DX'ers a contact with this rarest of countries.

Amateurs have been trying for many years to get permission to operate from Albania, but there have been no legitimate operations for at least 25 years. The few clandestine operations were short-lived, though they have been accepted by the ARRL for country credit.

There is some question about the validity of the OH2BH operation as far as official permission is concerned, with some interested parties being quite convinced that this operation, like its predecessors, was cladestine.

The cables received by amateurs in Finland and Sweden were short and perplexing: "Demonstration over, rig lost." The fact that Martin was able to return to Finland from Albania lends credence to the opinion that this might have been a legal operation. Word has it that, legal or illegal, credit will be given for ZA by ARRL to the 700 lucky ones who got through the pileup.

Foreign 73 Agents!

Please include call letters on all inquiries about subscriptions. 73 files subscriber names according to ZIP codes, but since foreign countries don't use ZIP, the only logical file system is by ham call. A mention of the call will save a tremendous amount of time in the troubleshooting department.

Thanks.

FCC-APPROVED ID FOR CONTESTS

by James E. Barr
Chief, Safety and Special
Radio Services Bureau

Since the fall amateur contest activity will soon be here, a number of amateurs may be interested in a resume of a recent explanation of what the Commission considers to be an acceptable station identification, as follows:

For compliance with rule Section 97.87(a), the last transmission of the exchange of transmissions with another station must include the "other" station's callsign. For example, "BK 589 CAL TU DX1DX de W6XYZ K" would be in compliance with $97.87(a). When there is a need for identification of the "other" station in an exchange for the benefit of our monitoring facilities, it is most likely to be heard if it is in the last transmission or at the end of a long single transmission.

Where the transmissions of an exchange are very brief, such as the typical contest exchange, if it is less than 30 seconds duration, the entire last transmission is considered the "end of the exchange" for the purpose of compliance with $97.87(a). Provided there is no mistaking which is the transmitting station's callsign, the callsigns may be anywhere in such last transmission. While the rule no longer gives examples, continuation of the traditional practice of placing the transmitting station's callsign last or preceding it by "de" is acceptable for this purpose.

Examples of acceptable end-of-exchange transmissions of less than 30 seconds are:

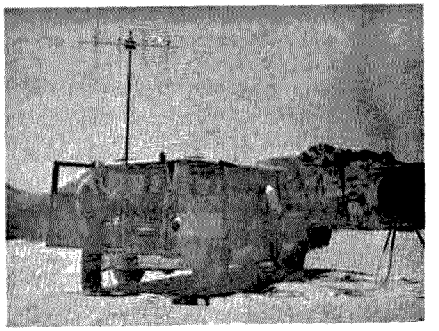
"CS1DX de W6XYZ 589 CAL BK"
"DX1DX W6XYZ 589 CAL K"
"DX1DX 589 CAL de W6XYZ K"
"DX1DX 589 CAL W6XYZ K"
"589 CAL DX1DX W6XYZ K"

For telephony, the voice equivalent of the foregoing examples may be used, substituting "this is" or "from" for "de," etc.

PRESS LETTING HAMS DOWN ?

The Society of Wireless Pioneers has expressed concern at the failure of the press and all media to mention or recognize the vital part radio officers play in the saving of lives and property during emergencies.

A case in point, according to an SOWP news release is the sinking of the *S.S. Badger State* Dec. 26, 1969, in which radio officer William Lafay-



"Trader Jim" Suffers Fatal Heart Attack

James S. Sommerville, (W9WHF), known to thousands of amateur radio and Citizens Band operators the world over as "Trader Jim," died recently of a heart attack.

Mr. Sommerville was a senior technical correspondent for Allied Radio Shack, Chicago. He acquired the nickname "Trader Jim" during the years that Allied was active in the trade-in communications equipment business through the mail.

An active Ham for more than 33 years, he had an earnest desire to help young people get started in amateur radio.

ATV MOUNTAINTOPPING

Three enterprising television amateurs – Dick Nickel (W6PCQ), Chuck Phillips (WB6WPQ), and Dan Fix (WA6DNY) – escorted their portable television and radio gear to the top of Santa Monica Mountains as a project of the ATV Club of Southern Calif. The reason for this tiring trip was to create wider interest in amateur radio through the modern concept of amateur television.

Mountaintopping is a standard for amateur radio activity on Field Day. However, amateur television is another story. Aside from the normal problems, there are sync pulses and video scanning, all of which must be generated or must be compatible with the 60 Hz commercial electrical line frequency.

The only source of electrical power used was a 12V electrical system from the 1969 Dodge van which was their only transportion. A 300W 12V-to-110V inverter furnished the end power source to the radio and television equipment. This supplied enough power to alternate between the available equipment.

A FAREWELL TO A PIONEER

by Mrs. Patricia Armstrong

In a geriatric home in Melfort, Saskatchewan, Canada, an event occurred that in one way was not important outside a small family circle, but in another was important to all hams everywhere. This was the death, in his seventy-third year, of Oscar Olson, a radio ham of forty years standing. Like the majority of his fellows, he was known locally by his name to only a few people, but internationally to many by a set of letters and figures. (Oscar's were VE5DS.) Is his passing not an occasion for North American hams to lay aside their microphones, hush the clatter of their code keys, and pay a moment's silent tribute to members of a fast-disappearing group: the pioneers of our own profession?

Okinawa Award Rules Change

The Okinawa Amateur Radio Club has recently revised requirements for the Okinawa Award, as follows: 25 QSLs are required for applicants from KR6 and KR8; 10 QSLs are required for BV, CR9, DU, HL/HM, JA/KA, KG6, VS6, W/K applicants. For the best of the world, 5 QSLs.

KR6 & KR8 applicants must submit cards for verification. For all others, send only a logbook extract with signed confirmation that required QSL information had been reviewed and verified by two licensed amateur radio operators, or by an official of a recognized radio club or society.

Send all applications, together with $1 (U.S.) or 10 International Reply Coupons, to QSL & Awards Manager, Okinawa Amateur Radio Club, Box 465, APO, San Francisco CA 96331.

ette lost his own life but was able to send the SOS which resulted in rescuing 14 members of the crew, including the captain.

Checking into the matter, the Society found that Officer Lafayette carried out his duties in an outstanding manner and he was complimented by all who worked with him in the handling of this emergency. *However* . . . not one word of this man's heroic devotion to duty found its way into press releases. Nor did any of those rescued give him recognition in their press interviews.

The Society suggests "monitoring" of press releases in newspapers, magazines, and other media, and contact the editor in the event of such omissions. The anonymous spokeman for the Society of Wireless Pioneers said. "We are proud of our heritage and the many brave and valiant men who have lost their lives in carrying out their duty." *What more can one ask?*

New Transistor Runs 90 W OUTPUT on 2m FM

A new silicon rf power transistor from Motorola (type MM1552), is rated at 90W peak output power, with an rf input of 18W, according to Jack Jaques, engineering director at Motorola Semiconductors,. of Phoenix, Arizona.

Intended for use as high-power Class C amplifiers for 100–175 MHz frequencies, the transistors have the high peak power capabilities and breakdown voltages required for AM service. The MM1552 permits close to 100% modulation with a 25W carrier at V_{CC}=13.5 Vdc. In FM or CW service, the new transistor is capable of a *continuous* 75W output at 150 MHz. The 65 V BV_{CES} of the MM1552 permits high level modulation with a 13.5V power supply or series modulation with a 27V supply. The transistor derives its electrical ruggedness from "balanced emitter" construction – it can withstand all conditions of load mismatch in AM service, from short to open circuit. Much of the fine broadband performance of the transistor comes from its low-lead inductance *stripline* package. The price is $43.50 each. An application note describing at 25W, broadband, amplitude-modulated transmitter employing the MM1552 may be obtained by writing Motorola directly.

New Mexico Hamfest To be Biggest Yet

The Albuquerque Amatuer Radio Club and Caravan Radio Club of New Mexico will sponsor the New Mexico Hamventon at Albuquerque, New Mexico on September 18, 19, and 20. This will coincide with the New Mexico State Fair which is being presented from the 17th through the 27th of September.

The Hamvention headquarters will be at the Holiday Inn East, East Highway 66. There will be a banquet on Saturday night (September 19) in the main ball room of the Holiday Inn. There will be lots of door prizes, Gabfest, flea market, and lots of fun. Technical sessions will be presented in the areas of VHF, FM, SSB and other subjects. There will be MARS meetings and the VHF FM Society of New Mexico will have its first formal meeting. Planned guests include Ken Sessions (Repeater Handbook) and Bill Orr (Radio Handbook).

Talk-in frequencies will be: 3990, 7293, 14345, and 29600 kHz (AM and FM), 146.34–146.94 MHz (Repeater), and 146.94 MHz (direct) NBFM.

For further information and registration, contact Ray Hill, W5SDM, 9016 Los Arboles Ave. NE, Albuquerque, New Mexico 87112, (505)299-1719.

Ham radio is a quiet hobby, little known beyond its own warm circle, but persistent, and limited to no one nation. Oscar Olson was rather like that himself. Born in Sweden on December 1, 1897, he was transported at the age of seven by ship, train, and finally horse-and-buggy to a homestead near Stenen, Saskatchewan. There he grew to young manhood, working on his father's farm and exploring, in his free time, the scientific marvels of a dawning age. For forty years he was a ham operator. He left behind a stack of yellow radiograms and logbooks dating back to the 1920s. To browse through them is to recapture the history of the humble community in which he spent his life.

In 1926, when Oscar was formally licensed as a ham operator, radio was in its infancy. Enthusiastic amateurs were building their own crystal sets, straining breathless to hear through the crackling static of headphones, undaunted by the envious jeers of less-skilled neighbors.

What goes into the making of the 300,000 licensed amateurs of the North American continent? They are ordinary men and women who patiently learn Morse code, who sit for endless hours fiddling with dials, sorting out beep-beeps from every country in the world, discussing reception, frequencies, trivialities hour after hour, day after day, week after week. Suddenly, perhaps, one may leap into the spotlight of public acclaim at a time of national emergency like a flood or a cyclone. Most live and die "unwept, unhonored, and unsung." What starts them on their dedicated path? What spell holds them to it in spite of daily tedium?

Of course no two hams are identical. Yet surely all of them must share one common trait – the love of tinkering. Most of them originally construct at least a part of the equipment with which they work. In the early days that we are remembering just now, perhaps they constructed all of it.

Oscar belonged to a type that is disappearing in this day of standardized technical education. He was a self-taught enthusiast, a man who developed a natural skill without the help of formal education.

Today one turns the leaves of those logbooks that record the daily radio contacts of forty years, and marvels at the neat script which would put to shame most high school students of our own day. One gazes at the painstaking sketches of mechanical apparatus that apparently interested him – sketches that, to an untrained eye at least, look like the work of a professional draftsman. For many years Oscar kept a radio sales and repair shop in Sturgis. He also farmed with his brothers Andrew and Eric. Oscar was the one who repaired things – radios, farm machinery, whatever in the neighborhood broke down. The boy who put his clocks back together never gave up until he found what kept the radio or the tractor from functioning.

Oscar is survived by a wife and four sons. His ham equipment sits in his Sturgis home, dismantled now, awaiting the time that one of the boys will, perhaps, establish a permanent home and take up his father's hobby.

During the two and a half years after the stroke that ended his days at radio and key, who knows what Oscar thought or what he remembered? But we remember him – and the thousands like him who put their bits of scrap together when the country was young, and started, for good or ill, man's conquest of the airwaves. Let's pause a moment now, and toast them all. Ladies and gentlemen, I give you the pioneer hams of North America. May God bless those who still live, and the memory of those who, like Oscar Olson, have passed beyond the reach of key and code!

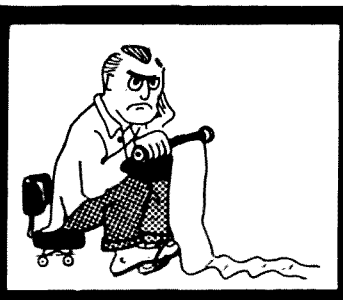
Hamfests and Other Happy Occasions



Oklahoma

The annual hamfest at Lake Texoma Lodge on Lake Texoma, near Kingston, Oklahoma will be held this year November 13, 14, and 15th.

All the programs will be indoors

California

The 9th Annual Greater Bay Area Hamfest will be held at the Edgewater Hotel in Oakland, California on October 18—19th of this year. For the 10,000 amateurs in the San Francisco

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

The FCC jammed through its contribution to inflation, the rule that increases the cost of an amateur license from $4 to $9 for five years. I suppose this isn't so bad in the context of $2 movies (how many of you can remember those Saturday afternoon matinees with two main features, one western, two serials and six cartoons for 10¢?) and teensy 25¢ ice cream cones.

The argument against raising the ham tax was that we need to turn every stone we can to get more hams, and anything that could possibly slow down the entry or continuance of amateurs should be avoided. Like more than doubling the tax. It probably wouldn't have bothered many of us so much if there had been a raise in the tax on the commercial licenses, the permits to make money.

At any rate, starting immediately you will have to pony up $9 and there doesn't seem to be much to be done about it. A good lobbyist for amateur radio in Washington undoubtedly could have stopped this, but we don't have a good lobbyist in Washington, only a part time unpaid cheapskate who doesn't even have the fare to get to Washington half of the time. You got what you paid for.

ARRL National

Newington hated it, but they grudgingly permitted 73 to exhibit at the Boston ARRL National this time. Last time they turned thumbs down and 73 was not permitted to have a booth. They did remain adamant that none of the 73 staff be permitted on the program so (unless some special arrangements can be made) you will miss hearing about FM and repeaters from Ken and miss seeing my slides of King Hussein and Jordan. Too bad about that, but that's the way it is with ham politics.

W2NSD/1 Nightly Sked (wife permitting)

Last month I set up a schedule on 14.300 MHz nightly at 0200Z, plus whatever time after that it takes me to remember the schedule, and providing my wife hasn't yanked me out to the movies or something. After a few nights on 14.300, I want to publicly express my sympathy with the 141,000 General and Conditional licensees who are stranded in that unbelievably crowded band segment. Normally I operate down around 14.210 or so, and while there is QRM there most of the time, it is usually on the order of S8 or so. On 14.3 the QRM is seldom below +10 over 9, and frequently squashes any signal below +30.

At first I was going to set up shop on 14.280, but after a couple nights of trial I gave up the idea of trying to work in between all of the nets that are set up there. 14.300 seemed better in that at least there did not seem to be any organized activities there.

Try me on 14.300 if you have any traffic. I have a big signal and will try and pave a way for you to get through. I'm looking for any information that might be of interest for the news pages, things like DX news, emergencies, medicine to save babies, or whatever you think might be of good general interest. Please do not call in about subscriptions, advertisements, JY1 cards, or anything commercial.

Anecdota Wanted

Jean Shepherd K2ORS called the other day to say that he has started work on a book about amateur radio aimed at the youngsters. He would like to hear from any amateur who has had an unusual experience that might be worth including in the book. Have you been involved in anything unusual or exciting which might be worthy of inclusion in a book about our hobby? Send the particulars to us to pass on to Shep. Send the stories to Shep, c/o 73 Magazine, Peterborough, N.H. 03458.

Mideast Perspective

Though I try to keep up on worldwide current events, and probably do more than most people, I found myself woefully short on anything more than generalities when I went to Jordan. The impression I had from the usual flow of Mideast news in the U.S. was that Israel had made just about every concession possible in an effort to get the fiery and intransigent Arab leaders to sit down and try to work out a peace arrangement.

While I was in Jordan I naturally heard quite a bit of the other side of the story. The rather extensive report by Newsweek, a magazine that I have come to trust down through the years, was strikingly similar to the evaluation of the situation I had been hearing in Jordan and this cast some doubt in my mind about the objectivity of

Foldover tower prepaid, $199.95: New Mosley Classic 33 and Demo Ham-M Rotor, $198.00: New Gonset GSB 201 MklV Linear, 2000 Watts, ($495.00), CASH PRICE $349.00: New Swan 350C, ($420.00), CASH PRICE $329.00: Reconditioned Equipment: L4-B, $549.00: 75A-4, $319.00: and there will be entertainment for all. There will be the customary program of technical discussions, swap and shop, and there will be display tables provided free if you are registered at the lodge.

New Jersey

The South Jersey Radio Association will hold its 22nd annual hamfest on Sunday, September 13th at Molia Farms, off Route 47 at Malaga Lake, Malaga, N.J. 1000–1700 hours, EDST Talk-in and hidden station hunt on 2, 6, and 10 meters. Registration is free but modest fee for prize-drawing tickets. Swap shop, swimming, children's games, snack bar and lots of contacts. Additional detail from Jack Koch K2MZP, 1529 Dogwood Dr., Cherry Hill, N.J. 08034, 609–429–2642.

New York

The annual Syracuse VHF Roundup will be held at the Three Rivers Inn, Route 57, 10 miles north of Syracuse, N.Y., Saturday, October 10. Reservations and information from Charles Sellwood, W2RHQ, 902 1st North Street, Syracuse, New York 13208.

Illinois

The Peoria Area Amateur Radio Club, Inc. will hold it's 13th annual hamfest Sunday, September 20, 1970 at Exposition Gardens (same place as last year), located on the northwest edge of Peoria, Illinois. Lunch will be available. There will be plenty of activities for the entire family, beginning with the campsite opening the preceding evening. Free coffee and donuts from 9:00 to 9:30 a.m. CDT. Free swap section, parking, contests, and cartoons for the kiddies. Advance registration $1.50, ($2 at the gate). For further details and advance registration, write Ferrel Lytle W9DHE, 419 Stonegate Road, Peoria, IL 61614.

Bay Area, this promises to be the biggest hamfest ever.

With the interest that amateurs have displayed in previous years in mind, this year's hamfest will emphasize quality presentations of seminars and exhibits. In 1969 there were more than 1000 amateurs at the hamfest and visiting the exhibits. It is expected that the attendance this year, moving closer to the center of the amateur population in the Bay Area, will surpass this mark.

Illinois

The Chiburban Radio Mobileers announce the 3rd annual 160 meter reunion, Sunday, September 20, 1970 at the Joliet Beach Club, Joliet, Illinois.

There is no admission charge, and no formal activities are planned. The reunion is a chance to get together with other enthusiasts to discuss equipment, operations, noise problems, DX, use of frequencies, etc. Last year's mobile efficiency contest evoked so much discussion that it may be repeated with revised rules. Slides and snapshots of various 160 layouts will be shown.

The Joliet Beach Club is located on Rowell Avenue, immediately adjacent to Interstate Route 80. For those who wish to stay over, there is a Joliet Holidy Inn, and a Howard Johnson motel nearby. Talk-in on 1810 kHz.

Ohio

The 33rd annual STAG hamfest sponsored by the Greater Cincinnati Amateur Radio Association will be held on Sunday, September 27, 1970, at Stricker's Grove on Compton Road, Mt. Healthy, Cincinnati, OH.

The "Cincy" STAG hamfests have grown in popularity each year; last year's attendance was over 2300 hams.

Long-Range Planning for a "Biggie"

If plans continue on course, the next SAROC Las Vegas convention should top all existing ham convention records. Leonard Norman (W7PBV), chairman for the event, says that two charter flights are being negotiated with Chicago- and New York-based airlines. The deal, says Norman, will allow hams near these big cities to come to SAROC at a package price. For less than "normal airline fare," the package will include a champagne flight, transportation to and from the Flamingo Hotel (where SAROC's being staged), tickets to a major stage show, registration and drawing tickets, the annual SAROC breakfast banquest, cocktail parties, seminars, a complimentary casino "free money" packet, and heaven knows what else.

The way things look now, you'll be able to charge the whole thing on your regular credit card (Carte Blanche, American Express, Diners Club, etc.). As far as I can tell, there's just one big hitch: There will be only one charter plane leaving from Chicago and one leaving from New York. Those who make reservations early can be accommodated, but if you wait, you'll end up being left out. To be safe, better drop a card to Leonard Norman now and let him know if you plan to be on either of the two flights. (His address is Box 73, Boulder City NV 89109.)

SAROC is always a big thing for everyone, but this next one should rank particularly high with the FM crowd.

For one thing, both Chicago and New York are FM strongholds, so the number of FM'ers on the flights will probably be disproportionately high. For another, the affair at SAROC will be FM's fourth annual national convention.

The tentative FM schedule so far includes as speakers: Wayne Green of 73 Magazine (and me, of course); Dr. Phil Dater (WA5JDZ), key man behind the chain of interconnected New Mexico repeaters; Art Housholder (K9TRG), general manager of Spectronics, Incorporated; Pat Devlin (K5BPS), from Tulsa Repeater fame; and Gary Hendrickson, renowed author and principal of the Baltimore repeater.

On the regular SAROC agenda (non-FM), the scheduling of speakers is still under way, but I'm sure the lineup will include Wayne Green's slide presentation of his recent visit with King Hussein in Jordan.

At any rate, the Flamingo is making some advance preparations. It has blocked off 600 rooms for the exclusive use of SAROC attendees, who qualify for the special $12 room rate. The advance registration price for those not making the charter flights is $14.50 per person, which includes – among lots of other things – a late show at the Flamingo, a couple of drinks (at Flamingo or Desert Inn), breakfast, cocktail parties, etc.

Repeater Cliques

It's still a little early to call it a trend, but more and more reports are coming in that repeaters are turning "unfriendly." More open repeaters are turning inward, closing to "outsiders"; more member-supported groups are hiking their dues to lock out would-be users.

These are bad signs indeed. Most of the "old salt" FM'ers remember the first couple of years of repeater growth, where the situation was reversed. Repeater owners wanted to encourage as much activity as they could. Then, AM "neighbors," threatened by the big loud band-dominating machines, fought by jamming, boycotting, maligning, and just about every other tactic they could think of.

Repeaters are an accepted part of our way of life, now, but a lot of the "good guys" of yesterday are turning into the "heavies" of today with the techniques some of them are adopting to inhibit further development.

The first step is an innocent one: A club forms for the purpose of providing a means of support for a repeater. The club will usually include a few officers with enough technical talent to keep a repeater percolating and enough members to keep the thing financed adequately.

Alford Memorial Radio Club

3271 White's Mill Road
Decatur, Georgia, 30032

July 13, 1970

Dear OM,

Your application for membership was considered at the last regular meeting of the Alford Memorial Radio Club. Unfortunately, no sponsor was present to support your petition and the members present therefore could not act favorably on your application. Should you desire to re-apply for membership at a later time, please be sure a sponsor is present to support your petition. In addition, please include a short sketch of your activities as a Radio Amateur and state the reasons you would like to join this repeater organization.

We will be pleased to reconsider your application at a later time if you so desire.

Yours very truly,

Taylor F. Whitmire, Sect/Treasurer
Alford Memorial Radio Club

A bam in Decatur, Georgia wanted to operate through the local "open" repeater, operated by the Alford Memorial Radio Club. This letter to him from the club secretary speaks for itself.

The next step is the dangerous one: setting up two price lists that serve to factionalize the repeater users. This sets up an "inner group" of a few individuals who think of themselves as an elite caste.

A concerned amateur in one of the biggest cities in Georgia called me recently to tell of a repeater there that will not accept new members. He said transient use of the repeater was discouraged, full membership in the repeater organization was closed, and that operation through the repeater resulted in boycotts or insults. Yet, he said the repeater is referred to (by its management) as being "open," it is set up on nationally accepted channels, and it does not require subaudible continuous tone (PL) for activation.

An amateur in New England called with essentially the same complaint about another repeater. And my letter file includes numerous such reports. It is clear that someone should do something before the situation gets out of hand.

I don't think for a moment that these cases are all one-sided. In some cases, certain individuals are being discouraged because they do not respect the local traditions of repeater use. In others, individuals are discouraged for long-windedness, excessive activation of the repeater, or simply bad operating habits.

However, if the locked-out individuals begin to grow in number; if the repeater takes on the aspect of a "closed" setup; if transients are ignored or discouraged; or if PL is put to use to limit the number of users – then it's time for some giving on the part of the repeater groups.

I have always held that closed repeaters do not belong on national repeater frequencies. A closed repeater on either the .34–94 or .34–.76 pair is an open invitation to unrestricted use by anyone who buys an FM unit. Let the closed repeaters function, but let them function where they do not impose on the rights of others. The simple fact that most ham FM units come equipped with crystals for .34 and .94 makes those frequencies "public," and it is certainly within the rights of a newcoming FM'er to operate using the crystals that came with his rig.

Also, a closed repeater using .34, .76, or .94 prevents the establishment of an open repeater in the area on those channels. The result is that if an open repeater is to evolve, it is forced to happen on a nonstandard frequency pair – the only alternatives being a direct conflict for the national channel or no open repeater at all.

Repeater organizations are necessary, of course, and dues are necessary if the repeater is to be maintained. But all of us should remember that amateur radio is a fraternity traditionally characterized by the "ham spirit." If we let factions and cliques gain a solid foothold in an area as important as FM repeaters, our now-excellent reputation will be threatened in the eyes of the rest of the amateur world. And our image of friendliness and fellowship will decay and crumble.

New Subscription Rates?

YOU BET

With this issue of 73 we close out our first ten years of publication. In an era of unprecedented inflation we have done well, we think, to keep our subscription rates as low as we have. We started out at 37¢ a copy, went to 40¢ when the newsstands protested the odd figure, then went to 50¢, 75¢, and finally a dollar. Our subscription rate started at $1 a year, and went to $12 for three years back in 1966.

If congress and the administration would try and cut expenses down we suspect that the inflation would stop. As long as they keep the Bureau of Engraving busy three shifts a day printing more money, we can't have anything except inflation, and (as has been proved rather clearly) curbing consumer credit only makes the situation worse by adding a recession to the inflation.

Suffice it to say, we must inch our subscription rates up a little bit more just to stay in one place. The new subscription rates will take effect with the next published issue of 73, thus giving you time to repent over dawdling on sending in your money.

Leaky Lines

1 DANIEL LANE, KINNELON NJ 07405

Isn't it time someone did something to relieve the problem of unrestricted use of the entire HF spectrum on such activities as Field Day? The 1970 edition of this annual exercise presented a perfect example of the utter futility of any effort to utilize the bands for any other purpose. From the low CW end to the top of the phone portions of each band there was bedlam. It was just about impossible to get through the crud without being interrupted by FD participants looking for extra contest points.

There is nothing wrong with contests, if you happen to like them, SO LONG AS THEY DO NOT PREEMPT THE ENTIRE AMATEUR SPECTRUM. There seems no logical reason why some portion of each band should not be inviolably secured from contest activity, so that normal use of the bands for standard operation and ordinary ham activity may continue unimpaired.

The ultimate in tactlessness, rudeness, and plain old-fashioned crust was noted when both parties on a phone patch were interrupted and requested for a Field Day contact by some eager beaver in the Fourth District. I would not have believed it possible if I had not heard it myself. The most ridiculous part was, this was an overseas patch to South America, dealing with some missing persons in the earthquake sector of Peru. To say that the operators of the patch were miffed would be the rankest understatement.

Nobody is compelled to participate in any activity he does not fancy. But there has developed a certain breed in recent years, who do not try to understand this. These characters think they have a perfect right to interpose their unwanted presence at will; to ask for reports, audio checks, S-meter readings, opinions about . . . "this microphone I just bought, and what do you think of the quality, Old Man?" This goes on all the time, ad nauseum, without a single thought whether it is right or wrong. That he may be an unwelcome intruder never enters this type's mind, it seems.

And when these people get what they deserve – either total disregard, polite refusal, or an out-and-out reading of the riot act – they feel that they are being sorely put upon. In this scribe's humble view, any imbecile who would interrupt an overseas phone patch to request a contest contact ought to get his head handed to him, or ought to be rewarded with a good, swift kick in his "sitzfleischl."

It would be extremely helpful if certain segments would be declared out of bounds by sponsoring groups of contests, so that participants would understand clearly that any contest activity therein would be proscribed. In the regularly scheduled CD parties, a very small segment of each band is recommended, and to the best of my knowledge, very few noncontesters are inconvenienced by these popular contests. The various other contests which have not yet seen fit to emulate this example could certainly profit by doing so.

* * *

In recent months, on 3997 kHz, a powerful AM station has been operating every evening, starting at 2330 GMT. This is the recently established RSA, the outgoing service of the South African Broadcasting Corporation, in Johannesburg. During the course of their broadcasts, it has been next to impossible to use the adjacent frequencies, due to their big signal. On my receiver they are usually about 30 to 40 dB over S9.

By fortunate happenstance, I happened to hear them playing a recording of one of my songs, and I seized the opportunity to write and thank them for the performance, and incidentally to get in some licks about the interference to amateur operations. They sent me a prompt reply, consisting of a Manila envelope about an inch thick, containing, among other things, their broadcast schedule, times, and frequencies.

There is absolutely no mention of 3997. Their frequencies are announced as 9705, 9695, and 5980. There is no way by which these can be beat together or combined to produce a beat of 3997. However, in a compendium of AM stations of the world, issued by our own government, and available at the Printing Office, the frequency is mentioned as being allocated to RSA.

So I sat down and wrote again. I explained that it would be extremely unlikely that they would garner any sizable group of SWLs on that frequency, since it is occupied solely by amateurs, with whom, unfortunately, they were interfering. Their 250 kW, I added, was being wasted on this particular segment, and might they not reconsider and curtail the use of 3997 in the evenings. I closed the letter with a polite request for further information, if any, and for

AN INTEGRATED CIRCUIT CW ID GENERATOR

P. J. Ferrell W7PUG
6021 S. 119th St.
Seattle WA 98178

A project to develop an automatic, solid-state CW ID generator was recently initiated by members of the Seattle repeater group. Although there have been a number of recent articles concerning such devices,[1-2-3-4] our starting point was the FM Magazine article by Woore.[2] The outcome of this project must be classified as an engineering overkill. The resulting CW identification generator features a clocked character generator (for flawless CW with variable speed), inexpensive RTL integrated circuitry, and a computer-designed diode read-only memory matrix. Also included are "pulse" starting, a discrete "hold" voltage available during ID execution, and a continuously adjustable keying speed (from far too slow to far too fast). Not only are these generators ideal for repeater identification, but they may be used to identify any amateur station such as RTTY, ATV, etc.

The block diagram in Fig. 1 shows the major divisions of the ID generator. Many excellent articles covering RTL logic design

have appeared in amateur literature[5-6] and the reader is referred to them for background material.

Program Counter and Start/Stop Flip-Flop

This six-stage ripple counter consists of three dual JK flip-flips. The first five cascaded stages are the program counter and count from 0 to 31. The last stage is employed as the start/stop flip-flop. Each stage of a ripple counter is arranged to toggle (change state) on the output of the preceding stage. A five-stage program counter has 32 distinct stages (2^5=32). (number 32) resets or clears the first five stages, but toggles the start/stop flip-flop to the "stop" or set position, thereby halting the character generator.

A positive pulse into the "preclear" input of FF6 clears the halt and allows the character generator to run, thereby initiating a cycle of operation. A five-stage program counter was chosen since virtually all amateur calls can be encoded in 32 characters worth of dots, dashes, and blanks. RTL JK flip-flops are adversely affected by capacitive output loads, and

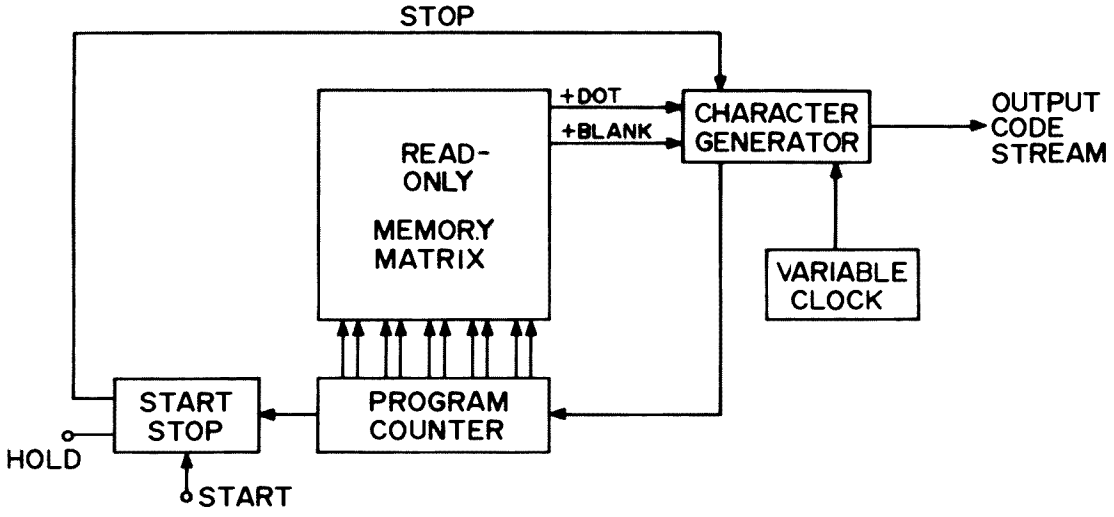

Fig. 1. CW ID generator block diagram.

When arranged as shown in Fig. 2, the program counter advances under the control of gate G1 which derives its input from the character generator. Each dot, dash, or blank character advances the program counter by one count. The last character will not toggle reliably if the capacitance is too high. This fact precludes the use of silicon diodes in the *and* portion of the diode memory.

If the program counter output lines were buffered (isolated from the flip-flops

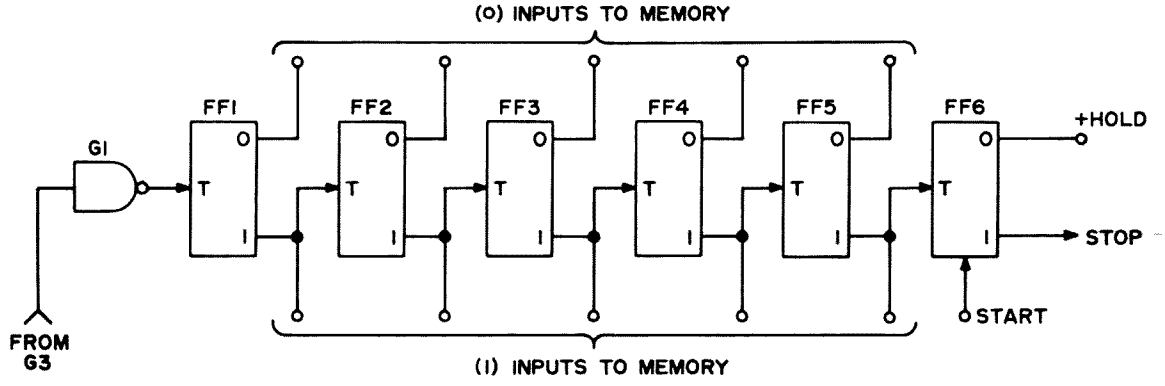

Fig. 2. Program counter.

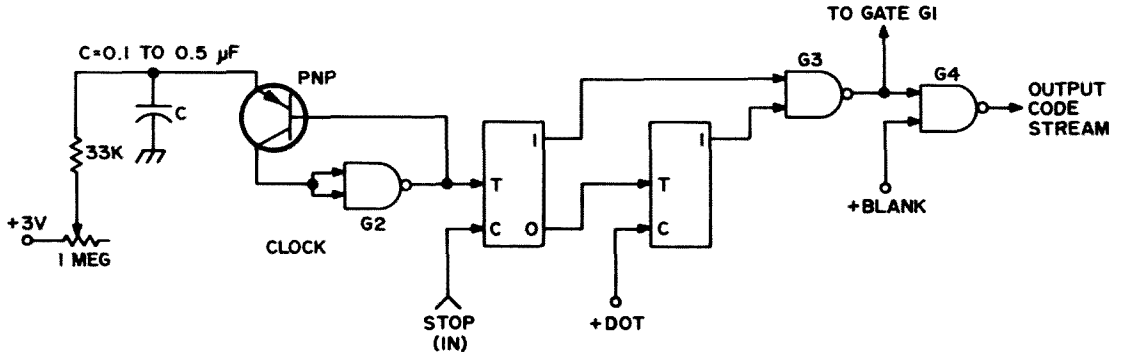

Fig. 3. Clock and character generator.

with gates or inverters), then any type of diode could be used in any memory position; but germanium diodes have very low capacitance and may be connected directly to the flip-flop outputs, thereby saving the cost of 10 buffer stages.

Variable Speed Clock

The clock circuit must deliver a negative-going pulse with leading edge of less than a microsecond duration in order to toggle an RTL JK flip-flop. The pulse repetition rate should be variable to permit choice of code speed. The circuit is shown in Fig. 3 with a PNP silicon transistor paired with gate G2. The net effect is a PNPN switch. Capacitor C charges to about 2V and then discharges through the gate with a leading edge which is very abrupt.

Nearly any of the new PNP silicon transistors will work in this circuit. The minimum value for R is about 33 kΩ else sufficient current is available to hold the switch in conduction (just like a neon relaxation oscillator). For R much above 1 MΩ insufficient current is available to initiate the regenerative "snap" action. Values of R between these limits work well.

Character Generator

The electronic generation of Morse code requires the creation of dots, spaces, dashes, and blanks which have a precisely specified relative length. The dot and space are each of one unit duration, while the dash and blank are each of three units duration.

An extremely clever character generator was borrowed from the Micro-Ultimatic Keyer[7] and forms the heart of the ID generator. The character generator consists of two JK flip-flops (FF7 and FF8) and gates G3 and G4 as shown in Fig. 3. A positive (stop) voltage on terminal C of FF7 holds it in the clear state, thereby stopping the character generator. If the stop voltage is removed, the character generator toggles in such a manner as to produce a string of dashes at the output of gate G4. If a positive (+DOT) voltage on terminal C of FF8 changes the string of dashes into a string of dots. A dash (or blank) requires four clock pulse intervals while a dot requires two. Gates G1 and G4 each invert the output of gate G3.

The output of gate G1 must be either a dot or dash character (never a blank), and is used to advance the program counter at the end of each character. The second input to gate G4 will blank out the output code stream, and is used to produce a blank character. If a blank is required, then a positive "+BLANK" input from the diode memory causes the dash generated by the character generator to be blanked

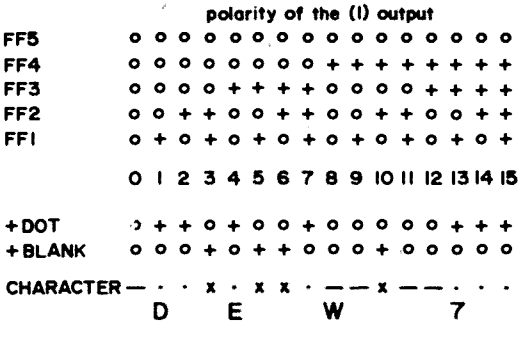

Fig. 4. Diode memory inputs and outputs.

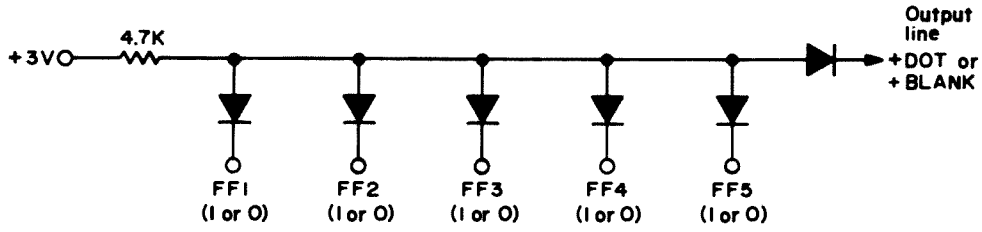

Fig. 5. Diode decoder for program counter.

out – which results in the transmission of a blank character.

Thus, the role of the diode read-only memory matrix is to provide just that sequence of +DOT and +BLANK inputs to the character generator which results in the transmission of the desired code stream. Gate G4 is the output with a plus representing "key down" and a zero representing "key up."

Diode Read-Only Memory Matrix

This is the hard part! Each desired code stream requires a distinct and different read-only memory design. A +DOT voltage must be produced by the diode memory for each program counter state that corresponds to a dot in the desired code stream, and a +BLANK is required for each blank character. An example is presented in Fig. 4.

i.e. if neither a +DOT nor a +BLANK occurs, a dash results. Each of the 32 program counter states must be accounted for since they all appear on each ID execute cycle.

Figure 5 shows the method for decoding the program counter. The five terminals marked FF1 through FF5 are connected to either the **1** or **0** side of the respective flip-flop. If *any* of the five connections is low, then the whole common line is low. The only time the common line can be high is when all five input connections are high. For any given connection, this will occur exactly once during each program counter cycle. This type of diode decoder is often called an *and* gate since it has a high output only when all inputs are high.

Because of the diode output from the common line, these decoders may be paralleled to obtain the required +DOT and

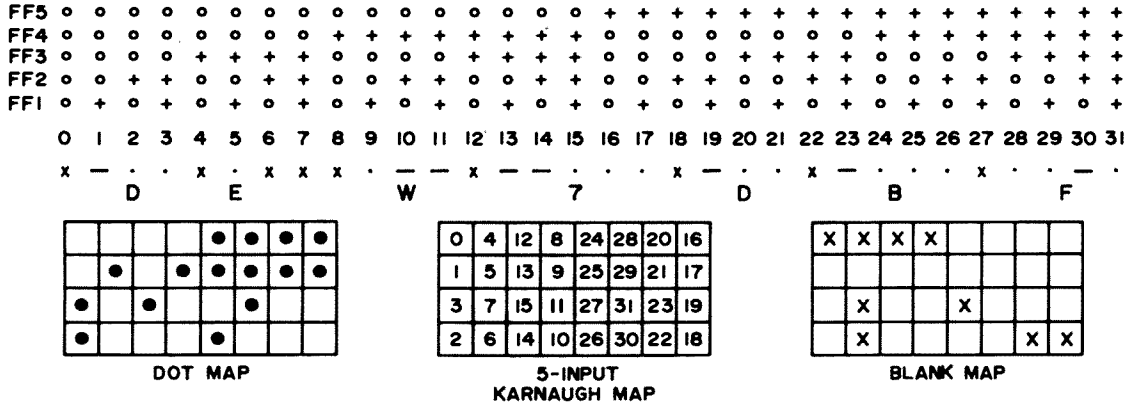

Fig. 6. Using the Karnaugh map.

Suppose that the first letters of the desired code stream were "DE (blank, blank)W7". The program counter states are shown corresponding to the required outputs from the diode memory matrix. A dash is seen to be the "default" condition; +BLANK functions. This paralleling is often referred to as an *or* gate since *any* high input results in a high output.

In the example of Fig. 6, the desired code stream has 15 dots and 9 blanks. If we employ a separate diode decoder for

each one, then a total of 24 decoders would be required: 15 would be paralleled to give the +DOT signal and the remaining 9 would be paralleled to provide the +BLANK signal. Each decoder requires 6 diodes for a grand total of 144 diodes to build a straightforward read-only memory using this technique.

Fortunately for us, the English philosopher George Boole published his *Investigation of the Laws of Thought*, in which he resolved the ambiguity of the words *and* and *or* by means of a kind of algebra. In 1938, eighty-four years later, Prof. D. E. Shannon (the *Information Theory Shannon*) put Boole's algebra or Boolean Algebra to use in the *Symbolic Analysis of Relay and Switching Circuits*. This classic paper has revolutionized switching design, and has led to the development of minimization techniques which can dramatically reduce the diode count of our ready-only memory. The details of these methods and the underlying theory are beyond the scope of this article, but for those who are fascinated by this stuff, standard texts are available which will quickly dispel the aura of "black magic" that seems to surround this area.[8]

For our purpose, a graphical reduction technique known as a *Karnaugh map* will be employed. Figure 6 illustrates the process for the code stream *DE W7DBF*. The polarity of the **1** output levels of flip-flops FF1 through FF5 are shown as the program counter steps from **0** (all FFs clear) to state 31 (all FFs set). The sample code stream begins with a blank and has three blanks separating the **DE** from the **W**

A Karnaugh map organization of program counter states is presented, flanked on the left by the DOT map and on the right by the BLANK map for the desired code stream. Reduction is accomplished by "folding" the map about any of the dividing lines and pairing the marks (dots or blanks) which overlap. For example, folding the DOT map about the vertical centerline pairs dot 5 with dot 21, and dot 9 with dot 25, and dot 15 with dot 31.

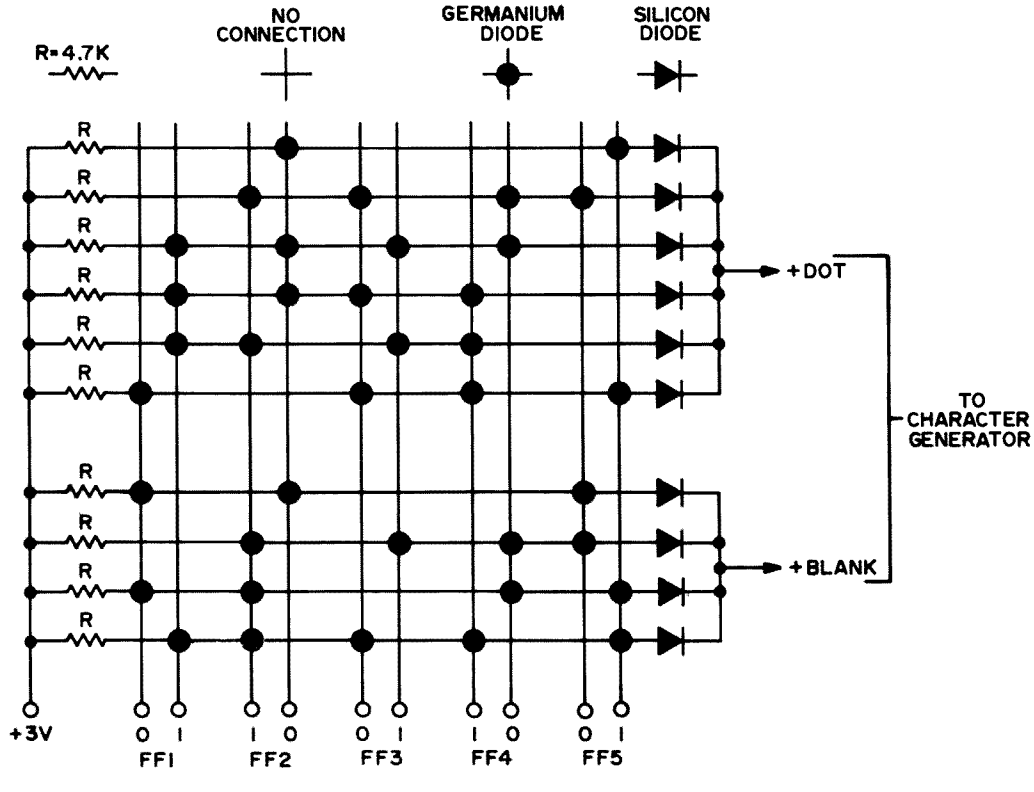

Fig. 7. Diode read-only memory matrix for "DE W7DBF."

Successive pairing, then pairing pairs, etc. allows a reduction from the original 144 diodes to a total of 48 diodes arranged as shown in Fig. 7. Note that in Fig. 7, the **0/1** flip-flop lines are reversed for FF2 and

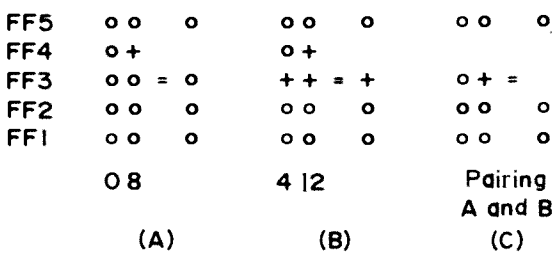

Fig. 8. Actual reduction procedure.

FF4. This reversal materially simplifies printed circuit construction.

As an example of pairing, consider the blanks in positions 0, 4, 8, and 12 of the BLANK map of Fig. 6. If the map is folded about the second vertical line (the one separating positions 4 and 12), then blank 4 pairs with blank 12, and blank 0 pairs with blank 8. If we fold again, then all four blanks coincide

is illustrated in Fig. 8. In part A, the program counter states for positions 0 and 8 are compared. They differ in exactly one FF position (FF4) as all pairs must. A single diode decoder of the type shown in Fig. 5 could get both blanks simply by neglecting to connect to FF4. It even saves one *and* diode.

Part B of Fig. 8 presents the same comparison for blank 4 and blank 12, and again they differ only in FF4. In part C, a comparison of the 0/8 with the 4/12 pairs shows that these differ only in FF3. Thus, if a three-input diode decoder of the type presented in Fig. 5 were connected to FF1 (**0**), FF2 (**0**), and FF5 (**0**), it would give a +BLANK for all four desired program counter states (0, 4, 8, and 12). Without this reduction, 24 diodes (six for each blank) would have been required rather than the four actually required. This diode decoder may be found in Fig. 7 as the first line in the +BLANK group.

The foregoing example illustrates the use of a Karnaugh map. The states which

map, and then the actual reduction is performed as in Fig. 8. It should be noted that some states will not pair at all, such as blank 27 in Fig. 6. To pick up this blank, a full five-input diode decoder is required. From Fig. 6, we see that for blank 27, the program counter is in state "++0++" and the resulting diode decoder can be found in Fig. 7 as the bottom diode line.

The rule when pairing states is that the two program counter states can differ in exactly one flip-flop position. All other positions must agree, including any omitted connections as in Fig. 8, part C. If there is disagreement in more than one FF position, then these two states do not pair.

After completing the reduction process, check to make sure that every necessary state has been covered at least once by one of the final decoders; otherwise, you may be surprised at the resulting code stream. This type of calculation, once understood, is not particularly difficult, but it certainly is tedious and has lots of room for errors. Slight changes in the desired code stream (even position) can have a huge impact on the diode count.

For example, the diode count for the code stream in Fig. 6 is 48. If just the *DE* is slid one count to the right, a new code stream is formed which starts with two blanks, and has two blanks between the *DE* and *W*. The diode count for this new stream is 55. If this new stream is shifted two positions to the left, so that the two leading blanks become trailing blanks, then the diode count becomes 85. These effects are unpredictable, and for complete optimization each code-stream version must be reduced separately, and the results compared. This greatly increases the already great tedium of such calculations.

Computer Optimization

In order to minimize the pain of diode memory design, the task was subcontracted to a digital computer. The Seattle repeater group is extremely fortunate in having remote access to the University of Washington Computer Center's Burroughs B5500 computer, one of the nicest hardware/software systems ever put together. The resulting program in extended ALGOL accepts the desired code stream (in dots, dashes and blanks) as an input and performs a complete Boolean reduction for both +DOT and +BLANK diode decoders.

If the specified code stream is less than 32 characters (more than 32 characters are not allowed), then the computer assigns the necessary trailing blanks and performs

```

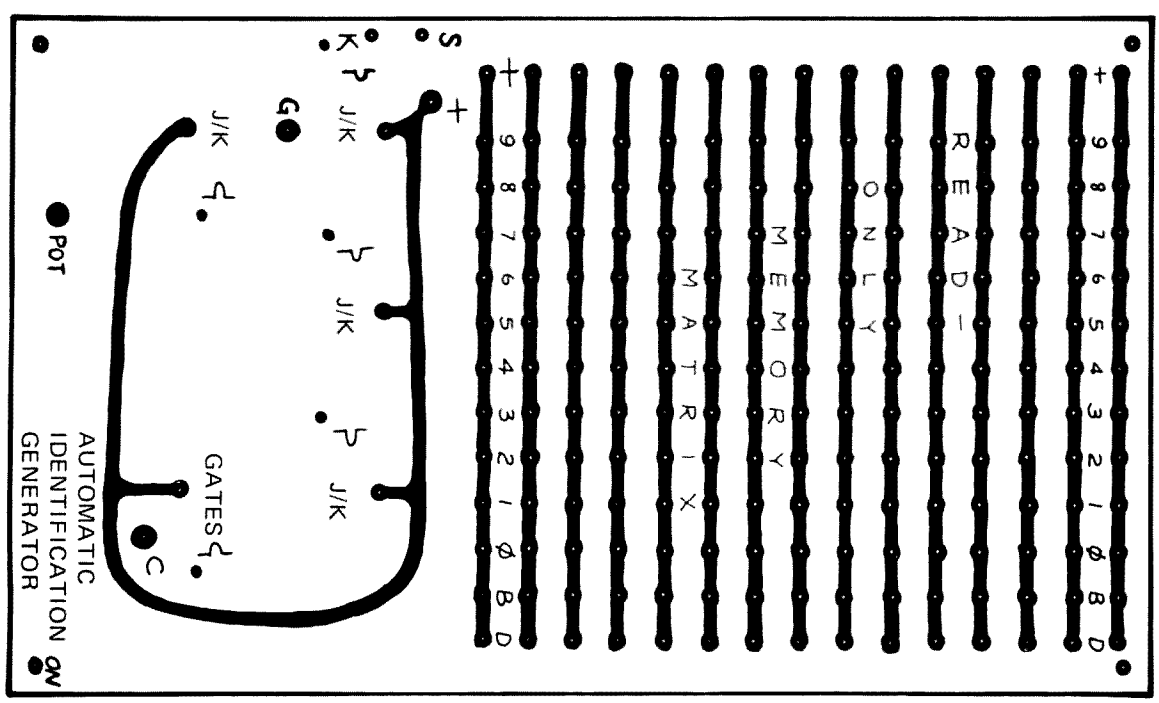
Fig. 9. Computer printout.

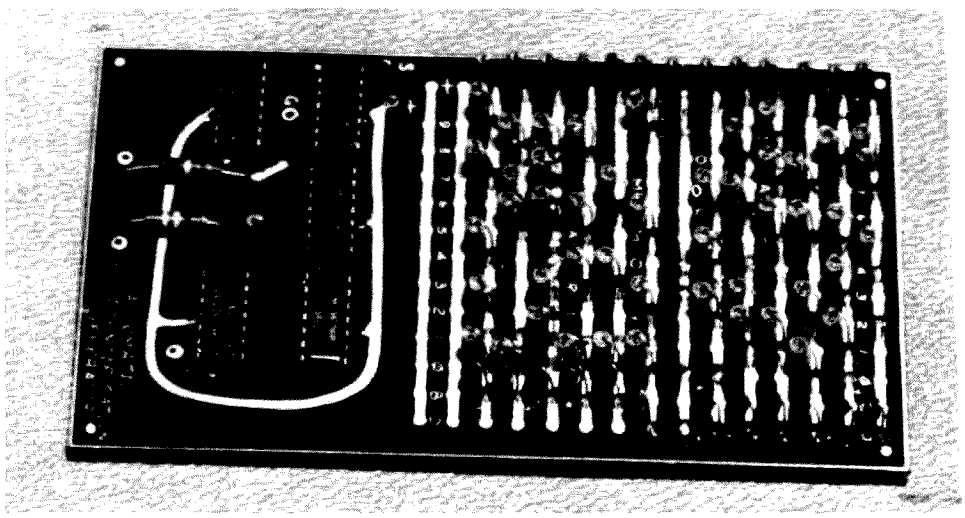


the required reductions, and repeats the process for each shift of the code stream until all the trailing blanks have become leading blanks. The code stream version having the smallest diode count is printed out along with diode and resistor counts and an actual map of the entire diode read-only memory matrix. Examples of the digital computer printout are shown in Fig. 9.

Construction

The four dual JK flip-flops are Motorola MC790P (or HEP 572) and the quad 2-input gate is a Motorola MC724P (or HEP 570). Virtually any PNP silicon tran-

Circuit board (bottom).



Circuit board (top).

Fig. 10. Full-size reproductions of PC board.

sistors will function in the clock circuit. A HEP 57 is a good choice. Both germanium and silicon diodes are used in the diode read-only memory. Germanium diodes are employed for the *and* function, since their low junction capacitance will not load the JK flip-flops in the program counter. Either silicon or germanium diodes may be used in the *or* function, with silicon signal diodes preferred since they result in a higher noise margin for the memory. Cheap diodes are available from various solid-state supply houses. Poly Paks features 50 silicon or germanium diodes for $1.

Both sides of 3 x 5 in. double-sided PC board are shown in Fig. 10. A one-sided board was used for the first few models, with a second 3 x 3 in. board used to complete the matrix connections. This "cordwood" construction is a pleasure to look at, but a nightmare to wire up. If a diode goes "west" on a cordwood style generator, it is best to throw it away, since unsoldering about 80 diodes and resistors and then getting things back together is even worse than the initial construction effort. A double-sided epoxy–glass PC board is recommended for the ID generator. An operational generator should be enclosed in a metal box with all leads bypassed for rf. Even VHF/UHF fields have the ability to drive RTL logic circuitry absolutely crazy. Before undertaking the construction of this ID generator, the builder should obtain as many of the referenced ID generator articles[1-2-3-4] as can be found and read them over carefully. The additional background material will amply repay the effort involved.

The Seattle repeater group can supply a moderate number of tinned epoxy–glass circuit boards for this ID generator. The board is not drilled, but assembly instructions and a computer optimized diode map for the circuit board is included. Be certain to specify the desired code stream, keeping in mind the absolute limit of 32 characters (dots, dashes, and blanks). Unit cost is $10, and they may be obtained from the Seattle repeater group, 18235 46th Pl. S., Seattle WA 98188.

Here's what the board looks like when the flatpacks and diode matrix are soldered in. The vertical placement of the diodes helps to keep the size down to this 3 x 5 in. circuit board.

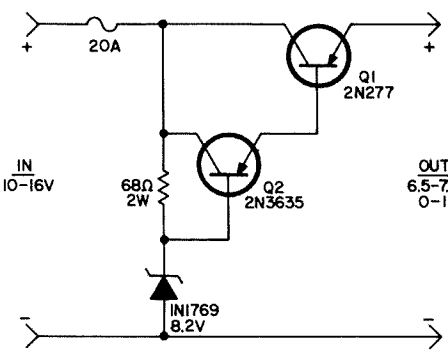
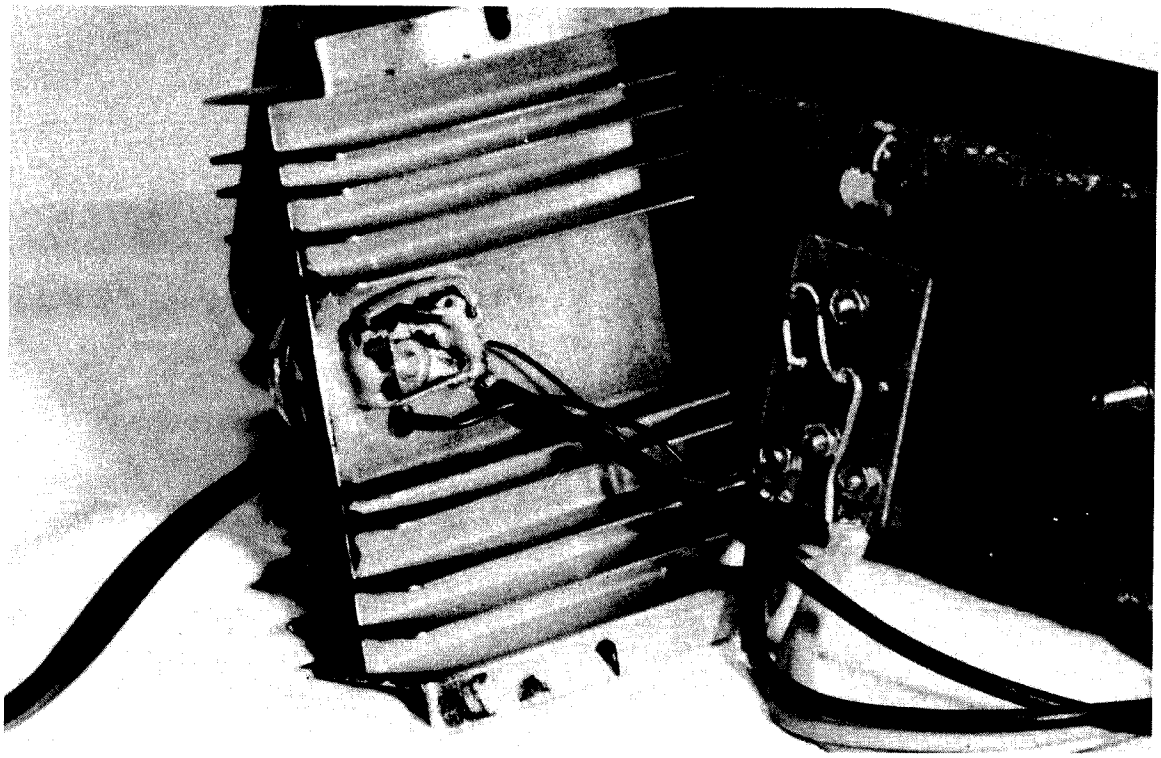
6 volts from 12 volts the Easy way

Thomas J. Warnagiris K3GSY
118 Waupelani Drive
State College PA



Mobile gear designed for 6V batteries is often sold at a bargain price simply because 6V electrical systems are not as common as they once were. I recently bought a 6V transceiver suitable for 2 meters FM. At the time, I had visions of doing a little tinkering to change the internal supply to 12V. Unfortunately, the internal supply turned out to be almost as complicated as the rest of the transceiver. Instead of a little tinkering it was going to be a lot of hard work. One possible alternative was to somehow get 6V from my car's 12V electrical system.

The classic method of using a dropping resistor wouldn't work in this case. Like most transceivers this one required almost ten times as much current while transmitting as it did when receiving. With a dropping resistor this meant providing the proper current and voltage while receiving, then upping the source so I still got 6V when I tried to draw ten times as much current for transmitting.



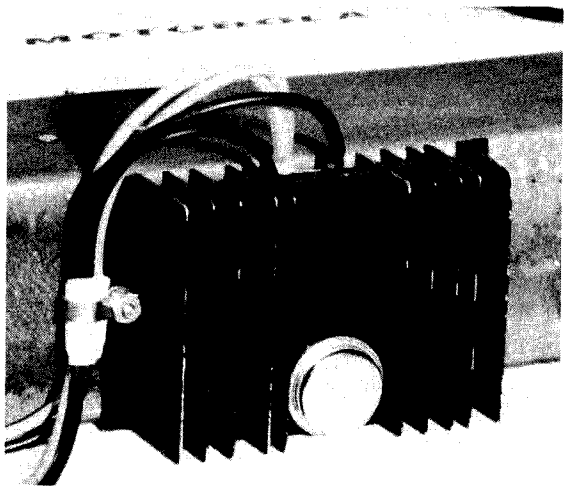
The solution was to build a device that would deliver a constant voltage under all conditions. This device would also have to handle currents of from 1 to 15A and yet be cheap enough to make buying 6V gear still seem attractive. A little investigation pointed to a solid-state regulator as probably the best answer. True, it would be as inefficient as a dropping resistor power-wise, but for my purpose, simplicity and low cost were more important than power efficiency. So with these requirements in mind I came up with the circuit shown in Fig. 1. It worked so well that I thought others with 6V gear and 12V vehicles would like to try it.

Operation

When I switch from transmit to receive, the current to my transceiver jumps from 1.5 to 12A. As this happens, the current to the base of Q1 changes from a few microamps to only a few milliamps due to the current gain of the transistors. The base current for Q1 is drawn from a point at 8.2V; voltage is produced by a zener diode and a 68Ω resistor. The zener diode maintains essentially the same voltage when the current through it changes. So with about 100 mA flowing through the diode, little

happens to the 8.2V when a few milliamps are diverted from the diode to the base of Q1. Q1 and Q2 have only current gain and no voltage gain due to the way they're connected. This means that the 8.2V of the zener appears across the load. Actually, there is a small voltage drop through each

Inside view of the regulator. All components except a zener diode are epoxied to the heatsink. The small fiber glass board holds the zener and acts as a strain relief for the heavy wires.



transistor, and the voltage to the transceiver is about 6.5V.

Parts and Construction

When I first began collecting parts from my regulator I bought a bargain power transistor and a heatsink from a mail order surplus dealer. The rest of the parts I scrounged from my junkbox. Unfortunately, a 2N3635 happened to be the only transistor I had on hand with the right characteristic to drive the power transistor. I say "unfortunately" because a 2N3635 carries a rather high price. Luckily, there's a large group of cheap transistors (2N2147, 2N4314, 2N3613) that will work as well. If you don't use a 2N3536 you'll find that the regulator parts are low cost, easily found items. You can buy everything necessary from any large electronic distributor at a cost of about $6 or less.

The parts you end up with and the space available will determine the exact layout. Placement of parts is not critical, but try to put the regulator in a spot where heat will not be trapped. For best heat removal, mount the regulator on a large metal surface, with the heatsink fins open to the air.

I mounted mine on the back of my transceiver as shown in the photo. This allowed the chassis to carry away most of

Top view of the regulator showing input and output lines. All other circuitry is located under the heatsink.

the excess heat. The 2N3635 and the 2W resistor normally run warm, too, so I epoxied both to the underside of the heatsink. To hold the zener and serve as a strain relief for the heavy wiring, I made a small fiberboard card. The card fit nicely

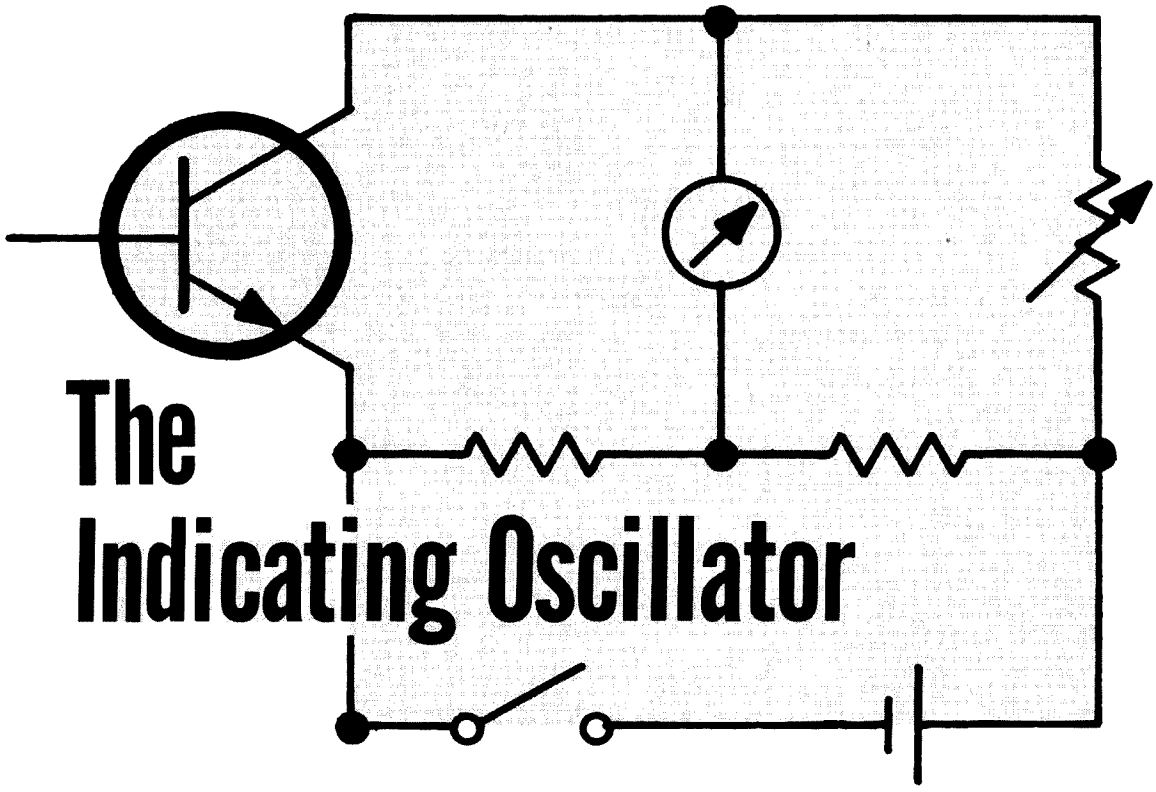
under the center section of the heatsink despite having some of the space taken up by the epoxied parts. From the card I ran 14 AWG stranded wire through a 20A fuse to a plug designed to fit a cigar-lighter socket. With everything except the fuse enclosed by or mounted on the heatsink, the regulator proved to be both compact and rugged.

Checkout and Alignment

When the regulator is completed it will require some simple tests before it's ready for operation. Carefully check all the wiring before connecting it to a 12V supply. Because of the high current involved, a wiring mistake could be dangerous. As a check on the output voltage, connect about a 10Ω 10W resistor to the output and a 12V supply (or car battery) to the input. Measure the voltage across the 10Ω resistor (should be about 7.5V). This will be the output voltage under light load. When the current drain is raised to 15A, the voltage will drop by about a volt. The drop is usually all right since most 6V gear will work from a 6–8V supply. If you feel that the output voltage is too high for your application, change the 8.2V zener diode to a 7.5V diode. This will drop the output voltage by 0.7V.



Comments

Once testing and alignment are completed, the regulator should be in good working order. The output voltage will stay almost constant even if the supply voltage goes as low as 10V or as high as 16V. And currents of 1–15A can be drawn with only a small change in output voltage. I don't recommend applying more than 16V to the regulator or drawing more than 15A through it; such conditions exceed the ratings of the power transistor. Also, don't try to draw maximum current continuously if your heatsink is not capable of dissipating at least 150W. If you don't intend to draw high current or you draw high current intermittently, a smaller heatsink can be used.

The Indicating Oscillator

Relatives of this little gadget have been around a long time! Even the transistorized versions, which usually leave something to be desired. With an FET, however, we are back in business as with tubes, but with many advantages.

The range of this oscillator is fantastic. That is, without any circuit tricks or special handling. The low frequency end was carried down to the 1 MHz in order to cover the lowest ham band. The high end takes care of 250 MHz easily. This can be extended with a little more effort.

Use of a field-effect transistor (FET) allows operation more nearly like the tubes with which we are, perhaps, more familiar. However, we are not tied to the power lines, which alone makes it worthwhile.

A 2N4221 FET was used in this indicating oscillator. Very likely other FETs will work also. The MOSFETs also should be as good, if not better. The new ones with built-in diode protection would be much easier to handle.

Standard banana plugs spaced ¾ in. make ideal bases for the coils. The lower frequency coils are wound on polystyrene forms.

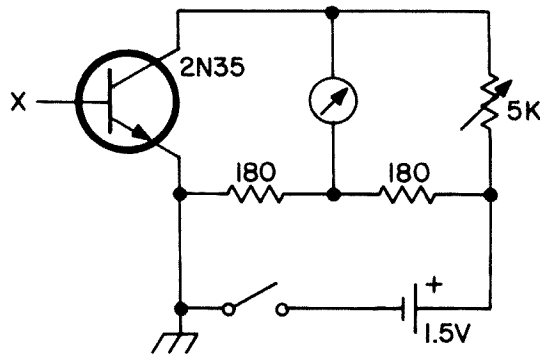

Fig. 1. Indicating oscillator circuit diagram.

The circuit (Fig.1) is not critical. However, the sensitivity control should not be bypassed. Layout could possibly be improved with a slightly larger box, allowing the dial to be placed on the face with the meter. It is a good idea to keep the layout symmetrical as far as possible, particularly the tuned circuit. This can be seen in the photo of the inside view. The box used was an LMB 532 EL with the cover reversed to allow for coil mounting insulator (polystryrene or other good rf insulating material). The meter should be a 50 μA movement; otherwise, a meter amplifier such as the one shown schematically in Fig. 2 will be necessary. This is no problem, as there is room for this amplifier on the circuit board.

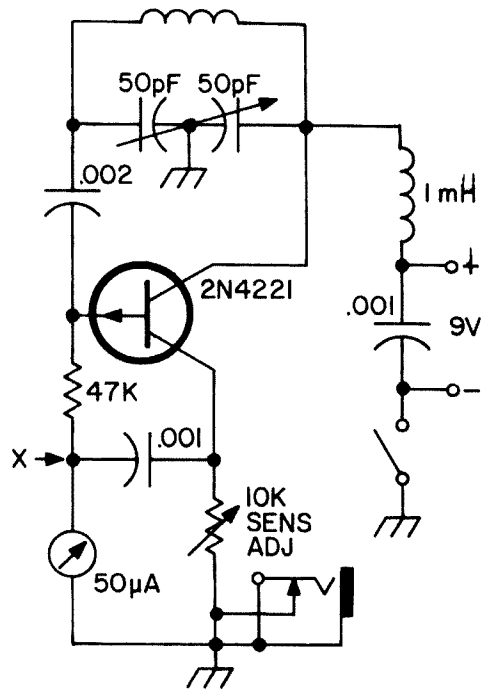

Fig. 2. This meter amplifier will increase the level of the signal so that a less-sensitive meter than 50 μA may be used.

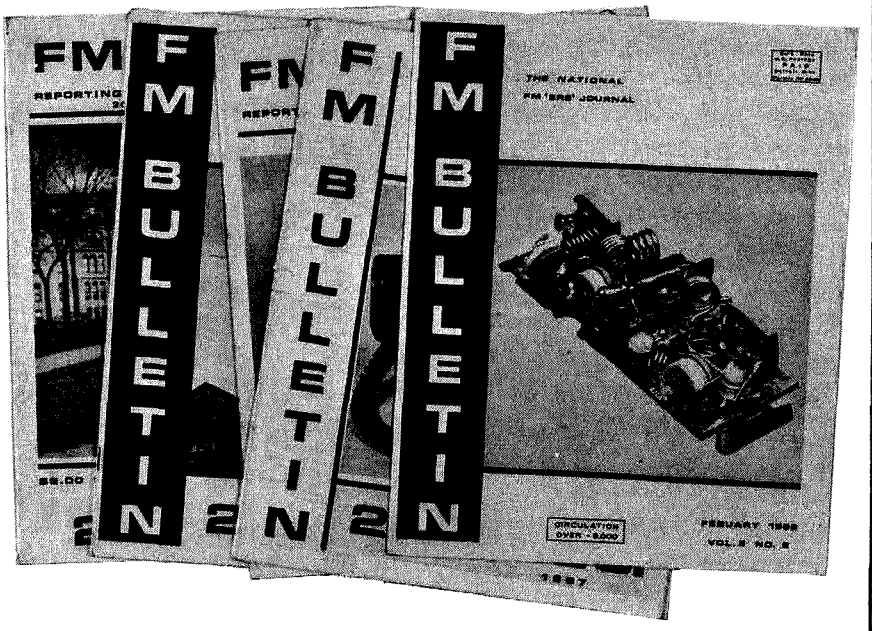
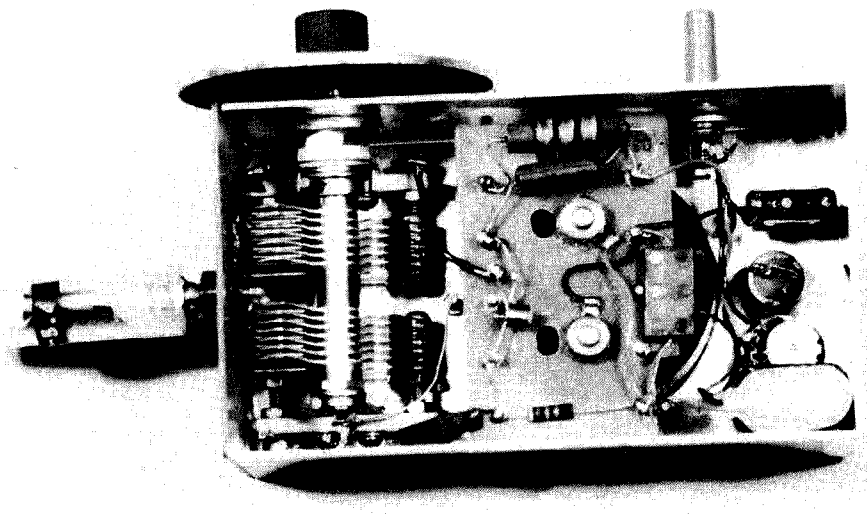
A thumbwheel from a BC-375 tuning unit could be used very nicely as a dial. Three sides have been left clear for ease in placement of unit when in use. Plug-in coils makes for easy bank change and application to the job at hand. Standard-spaced banana pins allow for use with other accessories. Use 5/8 in. polystryrene tubing and stud-type banana pins.



A dual banana plug can be used during construction for setting the spacing accurately. The coils shown have the pins wired in place for stronger mechanical assembly. Drill a hole for about 24 AWG copper wire on each side of the pin studs which will lie along each side of the poly tubing. Use a number 59 or 60 drill. One wire is enough on each pin. Form a hairpin with about an inch of wire, push it through the drilled holes from the outside. Now twist tightly with longnose pliers, cut it off short, but not so short as to allow the wire to untwist! Then apply several coats of liquid "poly" cement. Be sure to move the coils frequently during the hardening period to make sure the liquid "poly" flows evenly over the stud and forms a slight fillet with the tube. Epoxy doesn't seem to work well with polystyrene. Neither Allied nor Newark list liquid polystyrene any longer, but your neighborhood hobby shop should be well stocked.

The lowest frequency coil (number 1, 0.95–2.2 MHz) was made from a Miller 951 ferrite 0.5 mH choke with 6 or 8 turns removed – just enough to slip inside the poly tubing. Some reaming may be necessary. The number 2 coil (2.2–5.4 MHz) was made from a Miller ferrite antenna unit with the slug permanently installed in the top end and all lugs and mounting hardware removed. This coil was also mounted inside the poly tubing. The number 3 coil (5.4–13.5 MHz) consists of 32 turns of 28 AWG enameled wire, close-wound on the outside of the poly tubing. All coils are 2½



FM'ers!

LOW AND INFINITE ATTENUATOR FOR TUNING VHF RECEIVERS

One of the most useful test-equipment gadgets the homebrewer can build is a signal generator. The one described here is of commercial quality and it can be completely contained inside a waveguide. Positioning, by sliding along the waveguide, provides a variable-strength stable signal of one millivolt, one microvolt, one nanovolt, or less, dropping down gradually to a true zero. It does this in a perfectly smooth fashion without steps or jumps so that every fraction of a decibel in lower noise figure shows immediately on the slide dial. What's more, the slide can be calibrated so that FM'ers can use the device for directly measuring receiver sensitivity in tenths of a microvolt.

In building a 6 meter receiver recently for maximum absolute sensitivity I naturally had to check especially on the first-stage rf transistor and circuit for minimum noise figure. (For this type of work you *must* have a signal generator capable of being attenuated out of sight with any receiver you can buy før any money.) The usual generators on the market under $100 do not do this. And many of the very expensive generators get so leaky that they have to be used 200 ft from the receiver. At any rate, the generator described here can be made up quickly and at low cost, and it *is* stable, reliable, and infinitely variable.

Waveguide

The only possible difficulty might be in obtaining the piece of waveguide needed. The piece I used is 4¼ in. wide by 2 1/8 in. high, and is 24 in. long. If you have a choice, get a piece a little longer. You could make up this item out of brass or copper if you had to, because in this case it is not used to *carry* energy but to *attenuate* it, so the worse you make it the better!

The waveguide *must not* have any holes in it and should be reasonably smooth inside; otherwise your dial would not read smoothly in attenuation. You *could* use copper or aluminum drain pipe, although I have not tried them yet. Working directly on the rf, this attenuator is good for any kind of modulation, including SSB, FM, pulse, or what have you.

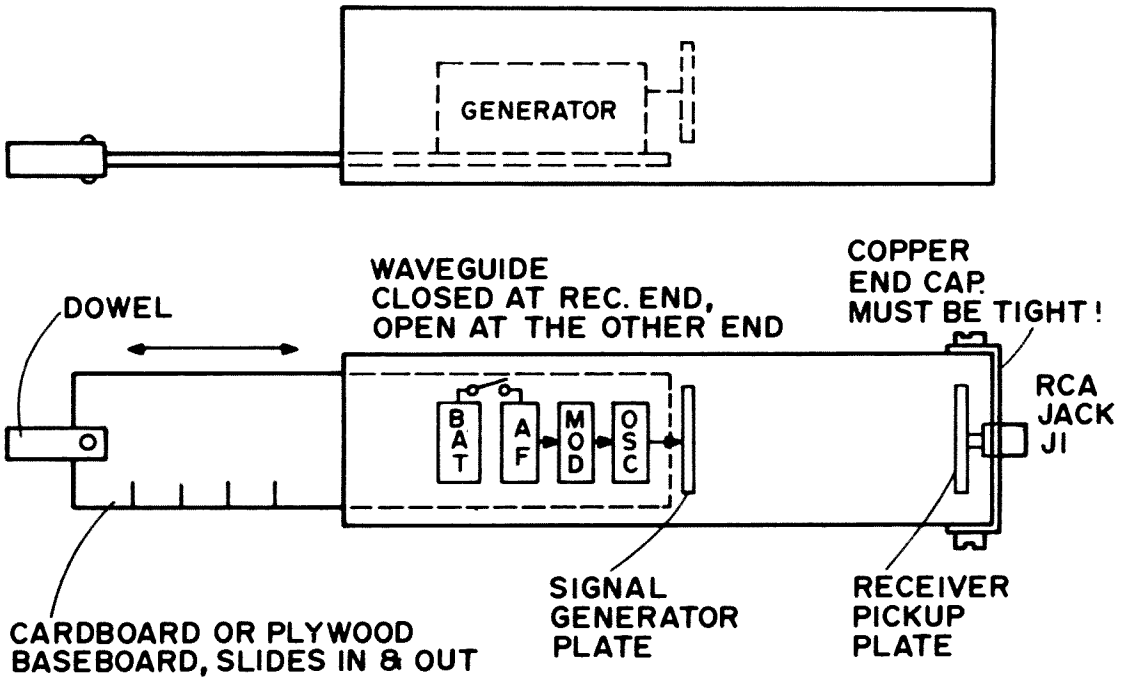

Fig. 1. Sketch shows plan-view layout of unit inside waveguide attenuator. The oscillator unit is mounted on a flat wood or cardboard strip that can be calibrated to give accurate indications of output signal.

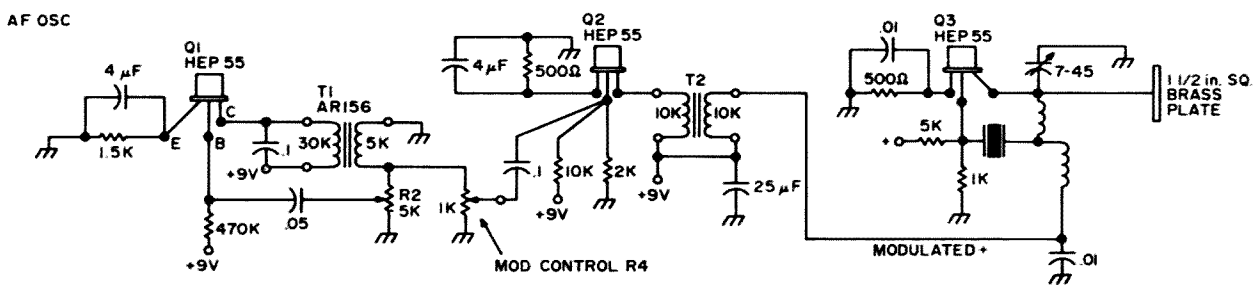
Construction

Figure 1 shows the basic idea. When the signal generator plate is close to the receiver pickup plate, you can get about 100 mV of signal into the receiver, and it is handy for checking diode receivers. When the two plates are about 8 in. apart, the signal is just detectable on a good receiver. Additional spacing between plates amounts to "waveguide beyond cutoff." I do not believe that there is any receiver in the world that can pick up the signal much beyond the 8¾ in. point.

Pretty soon in your receiver "peaking" work you get to that signal that may be but a tenth of a microvolt or so, and you begin dreaming about cryogenic front ends, masers, and such. As mentioned, every fraction of a decibel lower in noise figure, every improvement in sensitivity comes out rigorously and relentlessly on that slide dial. You can easily check which of your low-noise transistors is really low, whether that MOSFET will do a better or worse job for you, and in which circuit.

As you go up in frequency you may have to make smaller and smaller oscillators in order to fit in smaller waveguides to get the cutoff effect. (That will not be a problem if you read 73; the May issue described a "postage-stamp-sized" rf generator that is an ideal candidate for the signal source.)



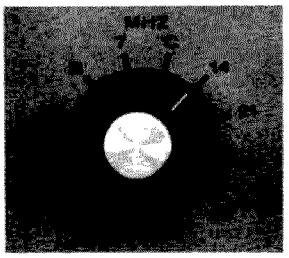


Fig. 2. Schematic of generator. This entire assembly about 3 x 4 in. including small 9V battery and switch must be entirely inside the waveguide. No wire or metal of any kind can be brought outside.

Circuit

A crystal oscillator, an af oscillator, and a simple class A modulator do an excellent job to start with. Figure 2 shows the present unit as used on 6 meters. It must be stressed again that no wire or other piece of metal may be allowed to reach the outside from this assembly. I'm making up another for 2 meters soon (still my favorite band) and will try one on 450 a little later.

Audio

A controlled-feedback transformer-coupled af oscillator does a good job in furnishing a sine wave. A Motorola HEP55 is used for the oscillator, with feedback to the base from the collector through transformer T1, controlled by resistor R2. Audio output is taken off the 5 kΩ winding of T1, is fed through R4 the modulation control, and then to the base of af modulator Q2. Transistor Q2 is set up for low-power class A operation because not much modulation is needed for the signal generator. Transformer T2 is an old 5W unit from "tube-type portable" days. The secondary of T2 feeds a modulated +9V signal to Q3, the crystal-controlled 50 MHz oscillator.

This rf oscillator is one of my negative-feedback jobs with phase reversal in the crystal. A 1½ in. square plate is tied onto the collector, radiating energy to the receiver pickup plate facing it inside the waveguide. This energy is rapidly attenuated as you move the plates apart, and should be impossible to detect after some 9 or 10 in. of separation.

Once again, do *not* bring any wires or any other metal or conductor out from the oscillator assembly. If you want an outside controlled switch or other control, bring it out as a wooden dowel handle.

That's about it. Tune everything up outside the waveguide on the bench; when you're satisfied, plug your best 6 meter receiver into J1, push the oscillator plank along the waveguide (or rather I should say pull it along) away from J1. You'll get a surprise! Hope this helps you with your low-noise receiver work. It did a lot for me.

Code Practice a la Baby Talk

I was reading the mail on 20 when I let out a groan that brought my wife, Margie, running into the shack. "What's with you?" she demanded. "And don't say it's my cooking."

"Look," I said, waving a hand toward my brand new ham receiver and transmitter built from kits, "Here I got this fine ham gear and I can't talk back to those guys because I haven't a license."

"So what else is new?"

I knew what she meant. It wasn't the first time I'd moaned over my licenselessness. I squared my shoulders, stuck out my chin. "This time I'm really going to learn the code. The theory I know. It's that goshdarn code!"

"That reminds me. You know that ham at the end of the block?"

I groaned again. "Sure I know him. He just got his Extra class ticket. He can copy twenty words a minute and I can barely copy four."

"Well, maybe you could do just as well if you used his method."

My head snapped up. "What method?"

"I met his wife in the supermarket the other day and she said that he learned code by dah-ditting everything he read."

"Dah-ditting?"

"That's right – dah-ditting. At breakfast he'd sound off labels on breakfast food in Morse code. Then on the way to work, he'd do billboards and car licenses in code. She said it was this idea that made it possible for him to pass the code test"

I thought this over for awhile, and then said, "Dah-dah-dah, dah-dit-dah."

"What's that supposed to mean?"

"OK. I'm going to try it."

And I did, the very next morning. As usual, I poked my head into the baby's room. The little tyke looked up, and said "Dah dah."

"Hey," I yelled to the wife, "the kid knows one letter already – dah dah. That's M!"

I heard a dish drop in the kitchen, then my wife's excited voice. "I hope you're not thinking that. . ."

"Well, the thought did occur that Junior and I could talk in code."

"No! Absolutely no! I want my son to talk, not dah-dah throughout life."

I could see her point. I'd be guilty of creating a human oscillator. I apologized and sat down at the breakfast table. Instead of the usual small talk, I vocalized in code the advertising material on cereal packages. I even included the recipes. At one point, I said, "Pass the dit-dah-dah-dah, dit-dah, dah-dah."

Margie's eyes went heavenward. "Oh, what did I start by giving you this dit-dah idea!"

"I only asked you to pass the jam." I chuckled. "It's a great idea. I've got a feeling I'm going to pass the thirteen-word requirement for a General license."

On the way to the office I had a great time translating billboard ads into code. Never before had I been so fascinated by car, beer, milk, and bank outdoor advertising.

When the billboards weren't in view, I'd work on car licenses and speed limit signs. It was while sounding off on a 25 mph speed limit sign that I became aware of a motorcycle cop at my left, obviously wanting me to curb my car.

I stopped, and then as the cop approached I did something out of force of habit. I dah-ditted the officer's badge number in code. He looked at me oddly. "Sorry, officer, I forgot myself. I'm studying the code for a ham license. Those dah-dits were your badge number."

He seemed more than mildly interested. In fact, I believe I detected the very faintest smile. "You were doing 30 in a 25-mile zone." He started to write. "May I see your operator's license?" Then, as if he'd just heard: "Studying for a ham license, eh? Me too."

My spirits soared. "Well, well, well! It's a small world, isn't it?"

He agreed, but went on writing.

"You'll know it's the code that stops most of us," I said. "I just learned about this method of sounding out the code while driving and thought it'd be a great idea. Maybe," I added, "you'd like to try it." I looked at him expectantly.

"No, that'd come under inattentive driving."

I groaned inwardly as he continued to write. "Glad to hear you're going to be a ham," I tried again in a different vein. "What I like about the hams is their great fraternal spirit. . .Nothing they wouldn't do for each other."

The cop nodded and went on writing. Maybe I was being too subtle. "Hey," I said, "I bet if we were hams right now we'd be slapping each other on the back and wishing ourselves good DX."

"Yeah." Just yeah, that's all he said and handed me the ticket. I shoved it in a pocket without a glance.

I was in a bad mood all day and to top it off that evening the wife greeted me with a cheery, dit-dit-dit-dit dit-dit. "That's hi," she said, obviously proud that she'd learned two letters.

"Hi to you too," I said, handing her the ticket and at the same time relating what had happened, adding, "I can't understand it. For one thing, that speed sign wasn't there yesterday, and I was only going five miles above the limit. Furthermore, there aren't any pedestrians there, and. . ."

I stopped. Margie was laughing. I became sarcastic. "How would you like to laugh all the way down to the police station and pay the fine?"

She continued to laugh. "Silly! This isn't a speed ticket. It's a warning. And the officer must like you."

"Like me?" I recalled the ice-water treatment.

"Sure. Look."

I grabbed the official form and for the first time noticed that it wasn't a speed ticket. Scribbled in a strong hand were the words:

"Suggest you use your vocal code practice method when not driving. Hope to work you on 80 CW soon. 73."

I read it once, twice, three times, and then danced around the room, singing, "Dit-dit-dit-dit dit-dit" over and over. Margie looked puzzled. "Oh," I said, "I should explain. . .dit-dit-dit-dit dit-dit is what the CW operator sends when he means "ho ho ho."

. . . W9PXA ■

3 versatile ic testers

Richard Factor WA2IKL
30 West 60th Street
New York NY 10023

As integrated circuits become widely used in industry, large numbers of them find their way into the surplus market, often at prices of a few cents each. The cheaper assortments contain many rejects and are frequently unmarked. With transistor assortments, this is not a problem, since transistors generally have three leads, and only a few trials are necessary to find out if they still "transist."

ICs compound the problem, since they not only have many more leads, but they don't all do the same thing. Figure 1 shows just a few of the many configurations available. With three simple IC testers, you can test and identify virtually all of the ICs a ham is likely to come across (including those of Fig. 1).

After the sweeping claims above, I should clarify some of the things the testers won't do: They will not rapidly and automatically test all the static and dynamic parameters of ICs. They will not automatically check such complex function units as 256-bit read-only memories and other MOS circuits. They will not test the vast assortment of rf and video amplifiers available. They will give no measurements good to 0.1%. But all three can be built for under $20; so if you don't expect the impossible, you can make up a very handy item to have around.

What the testers will do, and do quite nicely, is test RTL, DTL, and TTL digital logic circuits, decade counters, Nixie drivers, and assorted operational amplifiers and comparators, and tell you whether or not they work. And believe me, that's all you really care about.

Testing Philosophy

To test an IC, the simplest thing to do is to regard it as a black box. You apply power to it, connect an input to the proper pin, and observe whether the output is as expected. The procedure for doing this to an unmarked IC is as much an art as a science. I will describe my procedure for going through a batch of ICs. Bear in mind that this is only a representative method –

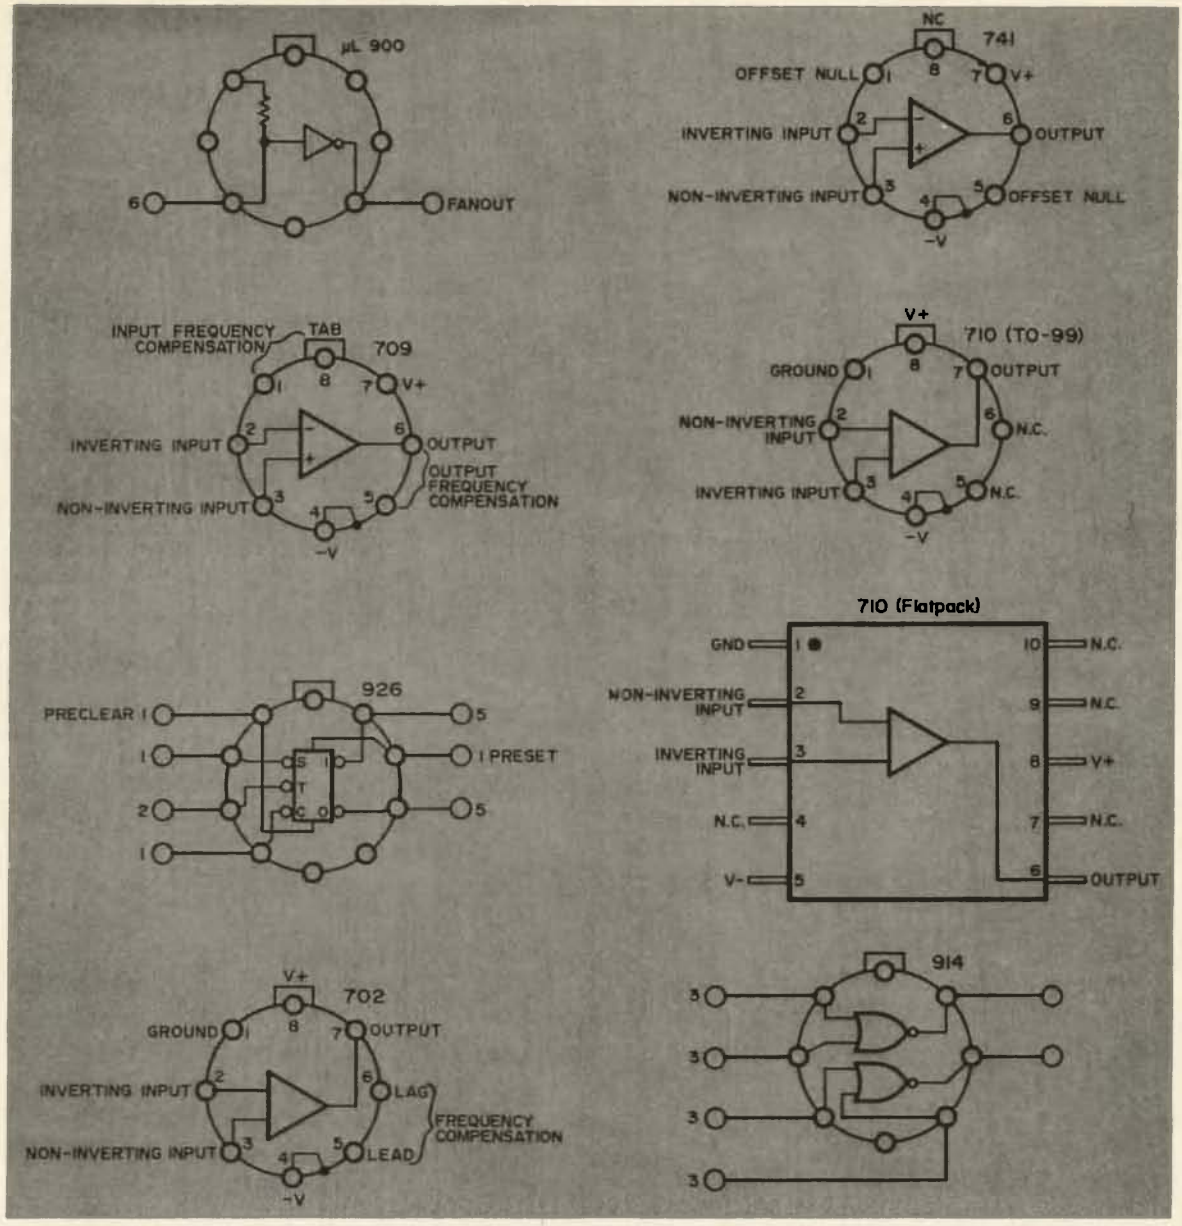

Fig. 1. Connection diagrams for some common ICs. All are shown from top view.

you might hit on one that works better for you.

Assume you have latched onto a handful of unmarked TTLs known to belong to the SN7400N series. This family has gates, flip-flops, and assorted complex functions. Since gates are the most common function, it is best to start by looking for them. Connect the patch cords so that pin 7 is grounded, and pin 14 goes to the +5V terminal. One advantage of looking for the gates first is that these power supply connections cannot damage any flip-flops or counters.

It is a very good idea to have the manufacturer's literature handy so that once you identify an IC, you can label it with a number rather than writing a truth table for it, and so you can avoid pitfalls like improper power supply connections. Insert the ICs into the socket and watch the output current of the supply. When it increases (about 5–10 mA), you have reason to believe that the IC is a gate.

The next step is to look for outputs. The easiest way to do this is to connect the scope successively to each pin while holding the tip of the patch cord. Holding the

cord puts 60 Hz on the scope input. Inputs have very high impedance, and thus the signal will not disappear when the scope is connected to one. Outputs have either saturated transistor outputs in either state (TTL), or low-resistance pullups (DTL or RTL), and will effectively short out the 60 Hz current picked up by the body. Once an output is identified, connect a pulse input to the other pins and find out which ones give an inverted output. This is now sufficient to identify the IC.

Frequently an IC will be perfectly good except for one input. If it has only a minor defect (one of four gates bad, a defective reset on a flip-flop, or such), you can break off the pin corresponding to the defect. This is much more economical than discarding the unit.

Now that we have identified the gates, let's try some other possibilities. Connecting pin 11 to ground and pin 4 to +5V is appropriate for the SN7473N flip-flop. Again, identify the outputs as above and connect the scope to one of them. Connect the pulse generator to the other pins. If you truly have a flip-flop, you should see the pulse waveform divided down to a square wave at half its frequency.

Similar procedures can be followed for almost any digital IC. Some of the newer functions are sufficiently complex to make a data sheet necessary for testing, or you may never hit on an appropriate combination of inputs and outputs. In such a case the digital tester of Fig. 2 can still make valid operational tests, although it will be of little use in identification.

Decade Counters, Nixie Drivers

Counting circuits and readout tube drivers are becoming more popular as their prices decrease. While the SN7490N decade counter can be tested by the above method, it is rather tedious, and the driver cannot be since it is designed to interface with a high-voltage device. To simplify testing of the counter and SN7441N Nixie driver, a special unit was built (Fig. 3) which simulates decade counter operation. Half of an SN7400N (or any other 2-, 3-, or 4-input dual, triple, or quad gate) is used to produce a single pulse each time the SPDT switch is closed. This steps the decade counter, and the Nixie tube is observed for proper operation. Obviously, it is necessary to have a working Nixie driver in the socket when testing the counters, and vice versa.

The 22 kΩ resistor in series with the Nixie is for current limiting. This resistor value depends on the B+ supply and the particular tube used. A rule of thumb is to select a resistor which insures that all of each digit is lit up when the corresponding cathode is grounded. The value is not particularly critical.

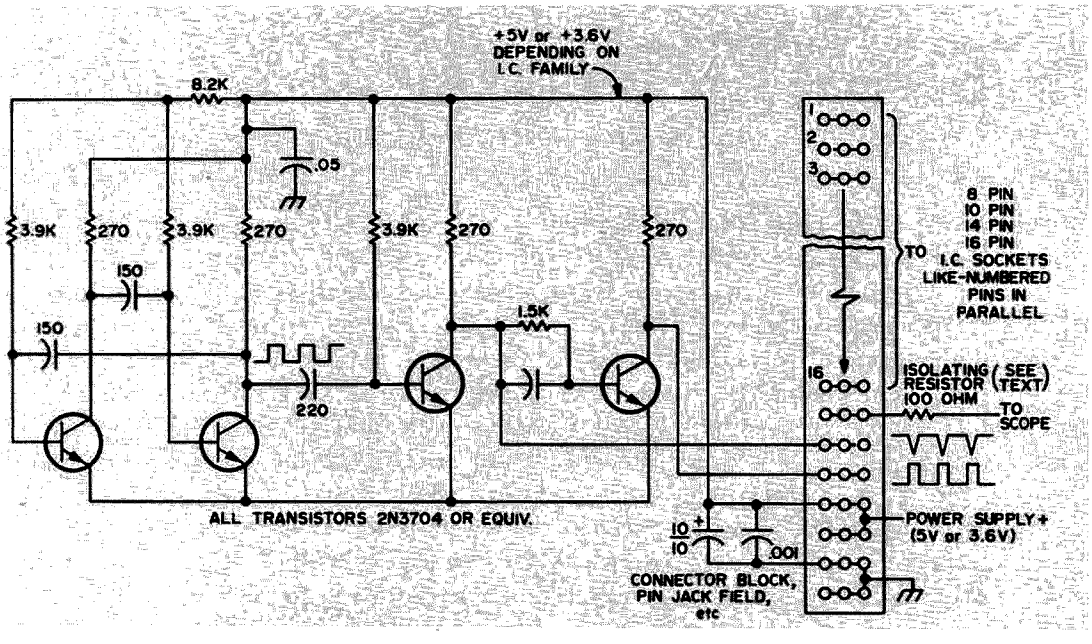

Fig. 2. General purpose digital IC tester.

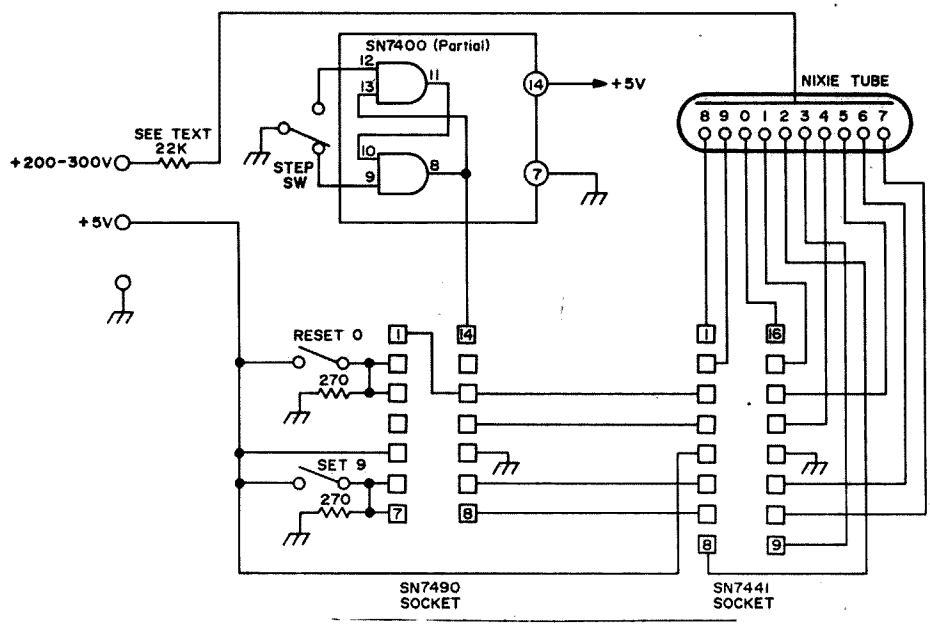

Fig. 3. Decade counter and nixie driver tester.

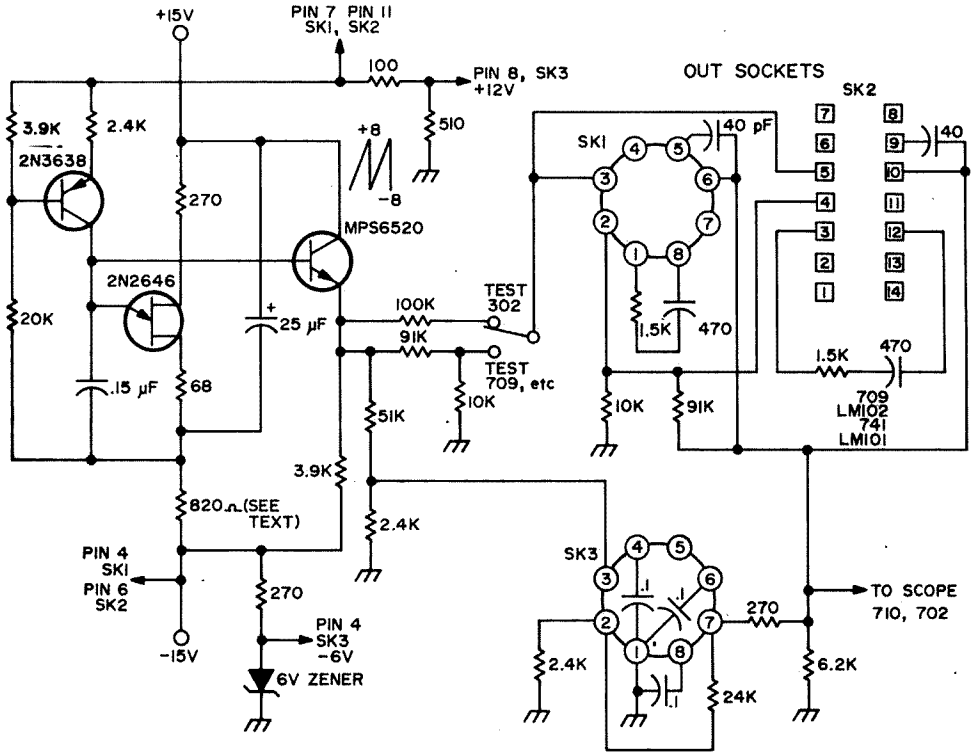

Fig. 4. Linear IC tester.

Linear ICs

Compared to digital ICs, linears are a horse from a different stable. If you have no idea what type you have, you are quite likely to destroy it during the testing procedure. They are designed for a wide variety of positive and negative voltages, and pin connections are quite nonuniform. The most useful type of linear IC is the operational amplifier, or opamp, and the most popular of these is the type 709. They are so popular that the price has plummeted from over $50 to under $2 in

reasonable quantities, and are available from numerous sources. The linear tester (Fig. 4) was designed primarily for 709 and the 710 comparator. It will also test other opamps, such as the LM101, the 702, the μA 741, and the LM102 voltage follower. The diagram showing the test-circuit equivalents (Fig. 5) gives the appropriate output waveforms to look for. The tester doesn't test for parameters such as dc offset and open-loop gain, but does provide a go/no-go test.

The unijunction and current-source transistors generate a linear sawtooth of about 16V amplitude. The approximately 820Ω resistor is adjusted so that the voltage swing is symmetrical about ground when measured at the emitter of the MPS 6520 buffer. This signal is then appropriately attenuated and applied to the device input. The 709 output should be a symmetrical linear sawtooth of 16V amplitude. The 302 output should be similar, but without attenuation. Testing the 709 without attenuation will show its peak-to-peak output swing, without delivering enough current to damage the input. A tester switch is used to control the attenuation.

Building the Testers

The diagrams are more or less self-explanatory. The only special component used in any of the testers is the patching arrangement for the digital IC tester. I used some sort of connector block into which small conical pins fit. It had been lying around for so long that I forgot where I got it. If you can't find something like this, you might try an arrangement of terminal strips and alligator clips, or perhaps a field of pin jacks. Also, while it is not shown on the diagrams, it is a good idea to bypass the power supply connections to ground as near to the IC sockets as possible, especially in the linear IC tester.

Unless you're an old pro with ICs, testing them is not as boring a job as it may seem. It is impossible to describe a complete test procedure for all digital ICs, since they fail in as many ways as there are internal components. It is highly instructive to test the ICs with both the pin diagrams and the internal schematics in

OPTIMIZING ANTENNA SEPARATION IN FM REPEATERS

by Ken W. Sessions, Jr. K6MVH

If the receiving range of your repeater can't match the output capability, the problem could be desensitization. And chances are you can solve the problem by as simple a step as moving the antennas around a bit at the site.

It was a long trip and it had seemed like an eternity since I left the last metropolitan area and all the concomitant repeater activity. I was looking forward to driving through the next big city, which I knew to be a highly populated repeater stronghold. I kept watching the roadsigns so that I could get some idea as to the coverage in miles I could expect from that famous repeater. And every so often I would key my .34 transmitter and listen for a telltale squelch indication on .94.

Just when I thought I was going to fall asleep from fatigue, I got the squelch tail I had been looking for – 68 miles out of the city! With new vigor, I hit the button and put out a call. No answer. It was only 10:30 at night, so I was pretty sure there must be at least one lonely soul more interested in chatting than in watching the evening lineup on TV. After a few more miles, I called again. No answer.

Strange. Who would think that such a renowned repeater would be so forsaken this early on a Friday night? I passed the 50-mile marker and tried again. The squelch tail was not full quieting; the delay was long enough so that I could be absolutely sure that I was making it in, however. There was still no answer.

Not one to give up easily, I tried again and again – past the 54- then the 42-mile markers. Eventually chagrined, I reached over to change my transmitter to .94 – and the first signs of life began to appear on the repeater.

From the repeater came, "Why don't you knock it off, fella. . .you're not disturbing anybody."

I gave my call again and tried to make contact with the voice.

"So keep it up," it said. "All you're doing is wearing out your finals."

Was the guy drunk? Was he talking to me?

"Hello, there," I said into the microphone. "Are you copying me?"

Then another voice came on. "Hello, Jack. . .what's up?" (Squelch tail.)

"Same old thing, Ray," the first voice said. "The lid is back playing with the repeater again." (Squelch tail.)

"Break," I said. And there was no squelch tail because Ray was talking.

". . .ignore him long enough and he'll just go away." (Squelch tail.)

"Break," I said. And a squelch tail followed.

"Go ahead the break." (Squelch tail.)

I had just passed the 35-mile marker.

"What's going on, fellows?" I said. "I've been hitting your repeater for the last 35 miles but all I've been getting is the brushoff. I thought something had gone wrong with my audio. This is K6MVH mobile – does my audio sound okay?"

"Better try again, old man. You're not quite making it into the repeater. We'll stand by for you." (Squelch tail.)

"Not making it in? Are you kidding? I've got a 15-watt rig here and I've been keying the repeater for more than a half-hour. How could I not be making it in?" I dropped carrier and heard the distinctive kerchunk.

"Did you get any of that, Jack?" Ray said.

"Yeah. . .I think it was a mobile. Hang on till you get in a little closer, old man, you're still too far out for good copy."

I was incredulous, but obedient. I drove on, listening to the two carry on their conversation. At the 21-mile mark, the road inclined for a few hundred yards, so I pulled to the side at the top and gave another call. This time they heard me, but I wasn't much out of the noise.

There was nothing wrong with my audio, I learned. And there were no problems with my transmitter or mobile antenna system. The repeater was merely experiencing a "little" desensitization. The repeater owners had put up the machine but had not yet found the cure for their desensitization problems; nonetheless, they wanted as much range on the repeater as they could get, so they set the receiver squelch to its threshold point.

The result was that the repeater users were being driven right up the walls from signals they had been attributing to "lids" and "troublemakers." They could hear the repeater being keyed frequently, but since they couldn't hear anything but garbage, they assumed each unintelligible input was a local clown.

If the anecdote sounds all too familiar, don't blush. Desensitization is far more common than you might think. It's just that when you hear about the wonders of someone else's repeater, the fellow who tells you about it generally has a way of overlooking some of the less attractive aspects of it. The truth is, the repeater I described could be any one of a dozen in the West, several in the Midwest, and a few in New England. The "mile markers" might have been different, but the situation – the lack of parity between input and output and the horrendous degree of desensitization – is strikingly uniform from one repeater to another.

There have not appeared too many articles on defeating desensitization – virtually nothing in the major journals. The measures that have been taken in most instances have been the result of dogged determination and untiring experimentation on the part of the amateurs who build the repeaters. Moreover, in the majority of installations, the problems don't seem serious enough to warrant the often rather dramatic and time-consuming effort described by the scant literature on the subject.

To minimize receiver desensitization in a typical repeater, some means must be employed to attenuate the transmitter signal at the receiving antenna location. The degree of attenuation required for any given repeater application can be predicted, however, with a fairly high reliability if certain key parameters are considered as "constants." And, since

VERTICAL SEPARATION, ft

VERTICAL SEPARATION

HORIZONTAL SEPARATION, ft

Fig. 1. Tabular listing of required antenna separation in feet for various 6 meter repeater frequency combinations. The gray area shows separation requirements for horizontally spaced antennas; the white triangle shows distances for vertically separated antennas (tip-to-tip).

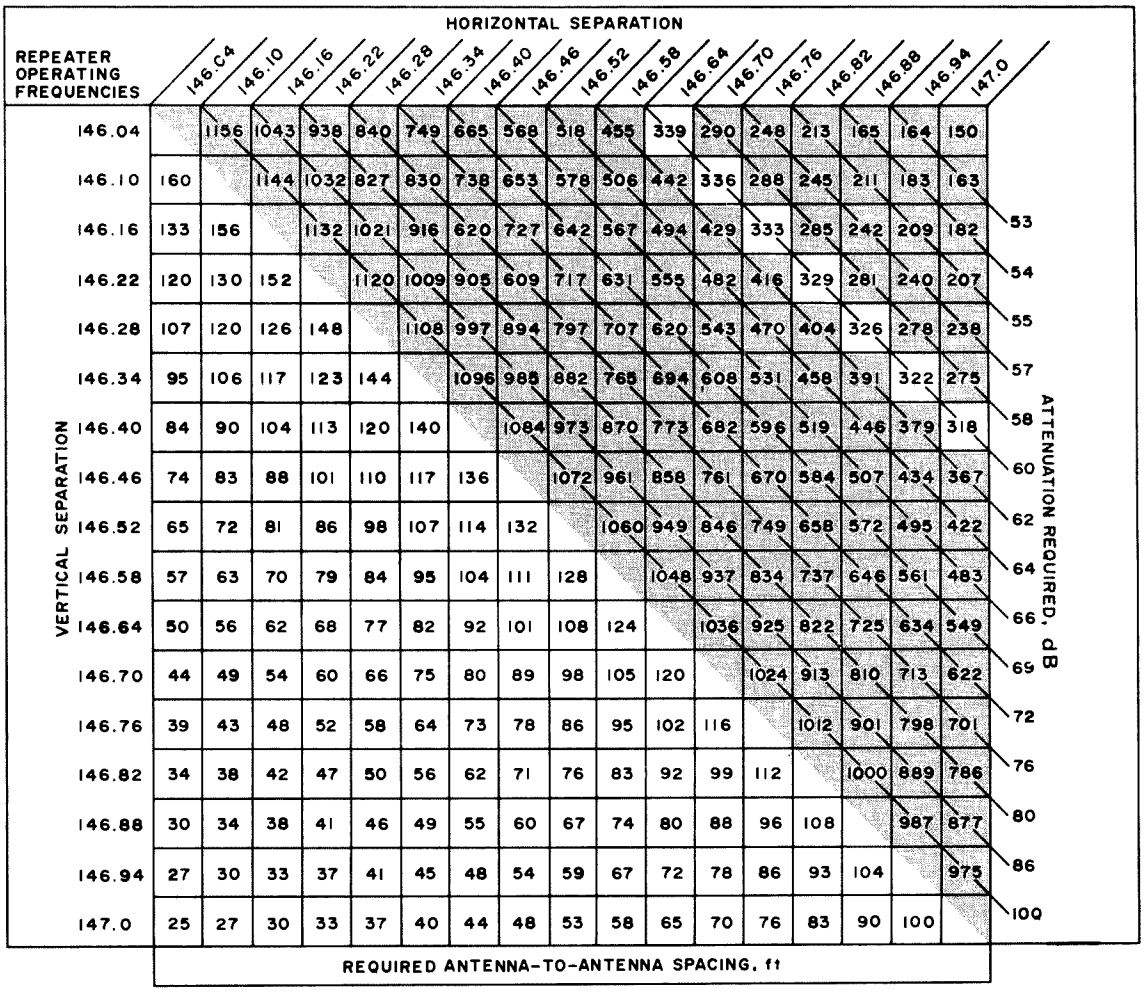

Fig. 2. Minimum tip-to-tip spacing (in feet) required between transmit and receive antennas to achieve various attenuation values. Shaded area is for horizontal separation; white area is for vertical. Diagonal lines represent attenuation level attained by tabulated separation in typical case.

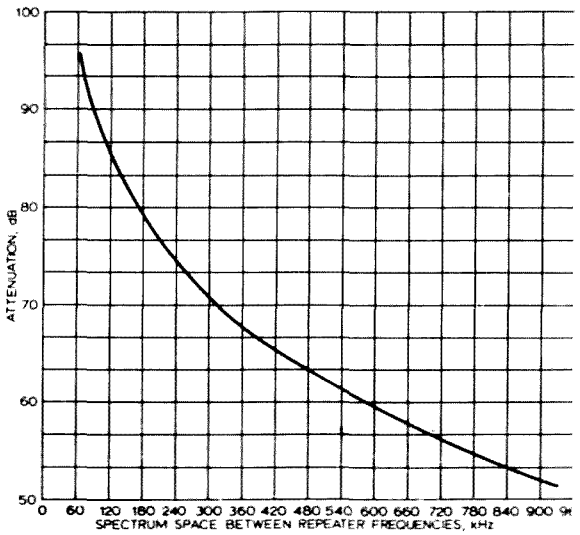
most amateur repeaters are similar in many respects, the constants aren't difficult to nail down. As rules of thumb, then, these can be considered to be: a transmitter output power of 50W or less; a receiver sensitivity of 0.5 μV (for 20 dB quieting) under normal, nontransmit conditions; use of conventional omnidirectional antennas, receiver selectivity typical of modern commercial two-way FM units, use of a well-matched antenna for both transmit and receive; and installation of high-quality, low-loss coaxial cable.

The cheapest and easiest method of minimizing desensitization is through careful separation of the repeater antennas. Assuming all the constants cited above apply to your own VHF repeater setup, you can readily determine how far apart your transmit and receive antennas must be placed by consulting the charts of Figs. 1 (6 meters) or 2 (2 meters).

Understanding Attenuation Requirements

It is easy to see from examination of the tabulated figures that the closer the repeater operating frequencies are to one another, the greater the attenuation required. With 500 or 600 kHz of spectrum between the two frequencies – as with most of the 2 meter repeaters – some means must be employed to attenuate the transmit signal by about 60 dB (shown by diagonal line on Fig. 2). If no other method is used to obtain this isolation, it can be effected by placing the two antennas some 50–60 wavelengths



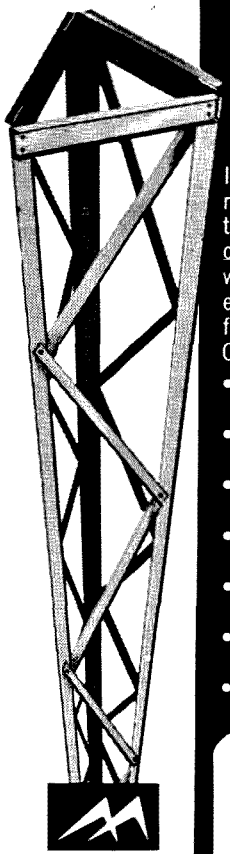


Fig. 3. Attenuation curve shows how isolation problems can be simplified by providing more spectrum between the repeater operating frequencies. As shown, the attenuation requirement gets extremely severe whith close-spaced channels.

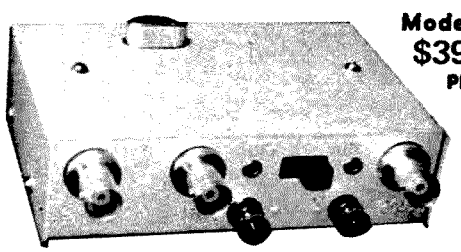
apart horizontally or by spacing them about 8 wavelengths vertically.

Since the spacing is directly proportional to wavelength, the higher frequencies require less distance between antennas to achieve a given isolation value. It is easier, for example, to isolate 146.94 from a 147.00 MHz transmitter than it is to isolate 146.70 from 146.76 MHz, even though the spectrum between the two sets is the same (60 kHz). From Fig. 2, 100 ft of vertical separation is needed between the antennas on the top end of the spectrum, and 116 ft is required to give the same degree of attenuation for the lower set.

The curve of Fig. 3 shows the attenuation required as a function of spectrum spacing between the two repeater operating frequencies. When you consider that each 6 dB of attenuation represents halving the field strength (in measurable voltage) at the receiving antenna, it is not too difficult to see why repeater owners keep the transmit and receive frequencies as far apart as possible. Consider the attenuation requirement for a 60-kHz-separated repeater, for example, as compared with a repeater system with operating frequencies spread by 600 kHz. As the frequencies are brought together, the

AL SERIES ALUMINUM TOWERS for uhf - vhf

Ideal for mounting industrial, commercial, citizens band, amateur, or television receiving antennas. Exceptional strength in proportion to weight qualities. Easy access to equipment mounted on the Microflect top mast extension.
Other features are:



- 10 to 120 feet high in easy to erect 10 foot sections.
- Available factory assembled or in kit form.
- Lightweight all aluminum 10 foot sections weigh only 12½ lbs.
- Low maintenance, will never rust or require painting.
- Staggered ladder treads for easy climbing.
- Can be used for direct radiator at HF.
- Wide variety of mounting brackets and accessories available

THE BEST
2 METER
CONVERTER

Model 407
$39.95
ppd.

144-146 MHz in. 28-30 MHz out
or 146-148 MHz with a second crystal
Available at $4.95 each.

A full description of this fantastic converter would fill this page, but you can take our word for it (or those of thousands of satisfied users) that it's the best. The reason is simple—we use three RCA dual gate MOSFETs, one bipolar, and 3 diodes in the best circuit ever. Still not convinced?Then send for our free catalog and get the full description, plus photos and even the schematic.
Can't wait?Then send us a postal money order for $39.95 and we'll rush the 407 out to you. NOTE: The Model 407 is also available in any frequency combination up to 450 MHz (some at higher prices) as listed in our catalog.

*New York City and State residents add local sales tax.

VANGUARD LABS

Dept. H, 196-23 Jamaica Ave., Hollis, N.Y. 11423

attenuation requirements get downright formidable.

If your tower will not permit the minimum separation distance as determined by the charts, you will have to plan on either more spectrum between the transmit and receive frequencies or incorporation of additonal isolation measures, such as cavities or hybrid rings. The only other alternatives are placing the receiver site physically at some distance from the transmitter or separating the two antennas horizontally by mounting them on two different towers.

It should be understood that an isolation factor of 60 dB (which the 600-kHz-spread figures are based on) is a minimum, and it results in a desensitization level of about 2 dB – a value considered acceptable by most amateur and professional repeater men.

Horizontal separation is usually a last resort because it may take as much as ten

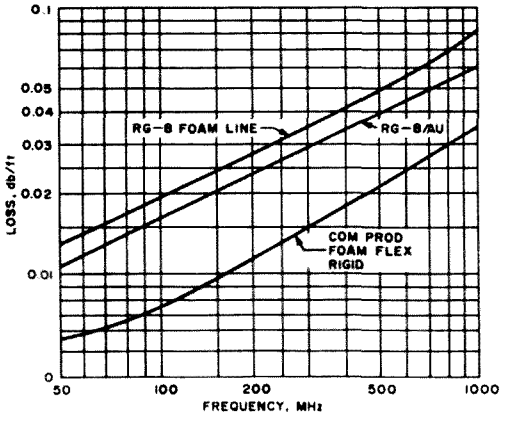

Fig. 4. This chart shows the superiority of foam line over conventional RG-8A/U cable. For a 100 ft run there is 0.5 dB less loss with their "equivalent" foam line at 150 MHz, and only 1 dB of total loss with ComProd's rigid foam line.

times the distance horizontally that it takes vertically to achieve a given attenuation level. In the 60 dB attenuation example above, for instance, a vertical separation of only 45 ft does the job. If the antennas are to be separated horizontally, however, the physical spread between the two antennas must be increased by no less than 322 ft. This characteristic is attributable to the fact that antennas typically radiate most of their energy in an almost perfect horizontal plane. Not only does the transmit antenna pump out more radiation horizontally, but the receiving antenna is pulling in signals better along that plane. With vertical separation, though, both antennas are placed in a position least susceptible to direct radiation of the other.

Another major disadvantage of horizontal separation with a single-site repeater is the excessively long runs of transmission line usually required. No matter what type of coaxial cable is used, a 400 ft run means plenty of signal loss – particularly at the higher frequencies. Figure 4 shows just how much loss you can expect with RG-8A/U and foamline equivalents at the various VHF and UHF frequencies of interest to amateurs. At moderate power levels, extremely long runs of conventional coax would seem almost prohibitive, even at 150 MHz. A figure of 0.025 dB/ft for signal attenuation may not seem like much, but it results in a 10 dB loss with a 400-ft length of transmission line – which is a power loss of a full order of magnitude, turning fifty watts into a measly five.

Use of a very high grade of line, such as Communication Products' rigid Foam-Flex, will cut the loss to about 1 dB per hundred feet; a better alternative, of course, but still a significant loss. And consider the cost of a 400 ft length of this "good stuff." It isn't cheap!

Clearly, horizontal separation of antennas is not a sound solution from a single site under ordinary conditions, particularly on the lower VHF frequencies.

All this discussion is not meant to be a course in repeater planning; the object is merely to help you determine the best possible way of providing good solid repeater coverage using only the facilities that you have available.

Tricks You Can Do

If you looked at the vertical separation charts of Figs. 1 and 2 and decided that there was not enough room on your

tower to accommodate both your repeater antennas, don't resort too soon to going the horizontal route. There are still a few more aces you can play.

Many service specialists – both commercial and amateur – are surprised to learn that when "gain" antennas are spaced vertically, one or the other of the two may be moved a few inches *horizontally* to yield an *effective* increase in separation distance and a positive improvement in signal isolation by as much as 3 dB. This interesting phenomenon can be explained on the basis of the radiation-pattern peculiarities of individual antennas (though virtually all of the collinear omnidirectional antennas are similar). From the typical pattern of Fig. 5, you will notice that a collinear omnidirectional gain antenna produces lobular "spikes" below the radiator and along the same axis. Most antenna manufacturers publish typical patterns (as in Fig. 5a) that show a symmetrical placement of these minor lobes. In practice, however, these lobes are not necessarily symmetrical, even though they are always present. Their appearance will depend on such factors as antenna placement, distance from tower, size of mast, etc., and they will rarely form the symmetrical arrangement sketched in Fig. 5a. The measured pattern will form a hodgepodge of lobe spikes as pictured in Fig. 5b.

If the lower antenna is positioned at the null between these spikes, maximum attenuation will result. If the lower antenna is centered on one of the lobes, however, adequate isolation may be very difficult to achieve. A few inches to a foot laterally may make all the difference in the world!

One excellent way to determine the best position for the second antenna is to take actual field-strength measurements at various candidate locations on the tower while the transmitter is pumping a signal into the first (mounted permanently). For vertical-separation checks, load the transmitter into the upper antenna (even though it may eventually become the receiving antenna), then do a thorough job of checking the field strength of the signal at various positions lower on the tower. When an optimum location is found, mount the antenna there loosely, then connect it directly to the field strength measuring device. While monitoring for a null, move the antenna as much as possible within its confines. Then secure it when the reading is optimum.

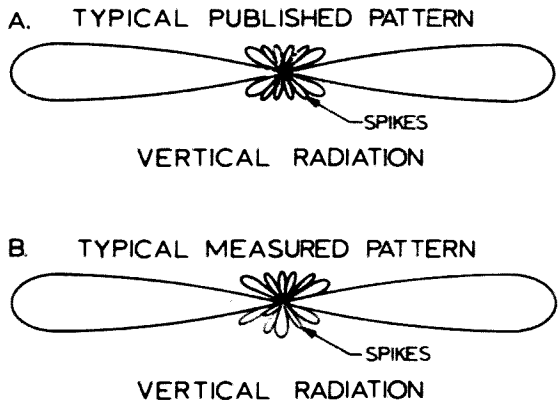

Fig. 5. The measured radiation characteristics of an antenna will often differ from that specified, particularly with the minor lobes directly above and below the radiator. Published patterns show symmetrical minor lobes with a null directly above and below the antenna. Actual measurement may show nulls slightly off-axis from the radiator. Experimentation with one of the repeater antennas will quickly show where the null points are.

Another trick in common use is the inversion of one of the two vertically separated antennas. With gain antennas, this procedure may not offer some of the fallout advantages to be realized with groundplanes because most gain antennas have a characteristic radiation in an almost perfect horizontal plane. So there is rarely an actual signal improvement when a gain antenna is inverted, but the reduction in desensitization can certainly make it worthwhile. If the vertical lobes of the upper gain antenna (that is, the spikes extending directly below the upper antenna) are difficult to avoid with the lower, turning the *top one* upside-down and jockeying for position will almost certainly cure the problem, *provided the tip-to-tip spacing between the two antennas can be preserved.* If the tip-to-tip spacing must be compromised by invert-

ing the higher of the two antennas, it might be wisest to try inverting the lower one. This tends to increase tip-to-tip spacing, but could cause problems of interference with other structures if the lower antenna is mounted in the vicinity of a rooftop, the ground, etc. Individual installations will have to be made on the basis of these considerations.

An important note: When a gain antenna is inverted, great care must be taken to insure that *absolutely no moisture* gets into the fiber-glass casing. A little water and you can kiss your expensive antenna goodbye.

Groundplanes make particularly good antennas for inversion because they characteristically have a very high angle of radiation (generally about 23 degrees above the horizon). Inverting the *lower* one will provide the highest degree of signal isolation, and will probably get you a little extra gain on the low horizon because of the change in primary radiation angle. Inverting the upper one may or may not help your desensitization, but it will certainly improve your radiation angle. Your best bet is to try it both ways – first the lower antenna, then the upper one. At least with groundplanes, there is no need to fear compromising the tip-to-tip spacing between antennas.

The Last Step

There is still one other repeater improvement technique that can be employed, but it is the one least used by repeater people. It takes practically no effort, and results in a system that is greatly improved in terms of actual usefulness. The trick? Nothing more complicated than a simple adjustment of the repeater squelch. But for some reason – no doubt intrinsically involved with ego in some way – repeater owners are all too frequently quite reluctant to do it.

The rule is this: Don't set a loose (sensitive) repeater squelch unless the transmitter can reproduce a weak input signal without degrading the performance of the receiver. The problems I incurred during my trip could have been avoided completely if the local repeater talent had adjusted the repeater squelch to a realistic level. When my signal was too weak into the system to overcome the desensitization problem, it should have been kept from being repeated and providing an annoyance to the local stations who monitor the frequency. Repeater owners should bear in mind that even if a repeater can be activated by a weak station, this is not necessarily a guarantee that the output signal will be copyable by the users. And there is nothing so disconcerting as a repeater being constantly keyed by unintelligible signals.

Many convention-goers found this out at the recent Orlando hamfest when a hastily installed repeater was set to retransmit threshhold signals. A number of walkie-talkies were turned off because of the annoying and unintelligible garbage that was being relayed the first night. A flick of the wrist at the receiver on the second morning of the FM convention, however, cured the problem, and the repeater was once more the useful and enjoyable communicationns medium that it was designed to be.

In short, if the range of the receiver doesn't match that of the transmitter, look for excessive desensitization. If you seem to have that problem whipped and the range imbalance still exists, try lowering the transmitter power. This will achieve the dual purpose of dropping whatever desensitization that may still exist and effectively bringing the range of the transmitter in to more closely approximate that of the receiver. Finally, set the squelch on the receiver so that those signals too weak to be copied do not even get repeated.

The result? Your repeater will be as busy as ever, but with cleaner signals – and you'll find more people monitoring more often during the inactive periods. But most important, your repeater may get the reputation for having input and output coverage that is ideally balanced. What better compliment to your system than to have people say, as they do of the Buffalo repeater, "If you can hear it, you can use it!"?

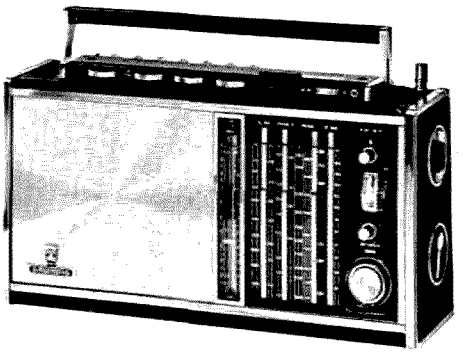
More Notes on Diode Stacks



While reading K6KA's excellent article on diode stack power supplies (73 Magazine, September 1969), I thought of a recent experience I had where I replaced two 3B28's with silicon rectifier stacks. The particular power supply used was a 3 kV centertapped transformer, 8 μF oil-filled capacitors, and a 50Ω current-limiting resistor. A relay in the primary of the transformer is connected to the push-to-talk relay in the transceiver and push-to-talk operation is normally used.

I obtained some GE rectifier modules (Part A1423) rated for 5 kV at 300 mA and substituted them for the tubes. The only special precaution I took was to keep the leads short. No special transient suppression circuits were used and the power

GRUNDIG SATELLIT-AMATEUR 210

Yes, it copies Sideband and CW too!

FOR SHORTWAVE A highly sensitive receiver whose selectivity can be switched to wide or narrow for optimum results on sideband or AM. And for serious DXing, just plug in an external antenna.

FOR FM Hi-fi quality through broad bandwidth, high-power audio, and multiple speaker arrangement.

FOR SWL Easy tuning on a number of selectable bands. This receiver is sensitive enough to pull in even the weak stations without an external antenna.

supply has been operating satisfactorily for about six months. The photo of the rectifier module shows its small size.

Higher voltage stacks are available from GE in the same package; however, I recommend using two of the 5 kV stacks in series to obtain higher voltage ratings, as necessary. Use of a voltage rating considerably above the peak voltage to be expected will insure a long trouble-free life.

The units are relatively inexpensive (about $4 each) and are advertised to be avalanche-protected. As with any semiconductor rectifier, the factor limiting the current rating is the heating of the junction, which is caused by the forward current and the voltage drop across it.

In order to safely exceed the current rating of a rectifier or module, the heat must be removed. The easiest way to do this is using short leads to a heatsink; other ways are by heatsinking the body of the unit, by blowing cold air past the unit, or by adding radiating fins.

Most rectifiers are rated at a temperature above room ambient and this adds a little leeway in the current rating. For example, the 300 mA rating of the 5 kV module referred to earlier is at 50° C and ½ in. lead length, at 25° C the rating is over 350 mA. With single sideband equipment, rectifiers get a chance to cool between voice peaks and most power supplies are full-wave, which reduces rectifier heating somewhat.

The usual cause of failure in low-current silicon rectifiers is loss of blocking capability rather than forward current overload. Loss of blocking capability is often caused by voltage transients exceeding the rating of the rectifier – hence, the recommendation for a large voltage safety factor.

Avalanche- or transient-protected rectifiers will usually handle a small amount of power in the reverse direction, where small voltage pulses may be higher than the rating; however, it is much safer not to operate close to the voltage rating.

I have had good luck with these rectifier modules even though I'm probably not using them as the manufacturer intended.

DELUXE RECEIVER GAIN CONTROL

It is well-known that for obtaining optimum gain and noise figure, the front-end of a tube-type high-frequency communications receiver should emloy a high-transconductance sharp-cutoff pentode run at maximum gain without agc. However, most commercial receivers use a variable-μ pentode for the convenience of easy gain control.

When I pulled out the 6SG7 amplifier in my receiver and directly substituted a 6SH7 sharp-cutoff pentode, the improvement in the sensitivity and noise figure of the receiver was truly remarkable. The plate voltage was 250V and the screen voltage 100V. A cathode bias resistor of 100Ω was provided and agc was disconnected from the first stage.

This improvement in performance, however, is accompanied by a drawback. With strong signals, there is overloading of the mixer, resulting in distortion and audio splashing. This can be eliminated by inserting a separate gain control in the form of a potentiometer in the cathode line of the rf amplifier. Although the range over which the gain of a sharp-cutoff pentode can be varied without curtailing its signal-handling ability is limited. sufficient variation in gain does occur to prevent overloading of the mixer with strong signals.

When using a sharp-cutoff pentode in the front end, the ideal way of controlling the receiver gain is therefore to run the rf amplifier at full gain on all but very strong signals, and reduce the gain just to the extent necessary on strong signals. Figure 1 shows a circuit in which the rf gain of the

front end is electronically locked to the i-f gain and tracks with it in the desired manner. The circuit needs just one transistor, a zener, three resistors, and a bypass capacitor. The values of the three resistors shown in the figure should be taken only as a rough guide; for every receiver, the proper values of the resistors are to be determined experimentally, as explained below.

To start with, a 10 kΩ potentiometer is temporarily used as a separate rf gain control. A very strong signal is tuned in and the gain control is backed up until all traces of front-end overloading disappear. The resistance of the potentiometer then gives R1. The corresponding cathode bias will be of the order of 4–6V.

R2 determines the cathode bias at full gain. Its value depends on the tube and transistor characteristics and should be determined experimentally so that the cathode bias at full gain is the recommended value for the tube (−1.0V for 6AU6 and 6SH7; −2.0 volts for 6AH6 and 6AC7).

V1: 6AH6, 6AU6, 6AC7 OR 6SH7.
V2, V3: 6BA6, 6BG7 OR 6SK7.

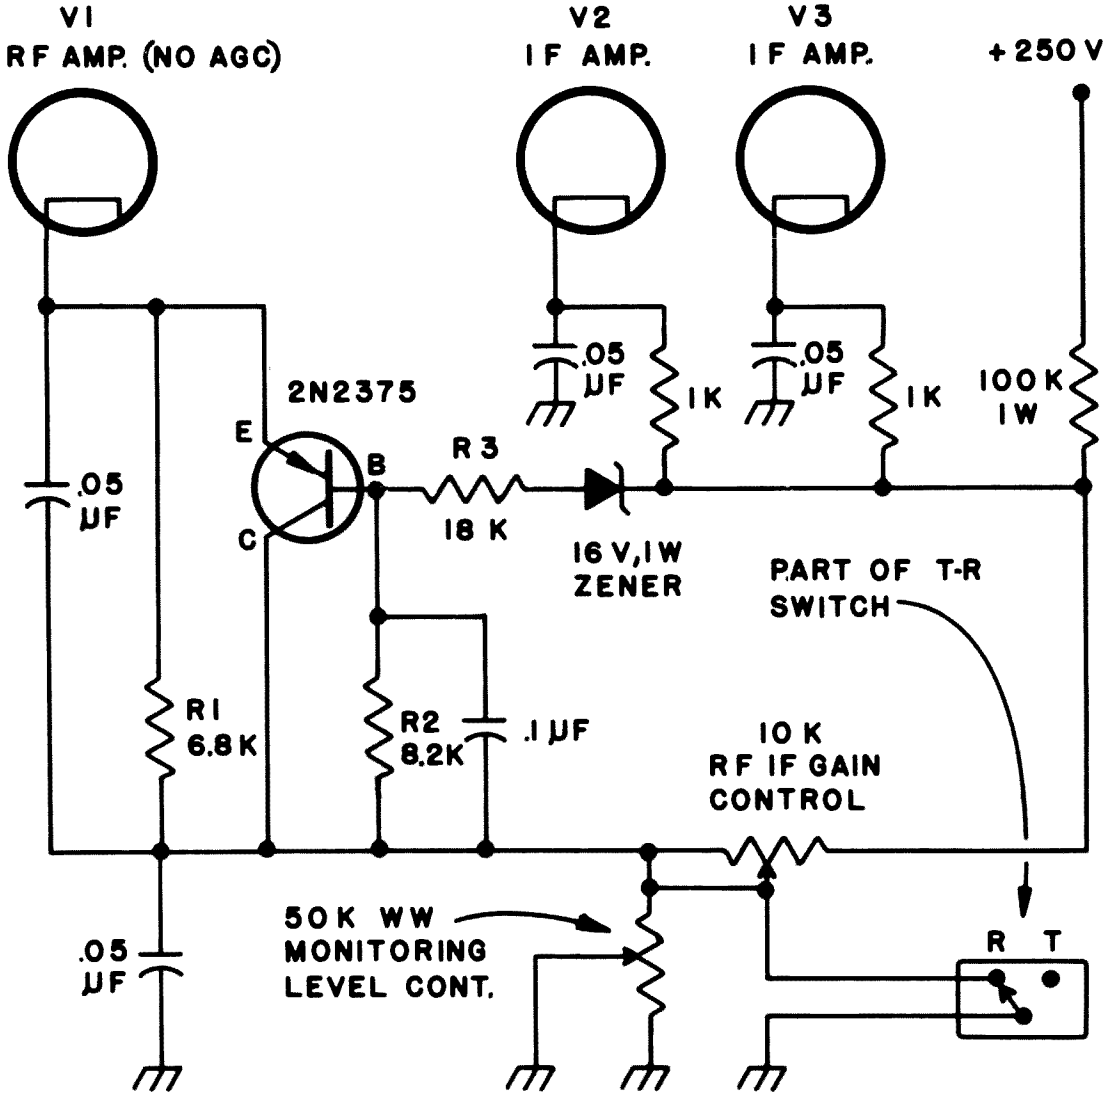

Fig. 1. In this circuit the front-end gain is "locked" onto the i-f gain and tracks with it.

The zener determines the bias voltage at which the rf gain begins to track with the i-f gain. Zeners in the voltage range of 16–22V will be in order. I did not encounter any noise or avalanche problem in using the zener. As the bias voltage of the i-f stages rises, the zener current increases the base voltage of the transistor and lowers its conduction, thus raising the cathode bias of the rf amplifier.

R3 governs the tracking of the rf gain with the i-f gain. Its value should be such that with the gain control at minimum, the cathode bias of the rf amplifier just approaches the maximum usable bias determined at the outset.

The transistor used should be a low-leakage high-gain PNP germanium transistor. The 2N2375 which I used showed an I_{ceo} of less than 100 μA and a beta of 100 under normal test conditions. Since the transistor has practically negligible collector dissipation, it is able to survive in the very unfavorable surroundings inside the receiver chassis!

In the transmit position, the 50 kΩ monitoring level control comes in series with the rf gain control. This overbiases the i-f stages while the rf amplifier, in view of its sharp-cutoff characteristic, gets completely cut off. This permits comfortable monitoring of the transmitted signal.

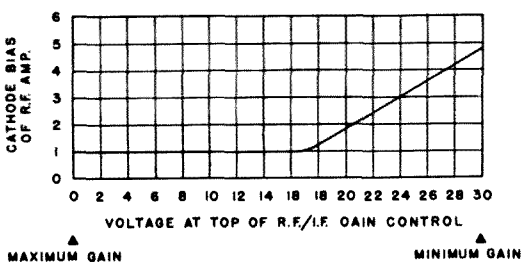

Fig. 2. Tracking curve shows smooth voltage transition with increased voltage bias.

Figure 2 shows the observed smooth tracking of the rf stage bias with the i-f stage bias. Flattening of the right end of the curve due to the transistor getting cut off can be avoided by increasing the value of R3. The performance of this gain control leaves little to be desired.

A New Approach to Communications Equipment

New amateurs are aware of the cost to develop new pieces of amateur equipment. This cost can sometimes run into millions of dollars. Most amateurs are aware of the high cost of quality equipment with all the features they might want. The three traditional methods of beating this high cost: buying used equipment, building your own, or modifying surplus; each leaves something to be desired. Additionally, improvements in circuits and various other changes tend to leave the amateur with the choice of extensively modifying complex equipment or buying new gear. This need not be. There is an approach to designing communications equipment that can significantly reduce these problems, while providing almost infinite flexibility.

In my field of high energy physics, experiments are controlled and results recorded by racks and racks of electronic modules. Since each experiment is quite different from any other in logic and control, this equipment is assembled from small plug-in modules of simple logic functions which can be connected in an infinite variety of ways. This same approach should be used in communications equipment.

Figure 1 is a block diagram of a typical SSB transceiver. Note how it can be broken down into a simple group of functions. By placing different functions in different plug-in modules, a very flexible piece of

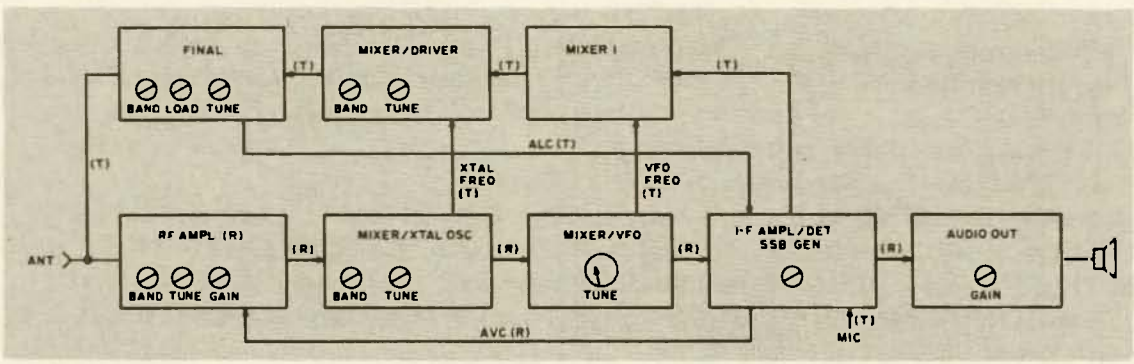

Fig. 1. Block diagram of a typical SSB transceiver.

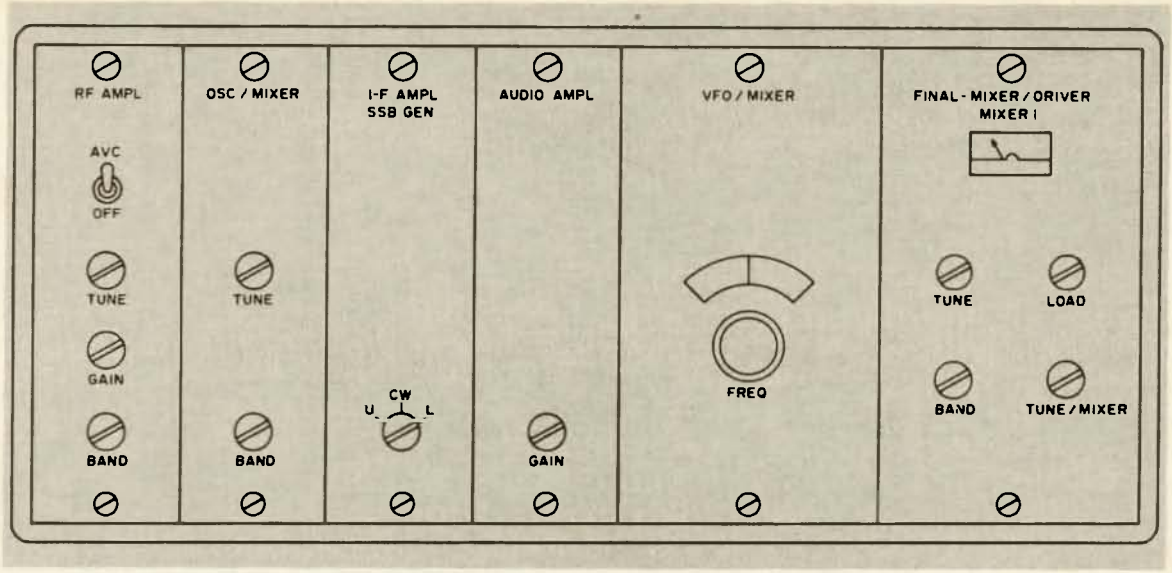

Fig. 2. Front view of a typical SSB transceiver.

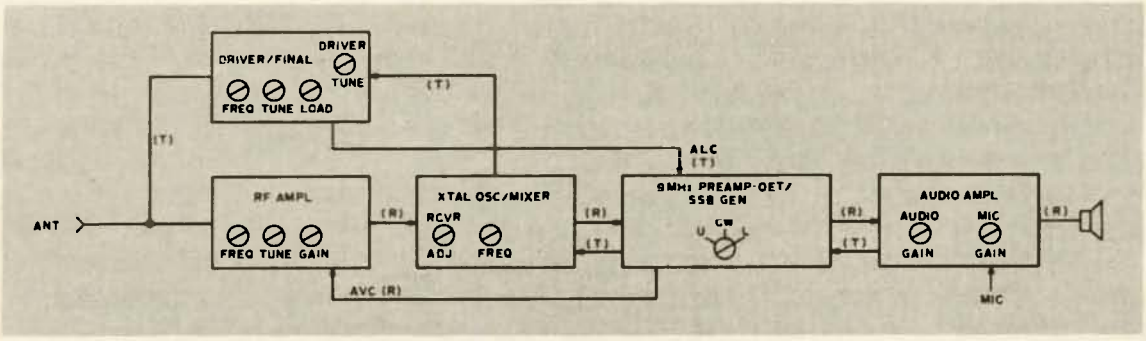
equipment emerges. Figure 2 is a front view of such a transceiver. Several functions are combined in some of the modules to fit into one chassis. If separate chassis are used for transmit and receive, some of the modules would need to appear in only one and serve both chassis if desired. If the chassis design, connector, and signal specifications are standardized among various manufacturers, then any module purchased from any manufacturer or one made at home can be used interchangeably. The user can purchase only those functions he wishes to use and not be required to pay for undesired capabilities. He may choose to purchase each module from a different manufacturer or build his own, depending on which is most appropriate for him. Men who like to experiment may easily replace a module such as the rf with his own creation instantly for direct comparison. This standardization would drastically reduce the development costs of new equipment. Manufacturers could concentrate on building better and less costly modules to perform the many different functions various hams desire. It would drastically reduce the problem of converting to other uses, such as MARS, military, RTTY, TV, or whatever, simply by plugging in the appropriate modules.

Figure 3 is a block diagram of a crystal-controlled 3–30 MHz transceiver for AF MARS presently under construction with this approach. As an example, Fig. 4 is a photograph of the component side of a complete 9 MHz SSB transceiver on a small printed circuit board. One LM-173 integrated circuit serves as a complete SSB/CW receiver with 9 MHz input and audio output with avc. The other LM-173 integrated circuit is an SSB/CW generator with 50 mV audio input and 9 MHz SSB output with alc. A McCoy filter is mounted on the



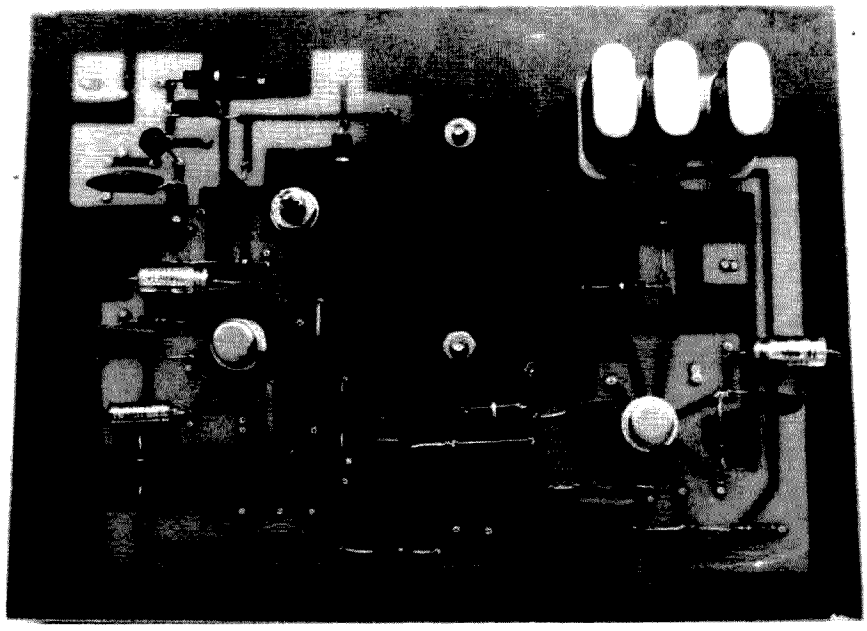


Fig. 3. Block diagram of A. F. Mars transceiver.

other side of the board for maximum isolation. The board could have been made much smaller, but I like lots of room between components for better isolation in such circuits. With the use of ICs and functional isolation, small, compact, and inexpensive modules may be constructed.

Component side of a 9 MHz SSB transceiver.

In order to make this approach work, some agreements must be reached. I might suggest the following: Although most of these circuits will be solid state, room should be left for those who prefer tubes. Actually, most of the space requirements are dictated by control functions and connectors, not the circuits themselves. In order to prevent the need for expensive, complex controls, a fair amount of front panel space should be available. At any rate, for what they are worth, here are my recommendations:

Front panel space: 16" wide x 6" high.
Module width: 2" single, 4" double, etc.
Power connectors: Blue Ribbon 24 pin every 2"
Module depth: 6" – Rack depth: 8"
Rf signal connectors: BNC
Power supply connections:

Pin: 1 ground	13 alc
2 +24 vdc	14 avc
3 +12 vdc	15 ground
4 ground	16 ground on transmit
5 6.3 ac	17 ground on receive
6 6.3 ac	18 receiver audio
7 ground (6.3 ac return)	19–24 spares
8 -100 vdc	
9 ground	
10 +150 vdc	
11 +250 vdc	
12 ground	

These pins are simply "reserved" for these voltages. They need not be supplied if not needed. For all solid state units, it is recommended that only the +12V be used so mobile operation may be used easily. Final high voltage to final (+750V) is supplied to that mobile on a separate connector.

Anyone could get into the communications equipment business by simply producing the racks first. Then they could add module chassis, power supplies, and modules as they grew. Fierce competition would drive prices down eventually, however, and should result in high quality, very flexible equipment at much more reasonable prices. System design costs would virtually disappear. Testing costs would also be reduced drastically, and fault isolation for the average ham much easier.

All in all, I feel it is the ideal approach to low cost, high quality, communications equipment, which can be assembled simply to perform any desired functions within the desires and budget of each user. It should also stimulate a lot of interest in homebrew to see if we can better the commercial boys and build a better "mousetrap" without undertaking a whole major project at once, thus improving our technical ability piece by piece.

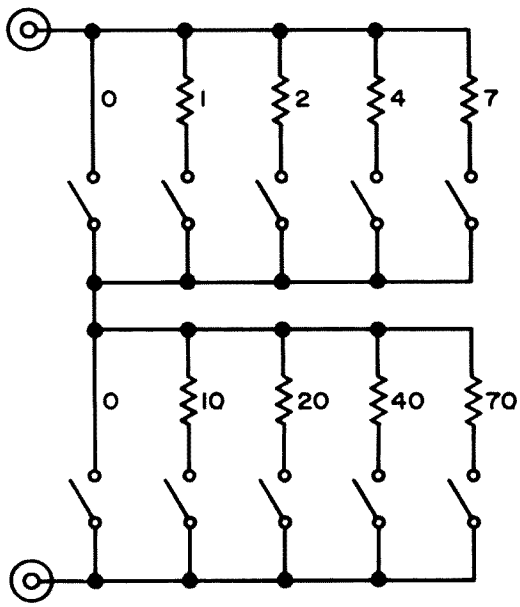

Fig. 3. Toggle switches and additional resistors extend the H decade.

Place panel on brackets in box and spot bracket holes. Remove panel and drill holes and tap with 6-32 tap. Eventually, attach panel to box with 6-32 x ¼ in. machine screws.

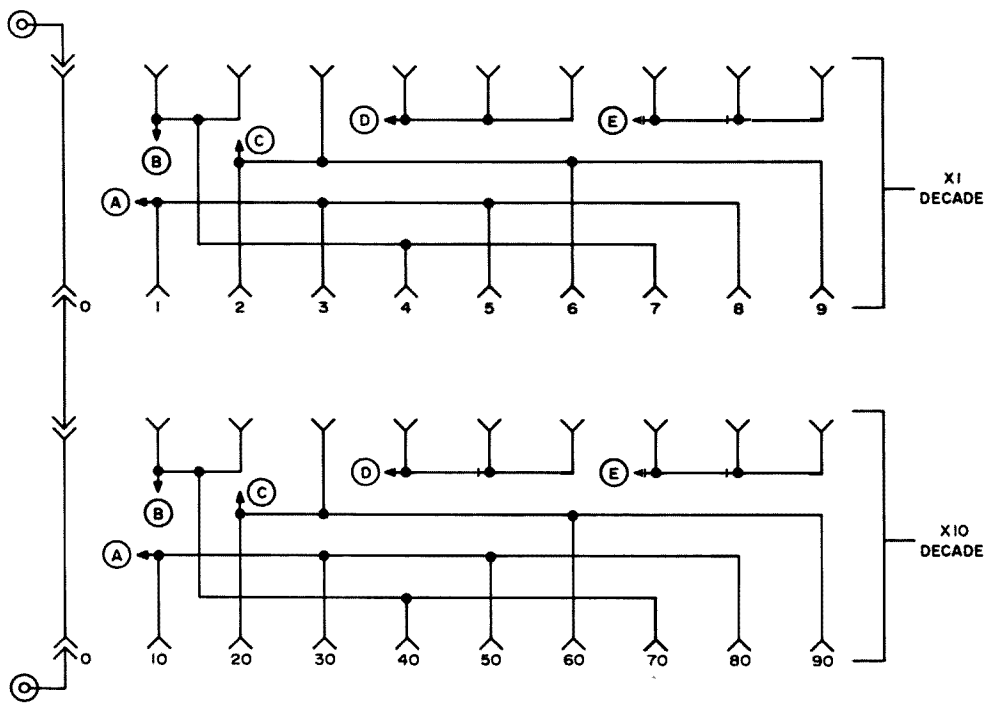
Finishing the Box

The schematic and the operating instructions should now be attached under the box and inside the lid. The box should be identified on the outside front with the name of the test equipment it houses, and the builder's call letters placed in the lower right corner.

Figure 1 shows a basic series resistance decade. It is made up of nine identical values of resistance, each of which can be calibrated to a single high-accuracy resistance. It is easy to build, as all the resistors can be soldered directly to the rotary switch. However, since it does require a greater quantity of resistors throughout, it could double the cost.

Another type of resistance decade is the H configuration of Fig. 2. This uses only four resistors mounted on a small subpanel. Note that the R1, R2, R4, and R7 values are used individually, but the other values are combinations of two resistor values. The connections are marked A to E; wires run between these points and the switching shown in Figs. 3 and 4. Figure 3 shows a dual decade resistance which uses ordinary toggle switches.

You will note that we have not talked about what the specific resistance values should be and what wattage resistors should be used. If you use composition resistors, it is suggested that 2W types be



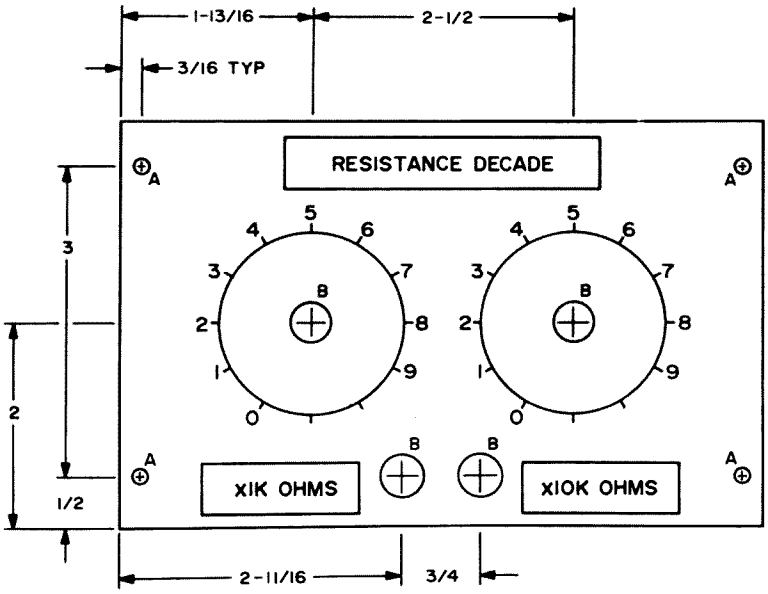


Fig. 4. Rotary switch connections for a dual decade.

HOLE CHART		
SYM	DRILL SIZE	QTY
A	NO. 25	4
B	3/8	4

Fig. 5. Panel layout for the file box unit.

used. As far as the resistance values are concerned, they will depend upon the total resistance required of the decade. For instance, a 100 kΩ decade would be composed of a 10 kΩ, 20 kΩ, 40 kΩ, and 70 kΩ.

It is suggested that you make up your first dual decade file box with 10 kΩ and 100 kΩ decades. Then build another with 100Ω and 1 kΩ decades. This should cover the largest part of the resistance requirements. Other values, of course, can be used, but watch the added circuit resistance with low decade resistances.

The second switching method for the H configuration is the rotary switch shown in Fig. 4. This is the configuration shown in the photo. A panel layout is shown in Fig. 5. The panel markings shown for the various switch positions on the panel can be accomplished with metal escutcheons, as shown, or with dry transfers such as obtained from Datamark.

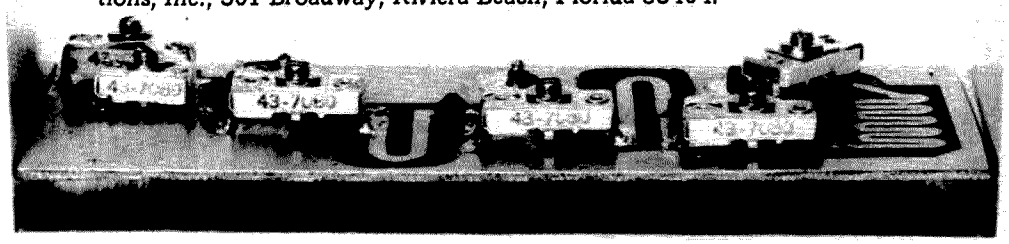
Accuracy

It is self-evident that resistors should be as precise as your pocketbook can afford. Why not start out with 5% composition resistors and when you run across more accurate values, just substitute them. One way to get the accuracy better, and by as much as an order of magnitude is to use paired resistors of twice the value, and in parallel.

If you can beg or borrow the use of a good resistance bridge, you can calibrate the resistors quite accurately by taking two resistors in parallel, and by picking the resistors, come out with rather good accuracy. First calibrate each resistor on the bridge, separating them into two piles, those plus and those minus the resistance value which is just twice the desired value. Then set the bridge to the final desired value and match plus and minus values until you get two that hit the correct value.

Just one caution: When you solder composition resistors, treat them as you would a transistor. They can permanently change value due to too high applied heat. Use a pair of pliers as a heatsink between the resistor and the hot soldered joint.

When you have installed the panel in the specially worked file box, attached the schematic to the bottom and any information, such as calibration dates and accuracies, you will have a compact, useful test instrument that can help you a great deal in your ham building.



File Box Parts List

(1) file box
(2) pieces of ½ in. aluminum bracket (4 in. lengths)
(4) rubber feet with 6-32 mounting screws and nuts

Editor's Report:
The DyComm 15W 2 Motor Mini-Amplifier

The DyComm 101—500 rf amplifier is a product of Dynamic Communications, Inc., 301 Broadway, Riviera Beach, Florida 33404.

There's a brand new miniature rf amplifier being marketed that should be of considerable interest to both builders and the QRP boys alike. The unit is small enough to fit into your pocket, and can whack out a signal of up to 15 watts with less than 80 mW of drive. For FM applications in particular the tiny amplifier should prove extremely popular. To get it going, all that is required is to apply a 12V dc power source and feed in a low-power FM signal. Then presto, a 50 mW handie-talkie becomes a full-powered mobile.

General

This sophisticated little piece of machinery is called the DyComm 101-500. It was originally developed as a module of a compact commercial radiotelephone unit, and it is currently in use in that service. Considering the fact that the rf amplifier designed for the commercial application was reliable, efficient, self-contained, and extremely broad-banded, someone got the bright idea of making the units available to amateurs.

Not that the frequency of operation can't be changed; it can – by the simple expedient of adjusting a few variable capacitors. But as it comes from the factory, the amplifier is tuned to the center of the 2 meter band. The curve of resonance is so broad that the half-power points (without tuning) are a full three megahertz either side of the center frequency.

According to the manufacturer, the DyComm's main claim to fame is its remarkable cleanness of signal. Harmonic content is so low that no feedback coupling was used in the design. This exceptional performance is partially attributable to the low-Q coupling used in the collector and base circuits between stages. With a sufficient number of stages to assure high efficiency and plenty of gain without excessive drive, each stage's input level is limited by very low-Q rf chokes The philosophy seems to be "the lower the drive, the less the chance of harmonic radiation."

The unit that was submitted to 73 for evaluation was reportedly right off the production line. All I needed was a low-power rf source and an auto battery of some other source of dc. I just happened to have an HT-100, a pocket sized transceiver made by Motorola that puts out 100 mW of rf on 2 meters FM. For power, I used an Eico 10A variable dc power supply.

Since the DyComm requires only 20 mW to drive it, I coupled the Handie-Talkie's signal into the unit with nothing more than a clip lead attached to the telescoping antenna. I connected the DyComm output through a Bird Thru-Line wattmeter to a 2 meter groundplane, hooked up the dc power, and pressed the push-to-talk switch. Immediately, the Bird indicated a power output of just under 12W. I increased the dc supply voltage to 15V and trimmed the final a bit and the output climbed to 15W.

I don't know how much rf power I was putting into the DyComm, but the manufacturer's specifications stated that the input range should be somewhere between 20 and 50 mW. I can assume I was in the general ballpark because my HT is only rated for 100 mW at best and there was bound to be a substantial signal loss because of my hokey coupling method.

The Circuit

As shown in Fig. 1, the circuit consists of three rf stages connected in cascade. The complete amplifier is built onto an epoxy–fiber-glass circuit that is nestled within the confines of a heatsink "surround." Large-signal impedance values were used in calculating input–output matching requirements, and L-type matching networks are employed in coupling. The result, according to the manufacurer, is optimum transfer of signal at the stated input and output impedances (50Ω), and maximum stability.

Another factor adding to the units' stability is the minimizing of unwanted inductances through multiple emitter contact on the driver and final transistors. The emitters in these stages are internally connected to the semiconductor case. Thus, when the transistors were inserted into the circuit board, a solder connection was made to the transistor case as well as to the emitter lead itself. This may seem like a small thing, but many engineers have gone through many hair-pulling hours trying to solve problems that could have been solved with the same simple technique.

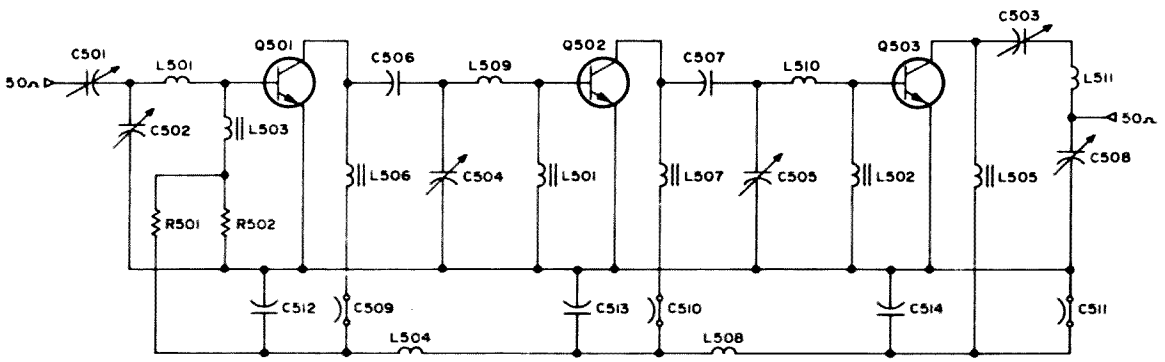

Fig. 1. Complete schematic of the DyComm 101-500 rf power amplifier. Total gain of the three-stage unit is 25–30 dB, depending on drive and supply voltage.

The overall gain of the amplifier is about 28–30 dB. The first stage gain is 12 dB; the balance is equally divided between the second and final stages. If signals greater than 20–50 mW are to be coupled into the amplifier, the first-stage gain can be reduced by lifting R502. If signals greater than 500 mW are to be amplified, the signal should be coupled directly into the second stage.

Performance

Figure 2 shows how the DyComm rf amplifier is interconnected in actual use.

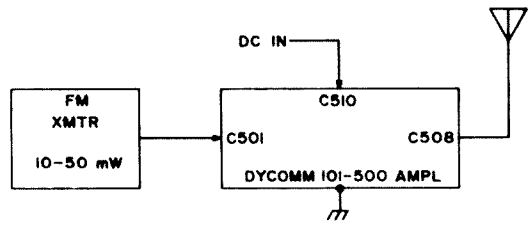

Fig. 2. This sketch shows how the DyComm rf amplifier is interconnected for operation. The capacitor numbers depicted are tie points.

Since the amplifier can be classed as a class C type, it accepts CW or FM directly. With some modification, the circuit can be linearized to accept AM signals, too; the manufacturer can supply all the information necessary to do this.

The tables below list the actual measured output power at various dc input voltages. Table I gives performance figures for an rf drive of 25 mW. Table II shows performance with 35 mW of drive.

STUDY GUIDE GENERAL CLASS LICENSE

PART IIB

In the first half of this part of the study course we determined that *resistance* and *reactance* could be considered as forms of *impedance* – which helps us understand why the ohm can be the common unit of measure.

But what about the effects of impedances, such as rf resistance, skin effect, and other resistive and inductive phenomena? In the first part of this series, we mentioned a definition of inductance based on the "number of flux lines" encircling the current flow, to show what happens.

Consider a piece of straight copper wire, such as that sketched in cross-section view in Fig. 10. (The figure numbers are continuations of those in Part IIA.)

If we push dc through this wire, from a battery, current flow will be approximately the same throughout the cross section of the wire. Just as much current will flow near the center as flows in the same cross-sectional area near the edge.

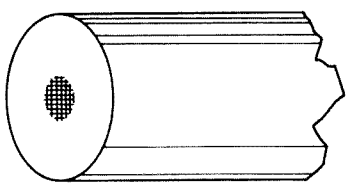

Fig. 10. Cross-section view of copper wire shows how center portion of wire is surrounded completely by conductor, while surface region has conducting material only on one side of it. This causes center to have more inductance than surface, which will in turn force ac current to seek the surface and avoid the center. The higher the frequency of the ac, the less effective will be the interior of the wire. At sufficiently high frequency, all current travels on the "skin" and almost none flows in the interior. This is called "skin effect."

That current in the center is surrounded by the magnetic field associated with itself, and also by the magnetic field associated with all the current in the outer parts of the wire, while the current on the wire's surface is surrounded by magnetic field from only itself and adjacent currents.

This means that there will be, inherently, more inductance in the center of the wire than on its surface. With dc, it makes no difference, because inductance is a factor only when current flow is changing.

With ac, the resulting inductive reactance means that the wire's impedance is lower on the surface than it is in the center. So long as signal frequency is low enough, the effects are not noticeable. At radio frequencies, though, the effect becomes appreciable. Virtually all the current is flowing near the surface of the wire, and the center might as well not be there. This variation of impedance between the surface of the conductor and its interior is what is known as "skin effect," because the rf current seems to flow on the "skin" of the conductor and avoid the interior.

No harm is done by the copper on the inside of the wire, but in high-power circuits it's often more economical to use hollow tubing rather than solid rod, and because of the skin effect one works as well as the other. It's not unheard-of to find really high-power rf coils being cooled by water pumped through the hollow cores of the conductors!

One way in which "skin effect" is minimized at moderate frequencies is by using "litz wire," which consists of many individual conductors, each insulated from the other, and woven together in such a manner that each individual conductor spends as much time in the high-inductance center of the combined strand as it does on the surface. This equalizes the inductance for all conductors, and effectively connects all of the reactances in parallel so that it does actually reduce the rf resistance. At high frequencies, however, the principle breaks down because the variation of conductor position cannot be made to happen

within a short enough distance as compared to the signal wavelength.

Litz wire, like all the other combining of reactances we've touched upon so far, involves the combination of the same type of reactance. What happens when we combine the two different types of reactance? That's our next subject.

What Is Resonance? Back near the beginning of our preceding discussion, we mentioned in passing that it was possible to use a little reactance of one kind – say inductive – to cancel out some of the other kind – in this case, capacitive.

Now let's take full advantage of this fact, with the series circuit shown in Fig. 11

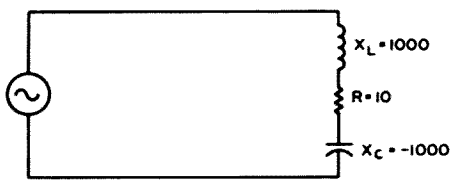

Fig. 11. Series L-C-R circuit illustrates effects of resonance, which is possibly the most important single phenomenon aside from energy propagation itself so far as radio operation is concerned. Resonance permits "tuning" of equipment to select one frequency and reject all others, which in turn makes it possible for more than one transmitter to be used at one time. Without tuning, radio as we know it would not be possible.

which contains an inductor, a capacitor, and a resistor, all in series with each other.

We know already that the resistance of the resistor will be the same at all frequencies, and that the reactances will change as the frequency changes. Let's plug in some specific figures to see how this circuit can be expected to behave. For instance, let's make the resistor 10 ohms. Reactance of the inductor will vary with frequency, being much less than 10 ohms at frequencies near zero Hz, and being in the megohm region at extremely high frequencies. Similarly, the capacitors reactance will vary from a very high value at low frequencies, to only a few ohms at high frequencies.

Notice that where the inductor's reactance is small, at the low frequencies, that of the capacitor is large, and vice versa. It stands to reason, then, that at *some* frequency within the infinite range possible, their reactance must be equal.

Let's assume that we have picked proper values for both capacitor and inductor to make this happen when the inductor's reactance is +1000 ohms; the capacitors's reactance is then -1000 ohms.

But since the reactances are equal in value and opposite in sign, they cancel each other cout completely – and the resulting circuit impedance is that of the resistor alone, or 10 + j0 ohms (10 ohms at 0°, if you prefer the single-value method of rating impedance).

This might be only mildly interesting, except that the opposite kinds of reactance both tend to keep circuit impedance high at other frequencies. Take for example the frequency which is only 1/10 that at which the values cancel at 1000 ohms each. At this new frequency, the inductance is only +100 ohms, and the capacitor is up to –10,000 ohms, which gives us a net reactance of -9,900 ohms. Circuit impedance is 10 - j9900 ohms, or in the single-value method, 9900.5 ohms at -89.5° approximately.

Going in the other direction, at the frequency 10 times that at which the values cancel, the inductance is up to +10,000 ohms and the capacitor is down to -100 ohms, which gives a circuit impedance of 10 + j9900 ohms or, in single values, 9900.5 ohms at +89.5 degrees.

If our circuit is fed by an ac source which provides the same voltage – say 99 volts – at all frequencies, then at either the high or the low frequency only about 1/100 ampere of current will flow through the circuit. But at the single frequency where the reactances cancel, current will be limited only by the resistance and in this case the current flow will be 9.9 amperes. That's 990 times as much as at either the high or the low frequency.

In this manner, the series L-C-R circuit of Fig. 11 selects current at a single specific frequency and permits it to flow through, while tending to block current at all other frequencies either higher or lower.

And that's the particular function which is necessary in order for us to be able to

choose a signal at one frequency and reject those at other frequencies. For this reason, this circuit and its close relatives are among the most fundamental circuits in all of radio.

The condition in which reactance is completely cancelled out of the circuit is known as "resonance," and a circuit in which all reactance is cancelled out in this manner is called a "resonant circuit." The particular resonant circuit shown in Fig. 11 is known as a "series resonant" circuit, because its driving source is in series with all circuit elements.

The impedance of a resonant circuit depends upon a number of factors, but they are lumped into two general headings. One is the frequency of the applied signal, and the other is the "Q" factor which we will be examining shortly. Figure 12 is a

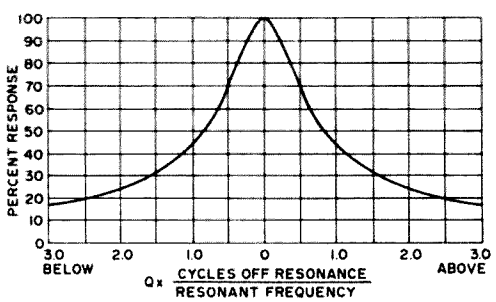

Fig. 12. Response curve of any resonant circuit is shown here. Horizontal scale is dependent upon two factors, "Q" and "resonant frequency," which makes this graph universal. For example, a resonant circuit with a Q of 100 and a resonant frequency of 10 kHz would make the horizontal scale come out to be 100/10000 times cycles off resonance, or 0.01 times cycles. At a frequency of 10.01 kHz, 100 cycles above resonance, the value to use on the horizontal scale would be 0.01 times 100 or 1.0, and response would be 45 percent of that at resonance.

graph of a "universal" resonance response curve; the solid line can be thought of as representing current flow through the circuit of Fig. 11 as compared to maximum current flow at resonance.

In addition to the series resonant circuit, we also make use of "parallel resonant" circuits. Parallel resonance was at one time called "antiresonance," but this word is rather rapidly fading from use. Figure 13 shows a parallel resonant circuit.

If we ignore the power-source connections in Fig. 13 we will see that the reactances and the resistance are still in series with each other. The difference between parallel resonant circuits and

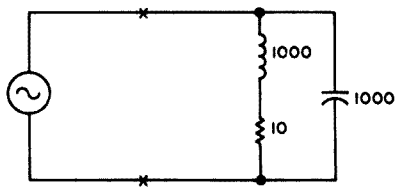

Fig. 13. Schematic of typical parallel-resonant circuit. If power source is disconnected at points marked "X" and circuit is then opened at any point, it becomes same as series-resonant circuit of Fig. 11. Resistance is shown here in series with inductor because in practice, inductors usually have more stray resistance than do capacitors and circuit behaves as if all resistance were in the inductive leg. See text for details of circuit action.

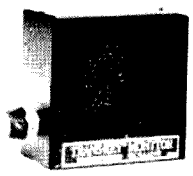
series resonant circuits depends on the way in which the power or driving source is connected. If the source is in series with the reactances, it's series resonant. If the source is in parallel, it's parallel resonance.

The impedance characteristics of a parallel-resonant circuit are markedly different from those of series resonance. In series resonance, circuit impedance is high except at the resonant frequency. In parallel resonance, though, the reactances are in parallel so far as the power source is concerned, and this means that rather than cancelling out reactances, we must combine "susceptances." High reactance means low susceptance, and vice versa.

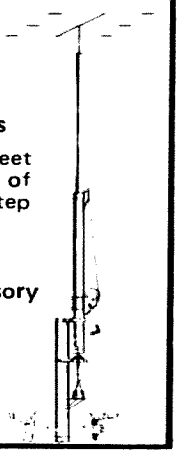
At low frequencies, the inductor has low reactance and high susceptance, while the capacitor has high reactance and low susceptance. The capacitor's low susceptance cancels out its corresponding amount of inductive susceptance, but the remaining susceptance is still high which makes net reactance low.

At high frequencies, it's just the other way around, and net reactance is still low.



At the resonant frequency, the two susceptances are equal, and so they do cancel each other out. But a susceptance of zero is equivalent to an infinite impedance. This means that at its resonant frequency, a parallel-resonant circuit must have very high impedance. At other frequencies, the impedance depends upon the reactance left over after cancellations.

Why is the impedance so high at resonance? This happens because each reactance, individually, enforces aphase shift between voltage and current. The capacitor puts voltage 90° behind current, or current 90° ahead of voltage. The inductor puts current 90° behind voltage. Since the circuit is parallel, voltage across both reactances is identical at all times. But since current in the capacitor is 90° ahead of this voltage while current in the inductor is 90° behind, the phase difference between the two currents is 180° – and this amounts to a complete cancellation of current flow.



The "cancellation" is effective only so far as the power source is concerned. In each reactance, its own current is flowing. However, this current cannot get out of the circuit – and so it circulates between inductor and capacitor. It's known as "circulating current," and is very real indeed as anyone who has watched the output coils of his transmitter melt from its effects can testify!

The circulating current is, in fact, as much *larger* than the current which either reactance alone would permit to flow, as the actual current flow is smaller. Both are related to the circuit's "Q" as we shall shortly see.

Because the circulating current *is* larger, a closed resonant circuit in which circulating current flows can act as a voltage amplifier. The circulating current through each reactance will produce a voltage drop determined by the amount of current circulating and by the reactance value. If the driving power is coupled into the circuit by means of a tap on the inductor, it can force large circulating currents, and an output voltage much larger than the input voltage can be obtained. This isn't something for nothing, because no *power*

TRANSKEY(TM)

$34.95
Postpaid
Electronic Keyer and Monitor
+Transistorized; relay output.
+Key built-in; wired, ready to operate.
+Continuously variable speeds 5-50 WPM.
+Penlight cells or 6V external source.
+Key contacts adjustable.
+Push switch on back, automatic or semi-automatic operation.
+Dot-space ratio adjustable.
+Variable tone control on monitor.
+Keyer 3½ x 5½ x 1¾. Weight 2 lbs.
+Unconditional one year guarantee.

gain is achieved. The higher voltage can only be obtained if little or no current is taken from the circuit. Many receiver input circuits make use of this fact to help overcome effects of tube and circuit noise, by stepping up signal voltage ahead of any amplifier stages.

To determine the exact frequency at which any specific pair of inductance and capacitance values will be resonant, we just combine the inductive-reactance and the capacitive-reactance formulas and come up

$$F = \frac{1}{2\pi\sqrt{LC}} \qquad F^2 = \frac{25{,}330}{LC}$$

Fig. 14. Equations for resonant circuits. Version at left is basic formula, with frequency in hertz, inductance in henries, and capacitance in farads. That at right is practical version with frequency in megahertz, inductance in microhenries, and capacitance in picofarads. For any value of inductor, some capacitor exists to make it resonant at any desired frequency. In practice, choices are also limited by effects upon circuit Q and feasibility of actually obtaining desired values.

with the equations shown in Fig. 14. As before, one is exact and the other is more practical, having all the conversion factors and the "pi" constant built into a single magic number. While any specific pair of values will have only one resonant frequency, in theory any inductor can be resonated at any desired frequency by simply choosing the proper capacitor value, and vice versa. In practice, "Q" is also a factor to be reckoned with and tends to limit the choice of L and C values.

All through this discussion we've had to refer to "Q" from time to time. Let's find out now just what this strange factor is, and what its effects are.

What Is Q? "Q" is a symbol which shows up in radio theory just about as often as do the "R" which stands for resistance, and the "E" for voltage, the "I" for current, the "L" for inductance, or the "C" of capacitance. You'll meet "Q" as part of the description of nearly any coil, many capacitors, and all tuned circuits. It is used to describe the characteristics of quartz crystals, and of antennas. But what is it?

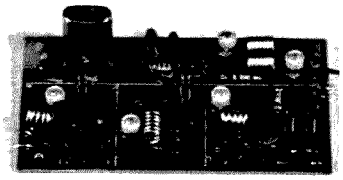
The symbol "Q" originally stood for "qualify factor," and almost all textbooks define it in the same say – as the ratio of inductive reactance to total resistance in a circuit (X_L/R). But very few texts bother to show why the ratio of reactance to resistance should be of much importance, and only a couple of the more than a dozen we studied in preparing this discussion bothered to give any other definition of Q.

Nevertheless, Q *is* important, and it has many definitions, all are equally true in every case, but for any special case, some are easier to apply than others.

So let's try to see first why the ratio X_L/R affects behavior of a resonant circuit, and then explore some alternate definitions of Q. We'll begin by returning to our series-resonant circuit shown in Fig. 11, with the same component values used before. That is, 10 ohms resistance and 1000 ohms reactance for each reactance.

We discovered already that if this circuit is driven by a power source which delivers 99 volts peak, a peak current of 9.9 amperes will flow through each of its three elements.

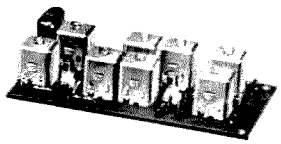
What we failed to say before is the fact that we can determine the voltage across either the coil or the capacitor alone, either by Ohm's Law or by actual measurement with a good VTVM. Here, we'll do it with Ohm's Law in the form E = IZ.



Since it's a series circuit, I is the same for all three elemtnts, or 9.9 amperes with our 99-volt source. Impedance of the coil is 1000 ohms at 90°, and so the voltage across the coil must be 9.9 times 1000, or 9,900 volts at 90°. Impedance of the capacitor is also 1000 ohms at -90°, so its voltage must be 9.900 volts also, but at -90°. Since these two high voltages are 180° out of phase with each other, they cancel each other out and cannot appear to the external circuit – but inside the circuit, measured across each element by itself, they're present.

Some authorities call this action the

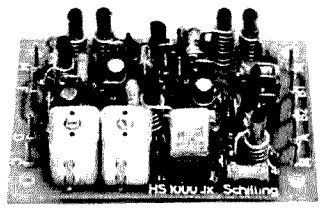
FET CONVERTER KITS FOR 50, 144 AND 220 MHZ



Basic two-meter converter described in February 1969 issue of VHF COMMUNICATIONS. The most popular VHF converter in Europe! Hundreds already in use in North America.

Kit contains: Glass-epoxy p.c. board (silverplated), crystal, coil forms and trimmers. Requires additionally: Three FET's (TIS 34, MPF 107, etc.), two bipolar transistors (TIS 45, etc.), coil wire, fixed capacitors and resistors. IF 28–32 MHz. 12 VDC/16 mA. Noise figure (attained with MPF 107's) 50 MHz: 2, 144 MHz: 2, 220 MHz: 2.5.

Kit price $10.20 each.



DUAL GATE MOSFET CONVERTERS FOR TWO METERS

Low noise figure (<2). Excellent cross modulation and image rejection (116 MHz xtal oscillator). IF 28–30 MHz. 12 VDC/20 mA. Silver-plated, glass-epoxy p.c. board. All inductors shielded. Fully assembled and aligned. By Braun.

Model DGTC 22, $35.00

Highly compact converter (3" x 2" x 1"); can be mounted in existing receiver or transceiver cabinet. Electrical characteristics as above, except any IF between 14 and 32 MHz can be selected by simple plug-in of the appropriate oscillator crystal. (116 MHz crystal furnished with converter). Oscillator-emitter follower output for use with transceiver.

Schilling Model HS 1000 Jx, $ 39.50

"voltage magnification" of the resonant circuit, and speak of the 9900/99 ratio between reactive voltage and applied voltage as the "magnification factor."

Others call the ratio the "quality factor" or merely "Q."

The relation between this "magnification factor" and the definition of Q as being X_L/R is not overly obvious. It comes about because each of the voltages – that across the reactance and that across the total circuit – is related to the same series current by Ohm's Law. In both cases, E = IZ, where Z is the impedance and I is the current.

For the reactance, the Z is equal to X_L or X_C, and at resonance they're the same absolute value. For the total circuit, both reactances cancel out and the impedance is simply R. The voltage ratio E_x/E_t then becomes IX_L/IR; the I cancels out of the calculation since I/I is always "1," leaving us only X_L/R to define the magnification factor or Q.

Now let's see why "Q" should be such an important factor in the first place.

One of the most important uses of "Q" is as a measure of the effectiveness of a resonant circuit. That is, it measures how effectively the circuit can separate two signals of different frequency. We can demonstrate the relation between Q and selectivity in two ways, one of which is easy to see and the other of which, though much more accurate, requires more thought. Let's try both, the simpler one first.

Recall that the selection capability of a series resonant circuit comes about because at the resonant frequency, current flow is limited only by the R of the circuit, while at frequencies far from resonance, the X is the limiting factor and the R has very little effect.

This means that if the resistance is very small compared to the reactance at the resonant frequency, the current flow at resonance will be very high compared to current at those frequencies where the reactance is the limiting factor.

If we increase the resistance and leave reactance alone, it will have little effect on current at the extreme frequencies, but will

reduce the current flow at resonance. Thus the ratio between current at resonance and current far from resonance will become smaller, and the circuit is therefore less selescive.

Since Q goes down as resistance goes up, if X is constant, this means that a high-Q circuit must be more selective than one with low Q.

While this explanation shows how circuit Q affects selectivity in general, it unfortunately does not tell us much about what happens at frequencies near resonance. To find out how Q works in this region – which, after all, is the one in which we are most often really interested – we must go to the more detailed explanation. It takes a little arithmetic to illustrate.

We define Q by looking at the "magnification factor" – the ratio between the voltage across either reactance, and the total voltage applied to the circuit.

At frequencies near resonance, the reactances will not vary greatly from their values at resonance. If our inductor has 1000 ohms reactance at 10,000 Hz, then at 10,010 Hz its reactance will be 1001 ohms, and at 9,090 Hz it will be 999 ohms. The capacitor will behave similarly, with reactance values of -999 ohms at 10,010 Hz and -1001 ohms at 9,090 Hz.

Because of the mutual cancellation of opposite types of reactance, the net reactance of the circuit will be the difference in reactance values. At 10,010 Hz, net circuit reactance would be 1001 - 999, or 2 ohms inductive.

If our circuit had a Q of 100, this would mean a resistance of 10 ohms (and with a 100-volt-peak source, 10 amperes current flow at resonance). Impedance of the circuit at 10,010 Hz, then, would be 10 + j2 ohms, or about 10.19 ohms at a very small phase angle. Current flow at this frequency (E/Z) would be 100/10.19 or about 9.84 amperes, nearly as much as the 10 amperes at resonance.

If we leave the reactances alone, but reduce the resistance to only 2 ohms, we will raise circuit Q to 500 (1000/2). Current flow at resonance would be 5 times as great, or 50 amperes with a 100-volt source. At 10,010 Hz, however, circuit impedance would not be 2 + j2 ohms, or 2.83 ohms at 45°. Current at this frequency would be 100/2.83 or 35.4 amperes. This is only 35.4/50 or 70.8% of the current at resonance, while with a Q of 100 the currents at the two frequencies were almost equal.

The same thing happens at all other frequencies, whether near to or far from the resonance point of the circuit. The result is that a high-Q circuit is "sharper" than one of low Q. Figure 15 shows this by

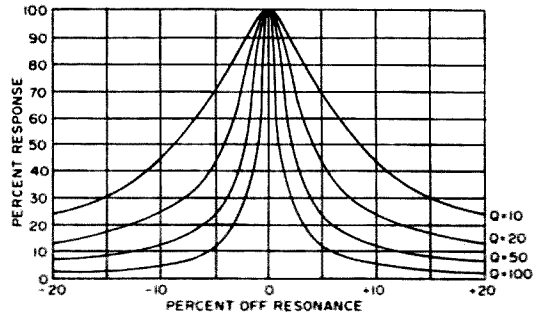

Fig. 15. Effect of Q upon circuit selectivity is shown graphically. This is similar to Fig. 12, except that factor "Q" has been removed from horizontal scale and different curves have been drawn for different Q values. The greater the Q, the sharper the selectivity. Notice that effects are greatest in regions near resonance, but very little difference exists at frequencies almost exactly on the resonant frequency.

comparing relative currents for circuits with Q's ranging from 10 to 100, for frequencies from 20 percent below resonance to 20 percent above.

Of course, instead of measuring current flow through the circuit directly, we could take the voltage developed across either reactance, because this voltage is developed by the current flow through that reactance. And, in practice, this is exactly the way in which a receiver makes use of resonant circuits. The output of the circuit is usually the voltage developed across the capacitor.

The ratio X_L/R is the most commonly encountered definition for Q, but it's not by any means the only one nor is it even the most descriptive. Our own favorite is

one which defined Q as being proportional to "the ratio of peak energy storage to average power loss" in any circuit.

This definition is directly related to the more familiar one, because the circuit's reactance is a measure of peak energy storage while the resistance includes any factors which actually *lose* energy.

However, thinking of Q as a ratio of energy stored to energy lost makes it apply to many non-electrical things, such as a swinging pendulum or a vibrating tuning fork, while the terms "reactance" and "resistance" are limited by definition to electrical actions.

Q is sometimes defined as being the inverse (or reciprocal) of the "power factor" of a component or circuit. The "power factor" is the ratio of power consumed to apparent power, which boils down to being a ratio of resistance to reactance. Since this is the inverse of the ratio which defines Q in the most common definition, defining Q as the inverse of power factor is simply a second-hand way of providing the same definition.

Q is also sometimes defined – and frequently measured – by its effect on bandwidth of a circuit. In resonant circuits having Q's in the normal range (from 10 to 1000,) the number of Hz between the half-power points (the two frequencies, one above and one below the resonant frequency, at which power transfer falls to half of that transmitted at resonance) are related to the resonant frequency by a factor which is roughly 1/Q.

That is, for a Q of 10, the lower half-power point will be f/10 Hz below the upper one, if "f" is the resonant frequency in Hz. If Q is raised to 20, the separation or "bandwidth" will be f/20 Hz, and with a Q of 100, it will be f/100 Hz.

All of our discussion of "Q" so far has been in terms of series resonant circuits. It applies equally, though, to parallel-resonant circuits by making proper substitutions. The net result after these substitutions are made is that the circuit impedance, rather than voltage, is multiplied by Q. That is, in a parallel-resonant circuit each of whose reactances is 1000 ohms at resonance and having a Q of 100, the impedance at resonance will be 100,000 ohms at 0°.

If such a circuit is then "loaded" by connecting a perfect 100,000-ohm resistor across it, the net impedance will be reduced to 50,000 ohms. The same result would be produced by raising the internal resistance from 10 to 20 ohms and so lowering Q to 50. In most radio theory the effects of such "loading" are accounted for by assuming that the load is "transformed" into the equivalent series resistance. In this case, the 100,000 ohm resistor's value would be transformed to 10 ohms, and its effective connection point would be changed from being in parallel with the resonant circuit to being in series with the inductor inside the circuit.

This is what is meant by the "impedance transformation" effects of a tuned circuit, and transmitters make use of tuned circuits in this way to large degree.

We said way back at the beginning of this discussion that Q is applied to such things as quartz crystals and antennas, as well as to conventional resonant circuits. In these cases, the "energy stored/energy lost" definition is the most meaningful one.

A crystal, for instance, will vibrate for some time after receiving a single impulse, and this vibration will in turn return electrical energy in the form of mechanical vibrations and returns it with little loss. This means that the "Q" of a crystal is remarkably high (around 25,000 for most ham units).

An antenna, on the other hand, is intended to radiate or lose as much energy as possible, so that low Q is desirable for any antenna. Many designs, however, will radiate effectively only over a narrow range of frequencies, and at all other frequencies will store the energy rather than radiating it. This means that the Q goes up, and the designer must find ways of lowering the antenna Q.

Next Time. Now that we have fairly firm foundations established both for ac and dc circuit theory, we can go into the superstructure. Our next installment will examine power, decibels, and harmonics.

. . . Staff ■

What Really Happened To Hamdom?

Robert M. Brown W9HBF
5611 Middaugh Avenue
Downers Grove IL 60515

Incentive programs or not, this article is hardly expected to endear the writer to the hams in this country—nor, perhaps, to the policy-making editors of *73*. It is designed instead to inform hamdom of some serious problems that have been all but ignored in recent years. Let it be stated now that what follows are the impressions and opinions of the author, combined with known facts gleaned from the general public, the electronic industry, and from current legislation and trends in Washington, D.C.

We challenge readers to dispute these truths; we implore readers to reexamine themselves and make an honest effort towards maintaining the open-mindedness this hobby needs.

The draft for this diatribe began as an article devoted to informing our meager readership of the pros and cons of QRP. Before I realized, however, I had struck a tender root of one of the most serious problems American amateurs face today. But we are getting ahead of our story.

In an attempt to get a truly objective perspective regarding the state of ham radio today, I stumbled across an item of profound implication in the foreign ham press. Smatterings of information on low-power and QRP associations have appeared from time to time in the recent past in this country, but there remains the fact that a great deal of amateurs here don't even know what QRP means, much less the thinking behind it. So what?

Shortly after the last war, amateurs in almost all other countries began to seriously investigate the advantages of running on reduced power. In London the QRP Society, Inc., was formed to keep Europeans abreast of flea-power military surplus bargains while at the same time serving to further awaken hamdom to the exciting world of QRP. What caused this interest in "half-hearted" hamming? Economics. The flow of surplus equipment into European markets meant that with the proper knowledge, an SWL could get on the air without investing large sums of

money. In short, the expense of becoming a ham had been substantially lowered, and with it came a remarkable increase in the number of foreign amateurs on the air. Understanding this important factor, it is relatively simple to see why the QRP trend caught on like wild fire overseas.

While progressive European countries experimented with single-tube transmitters and later developed transistorized 144 MHz transceivers, Americans built kilowatts. Today the foreign journals referred to earlier, such as the *RSGB Bulletin, Das DL-QTC,* and *UKW Berichte*, carry an amazing array of flea-power projects surrounded by advertisements offering transistorized low-frequency and UHF stations. Our magazines, on the other hand, are saturated with linear amplifiers and 2000-watt band blasters, while our advertising seems to cater to the conventional big-station buyer. Somehow we have adopted the mistaken idea that power is everything.

The real truth of the matter, though, is that the American ham is generally in a better economic situation than his European comrades. He can afford the "best." Ham radio in this country has clearly degenerated to the point where status in many circles is determined by income. Not so?

A good example is found at six meters, a band that this writer feels more than qualified to talk about. Rather than generate interest in experimenting with narrowband FM, sideband techniques, and almost interference-free CW, the 50 MHz band is presently presided upon by the DX-happy. Who can snag the most states? When will Puerto Rico slip in again to be pounced upon by 912 East or West Coast snoopers? And they are almost all doing it with AM phone. Nobody builds here anymore. It "isn't necessary." Others feel that "commercial competition has made it cheaper to buy 6 meter rigs." Hogwash. Of course I'm not talking about the dedicated Technicians who are there for legitimate reasons; I'm calling out the 85% whose goal is to buy bigger and better equipment as they can afford it. Naturally, with a philosophy like this prevailing on a ham band, newcomers are apt to feel that unless they can afford to buy the best they just won't be "in it." And the sad truth is that they aren't.

Smashing the Price Barrier

So fervent is the struggle for power on the ham bands today that thousands do not realize just how little they are buying for the hard-earned dollar. The real difference between 75W and a full gallon is inconsequential when compared open-mindedly to the economic ratio of either building or purchasing a three-element beam to replace a folded dipole. Or when compared to spending even one-quarter that amount for a good preselector or Q-multiplier.

Communications – *true* communications – is an art. If DX is your forte, working stations others can't even hear should prove extremely exciting. Yet I'll wager you could do it by properly investing but a fraction of what you have already spent into refined necessities. Don Stoner W6TNS has WAC on 15 CW running 80 milliwatts. ZL1AAX works regularly into the states with 20 milliwatts. K1CRD in Connecticut sets his own 50 MHz records using but a 27 milliwatt transceiver he built from combining various transistor circuits in current electronics journals. Interested?

Offering an answer to the long-standing price barrier facing even American amateurs, the transition to QRP is just beginning to catch. And to the avid exponents of the sport, a challenge is there to be delved into, examined and explored to the hilt. What is there for people interested in flea-power today?

Plenty. Although the London QRP Society folded in the early fifties, in something short of four years the new QRP Amateur Radio Club (headed by K8DZR in Ohio) has snowballed into one of ham radio's largest fraternities. With members all over the world, the QRP ARC sponsors contests, proves the truths of low-power hamming every day, and publishes a handsome quarterly brimming with interesting case histories and construction projects.

Since the high power stigma has begun to alleviate, QRP'ers are striving for cheaper and cheaper rigs. QRP ARC chap-

ters offer prizes for the best units built for under $10. Now circulating are circuits for low-frequency receivers (less than $4) and AM transmitters for 20 meters (perhaps $12). And then there are all those slightly used CB transceivers that can be modified by a child for 10 meters. . .very cheaply. And I could go on and on.

The Ugly American

But by and large, high power still has a long way to go before it is completely abolished. As long as the law says Americans can run 1kW input to the final, even though most foreigners are restricted to under 100W, the DX man's toy will remain. What happens?

In all truth, the amateur's status symbol is his cherished homebrew gallon, more often than not a brilliantly conceived jumble of war surplus tubes and a power supply capable of pumping at least a thousand watts to the final. With a gleam in his eye the operator seeks out his prey (frequently a poor Belgian with 40W), zeros in for the kill and then, along with 74 others, calls him frantically. Silence follows. If I only had more power, our friend thinks to himself. But alas, he came back to an Englishman.

With the staggering number of postwar hams that put signals on the air as amateur radio developed into a modern-day mania, the high-power struggle seems to have intensified. By 1958 literally hundreds of illegal *California Kilowatts* were relieved of their licenses for power levels often up to 5kW and beyond.

What have we really accomplished in this high-power battle? Presently the supposedly sophisticated U.S. hams have literally saturated the spectrum, clobbering each other and the rest of the world as they swish their vfo's to clear the frequency before kicking in the linear. We have out-populated our allotted frequency space 25 years earlier than the best authorities estimated just a few decades ago. We have imposed American-made pandemonium on the worldwide DX bands.

German hams can't hold decent conversations with the English because some operator in Tuscaloosa is using his kilowatt to talk to New York. Frequency allocations being what they are, *more power means more QRM!*

The status-seeking "Ugly American" is heard round the world – regardless of whether or not anyone *wants* to listen. Today a good number of foreign hams have decided not to QSO the states and to ignore as best they can the innocuous U.S. kilowatts. Own up to it or not, a ham radio "cold war" is on. The cause: the power-mad DX-happy American ham.

Some Day We'll Pay the Penalty

The time is rapidly approaching when the rest of the ham world will have a substantial voice in declaring what the U.S. hams can and cannot do. Or to put in more bluntly, a growing number of previously friendly countries are fed up. They want to return amateur radio to the pioneer spirit that once led the art.

We have, admittedly unknowing, stepped on a great deal of tradition, destroying in our path to bigger and better things the very foundation of what the rest of the world still clings to in its interpretation of amateur radio. We can expect the worse, and accept (without further embarrassing ourselves by stupid on-the-air remarks) whatever Geneva comes up with.

The Horrible Truth About CB

Ask your typical coworker at the office what he thinks of when he visualizes a ham radio operator. Chances are he vaguely remembers visiting a boyhood friend who demonstrated his rig, talking gibberish to Rangoon while the coworker looked on fearfully at his homebrew monster flickering in its chassis.

Or more realistically, he remembers last Saturday night, when Lawrence Welk was all but obliterated by the youngster next door.

The point is simply that the impression is not good. Ask a friend the difference between a ham and a CB'er and he'll reply with the best of intentions that the ham uses radio as a toy, whereas the CB'er has a definite purpose in putting his set on the air. The public is not aware of the fact that we are supposed to be technically better informed than the CB'er.

The horrible truth is that we *are* competing with the CB'ers whether we want to

recognize it or not. The same legislative body that gave experimenters frequencies they could use for furthering the art awarded a mere 250 kHz of the 11 meter band to citizens. And what have they done with it?

To be perfectly frank, the accomplishments of CB fall just short of miraculous and something hams will have to reckon with sooner or later. Putting aside the reams of anit-CB material we publish (the more opinionated referring to them as morons*), we should at least admit the facts:

- There are literally thousands of CB clubs throughout the country cooperating with local officials to aid in emergencies.
- The press has treated CB most favorably, publicizing in newspapers and magazines the strength and power they have added to ambulance squads, police departments and highway patrols.
- The public is not plagued by nearly so much CB TVI as we would like to believe. Improvements in equipment design and the 5W power limitation do much to hold this down.
- In numbers, CB'ers are expected to top one million this year.
- Sales of CB equipment hit $54 million in 1966.
- CB offers more to the public (tangibly, at least) than amateur radio.
- America now has an emergency radio force of citizens exceeding that anywhere on earth at this time.
- At least 70% of CB units are installed for "emergency power" – under the dash.
- Detroit's leading automobile manufacturers appear anxious to arrange for CB as optional equipment in the near future.
- The FCC has already given the go-ahead for a mass program for an automobile emergency corps on CB channel 9, and has restricted channel 9 for emergency use only.
- CB can be effectively and profitably used in business – whereas ham radio cannot.

Like it or not, the above points are cold, hard facts. And they are darned tough to argue with.

So who cares about CB? Every amateur should be vitally interested in all that occurs on 27 MHz if he values his hobby. In the learned eyes of the electronics industry, the FCC and the general public, CB is accomplishing the very thing that amateur radio was founded to do.

A great number of us are under the dangerous misconception that amateur radio is primarily an exciting hobby, offering something that can be found no where else. The sad truth is that this is but a byproduct. To quote the FCC in an age-old phrase: *"Amateur radio exists because of the service it renders."* And exactly what service *do* we render that CB does not?

We spend a great deal of our time studying award requirements and calling directional CQs. We pride ourselves additionally in keeping abreast of advances in electronic communications. We try to outguess the experts by coming up with new ideas and effective techniques that the country can use. We are constantly building and improving in an effort to develop ourselves as communications specialists, or amateur engineers, as it were. We admit only the scientifically minded and those eager to learn more about electronics. Or do we? Are we really as technically advanced *individually* as our forebears? Can we honestly state that we have superior motives that will help America stay ahead technologically in the electronics race? *Can we?*

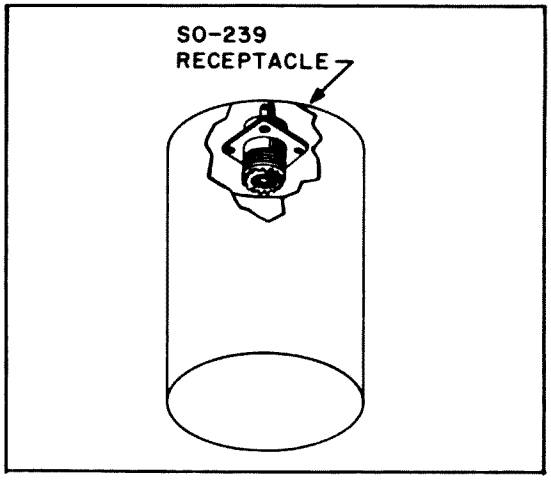
BREW 1 on 2
A TWO METER COAXIAL

It was an ordinary Saturday afternoon, as I sat in my garage hamshack drinking a cold brew. What I needed was a good 2 meter antenna. With one sterling qualification: it must be cheap, cheap, inexpensive. I rolled the brew can around in my hands and the idea struck me – why not make a coaxial antenna with the empty beer cans; I'd heard of beer can verticals – why not a beer can coaxial?

So, I broke out the ruler and found that four empty beer cans measured just over 19 in. With haste, I dug out the soldering gun, solder, and tin snips. First, I cut the tops and bottoms out with a can opener (I left the bottom in one and drilled it to accommodate an SO-239 connector). (See Fig. 1.) When this was completed, I made up a piece of coax (RG-59 or RG-9) 38 in. long with a PL-259 at each end. I connected one end to the SO-239 on the top can. This was easy at this point, but would be practically impossible later.



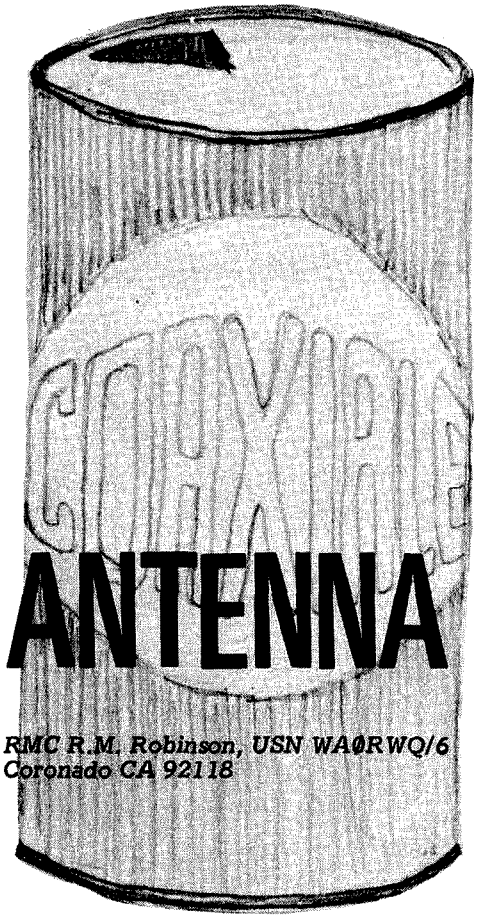


Fig. 1. Cutaway view of top can shows SO-239 inside can. The transmission line will have to be connected before the connector is attached, unless you have very, very small hands.

Then I slid that piece of coax through the center of the remaining three cans and soldered all four as shown in Fig. 2. I used a piece of 19 in. stiff wire for the radiator, and soldered it to the end of the SO-239 sticking out of the top can. If you duplicate the antenna, you'll find welding rod, coathangers, etc. quite satisfactory. Mounting is up to the builder; also, I would suggest spraying the cans with antirust

RMC R.M. Robinson, USN WAØRWQ/6
Coronado CA 92118

paint. I mounted my antenna on an old broomstick with electrical tape. Swr can be changed by shortening or lengthening the 19 in. vertical.

To trim the antenna, it is better to bend the top over a bit at a time rather than cutting it. This is so that when you pass resonance your vertical won't be too short, and you can straighten out the bent portion, rather than to have to replace it.

I used a Heathkit Twoer with about 2W output. Swr at resonance was about 1.2:1 at 145.5 MHz. I found it was quite broad, QSYing nicely without a drastic increase in swr. My antenna is about 20 ft off the ground and about 4 ft from the roof on its broomstick mast.

My first contact was with WB6YO1 in Fallbrook, Calif., about 25 miles away. I also noticed I could receive stations I never could hear before, and those I could hear were much stronger than on my old groundplane. Not bad for two hours work and no cash outlay.

I won't go into the problems associated with trying to solder aluminum. If the brew you drink comes only in aluminum cans, you'd better be good at silver-soldering; otherwise it might be wise for you to change brands for one evening.

. . . WAØRWQ ■

CONVERTING 24V DC RELAYS to 115V AC

Alan Douglas
Box 225
Pocasset MA 02559

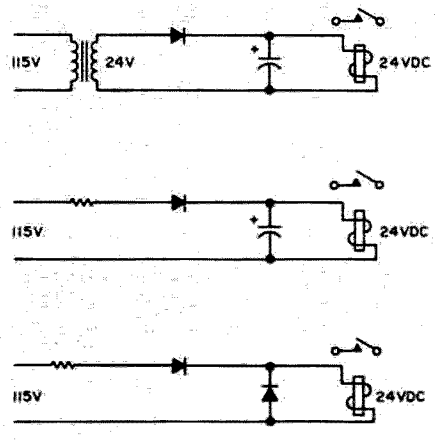
How often have you pawed through your shoebox of surplus 24V dc relays, looking for something for a 115V project, and wished you could change them over with a wave of your magic wand? Well, it's almost that simple; nearly any such relay will operate on 115V with the addition of two diodes and a resistor. And how many 48V telephone relays have you salted away, waiting to build a 48V power source to run them? They are even simpler to use; all it takes is a pair of diodes.

The classic circuit for getting 24V dc consists of a transformer, rectifier, and filter capacitor (Fig. 1). You can simplify this a little by replacing the transformer with a dropping resistor, providing you increase the capacitor's voltage rating to 150V, since without a load the voltage would rise to that value. If you have used this circuit before, you know that the capacitor is at least twice the size of the relay, and probably as expensive.

Now throw away the filter capacitor, and replace it with a diode. Filtering is provided by the inductance of the relay coil, instead of by the capacitor. To simplify basic theory, an inductor will try to keep steady the current flowing through it. If half-wave-rectified ac is applied, current flows in short bursts of 60 per second; in a relay it causes the familiar 60 Hz buzz. The diode provides a path for the current to flow between ac cycles, so that the coil current remains fairly steady, instead of being cut off abruptly 60 times a second.

This circuit works fine with most surplus relays which have a high coil inductance. The newer "crystal can" miniature relays are about the only exceptions. The 48V telephone relays are a snap to use because only a very small dropping resistor, or none at all, will operate them. Note that since the relay will tend to hold on after the power is removed, it cannot be operated as fast as a conventional relay. This is likely to cause trouble only in a keyer circuit.

No additional arc suppression is needed, since the shunt diode eliminates the transient voltages normally produced when a relay is turned off. This is, in fact, a very common arc-suppression arrangement in conventional dc circuits.



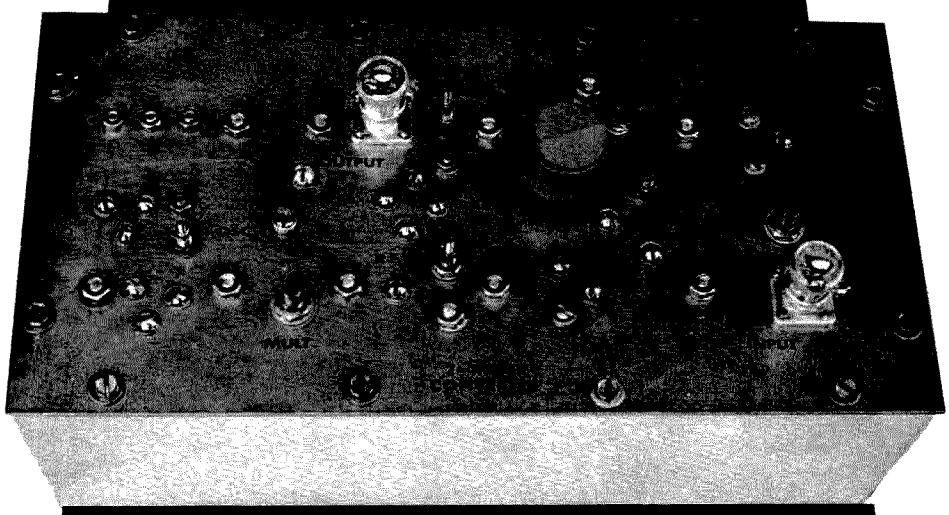


Fig. 1. In these three circuits, the result is the same. Circuit C is the simplest, though, with just one resistor and two diodes. Diode ratings should be at least one-half the relay coil current, and 200 PIV. The dropping resistor should be equal to the relay coil resistance.

Now, rush to your nearest surplus dealer and pick up a supply of relays before he reads this and ups his prices.

A VERSATILE and STABLE MOSFET CONVERTER for 144 MHz

Here is a converter which offers just about the optimum in tube and solid-state performance. Its characteristics include the following.

- Low noise figure.
- Excellent cross-modulation performance, dynamic range, and overload control.
- No neutralization, stagger-tuning, or reduced gain operation is required to prevent rf oscillations.
- Complete stability. The rf stages of this converter have never oscillated under any conditions of tuning or antenna source impedance. In addition, the local oscillator has high amplitude stability and has never required any readjustments.
- High gain with a very effective rf gain control.
- Wide bandwidth, which allows operation over the entire 144–148 MHz range with no repeaking of the converter required.

Circuit Description

The dual-gate MOSFET appears to be the new darling of the front-end designers.

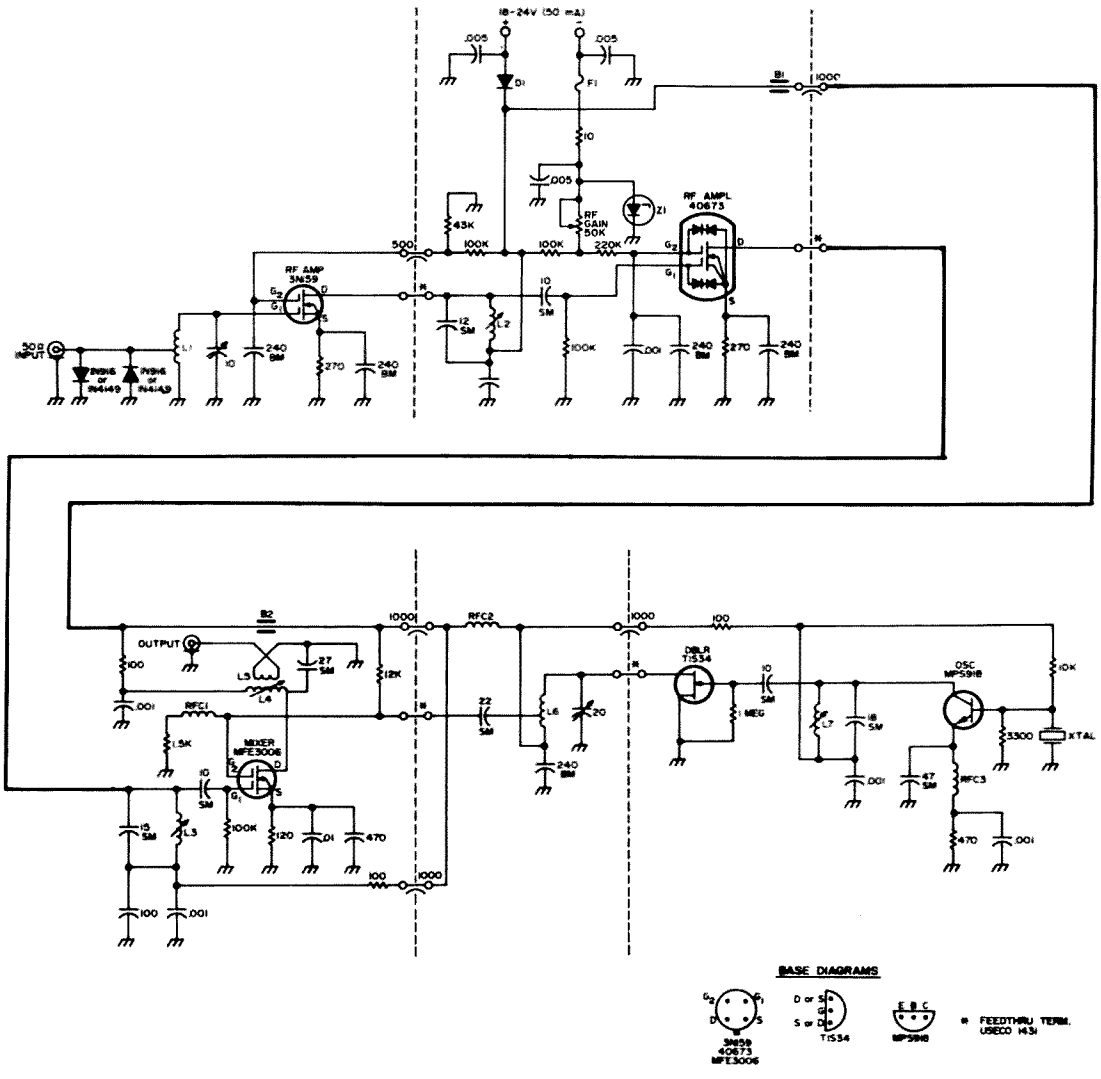

Fig. 1. Schematic diagram of the converter. Any one of the MOSFET types 3N140, 3N159, or MFE3007 may be substituted for any of the MOSFETs in the schematic. However, a 3N159 will give the lowest noise figure in the first stage. A 40673 should give the best protection against any rf spikes in the second stage. And a MFE3006/MFE3007 should give the best protection against steady, high-voltage rf signals in the mixer stage. All resistors are ½-watt carbon, 5%. All fixed capacitors other than SM, BM, or feedthrough types are disk ceramic.

It has surpassed the performance of tubes, bipolar transistors, and junction FETs with but one exception. This exception is that the junction FET gives about a 1 dB lower noise figure in the VHF range. This extra decibel of sensitivity may be useful to moonbouncers and those who live in remote areas, but if you live near populated areas, the sensitivity of the MOSFET is more than adequate to get you down into the atmosphere noise.

An important advantage of the dual-gate MOSFET is that, unlike the "triode" transistors, it does not require neutralization. Of course, if the builder uses second-rate shielding and bypassing techniques, even the dual-gate MOSFET will oscillate.

They key to the stability of the new present converter is that the rf MOSFET gate 2 source leads are soldered directly to button mica bypass capacitors. In addition, there are shields between each stage, and the rf MOSFET drain leads are soldered directly to the shield feedthroughs. Something to remember is that the series-resonant frequency of a bypass capacitor

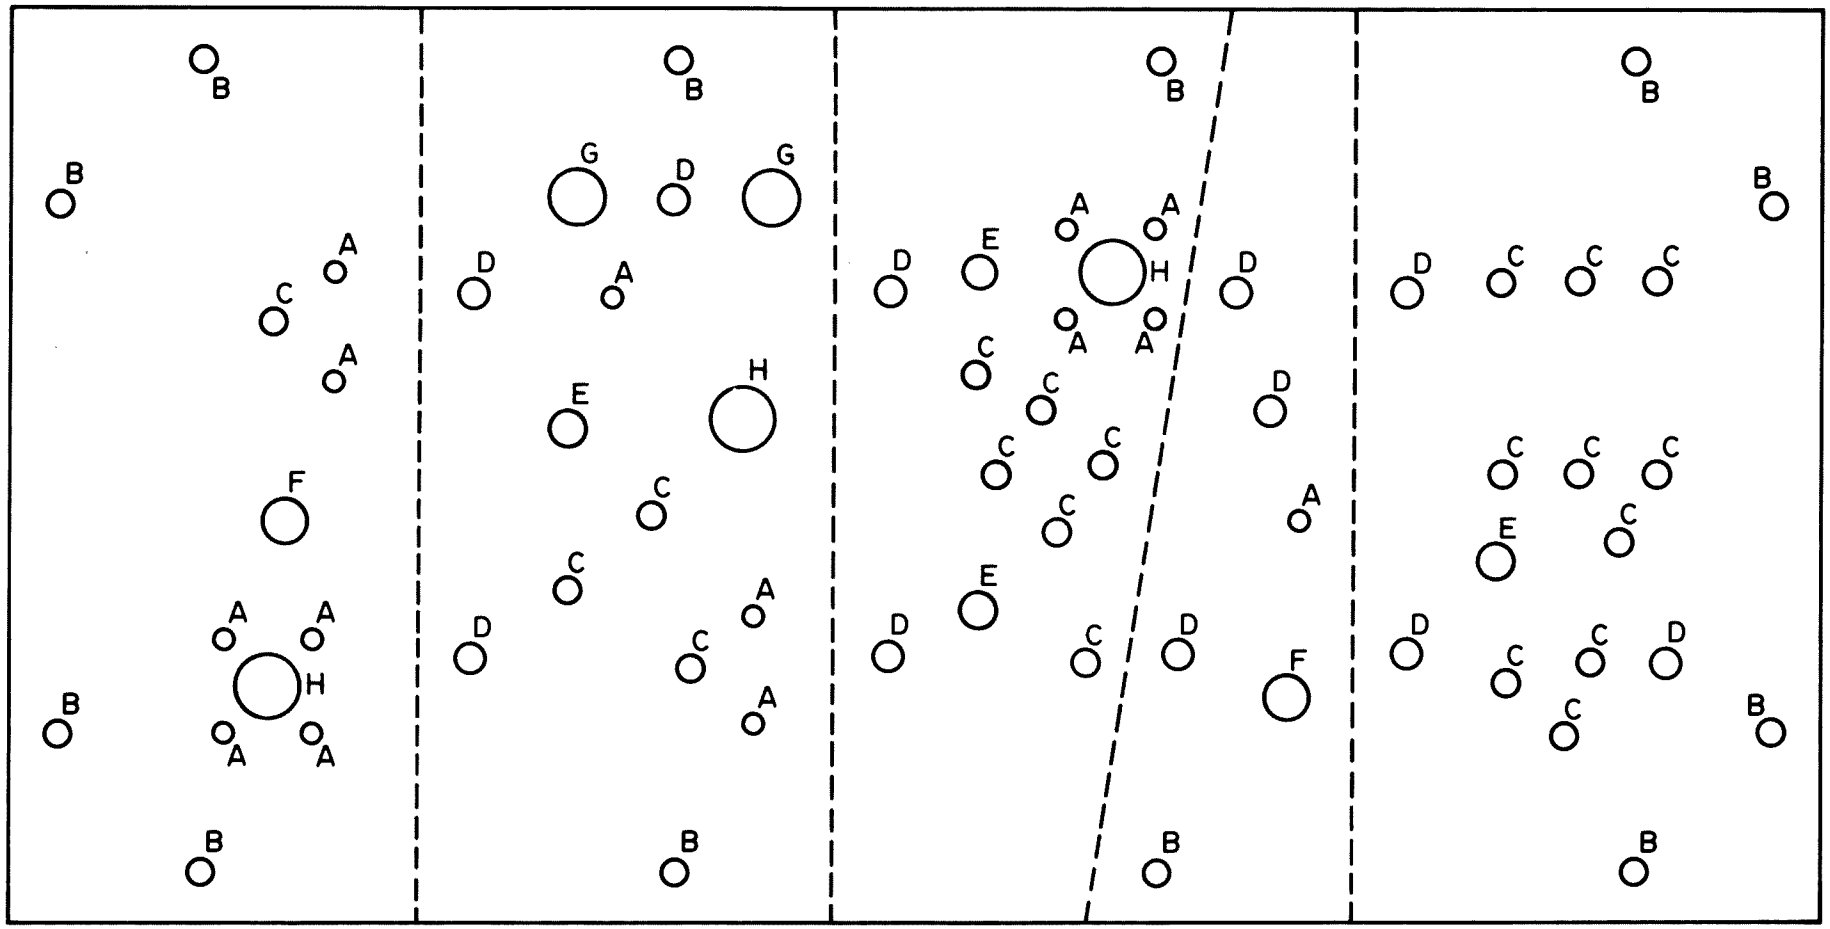

Fig. 2. Reduced-size template of chassis plate (bottom view) shows hole size and placement. The letters indicate drill sizes: A—No. 37, B—5/32 in., C—No. 26, D—No. 17, E—3/16 in., F—¼ in., G—5/16 in., H—3/8 in. The broken lines represent shielding.

should equal or exceed the frequency to be bypassed.

Figure 1 shows the converter circuit. The first rf stage uses an RCA 3N159. At the time of this writing, this transistor has the lowest 200 MHz noise figure of all dual-gate MOSFETs on the market. This stage is biased to run at "wide-open" gain for best sensitivity. The input tank has a fairly wide bandwidth so that a low noise figure is maintained over the entire 144–148 MHz band with no repeaking of the converter.

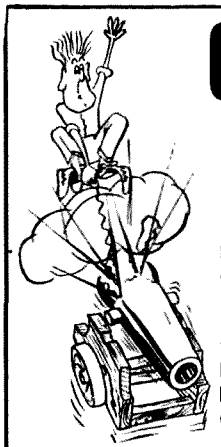
Silicon high-speed diodes are used at the antenna input. These diodes have a negligible effect on the input circuit. Germanium diodes conduct at about 0.1V so that signals above this value will be distorted. Silicon diodes, on the other hand, conduct at about 0.5V. The MOSFET, with its insulated gate, has a higher gate voltage tolerance than the J-FET whose gate will conduct at 10.5V bias. As a result, the silicon diode–MOSFET input has considerably greater overload tolerance than the germanium diode–J-FET input combination. For extreme overloads, each silicon diode may be replaced by two silicon diodes in series.

The second rf stage uses an RCA 40673. This MOSFET has integrated back-to-back diodes from each gate to the source. These diodes protect the silicon dioxide insulation from breakdown by the high-voltage spikes of static discharge. Unlike unprotected MOSFETs, these transistors require no special handling techniques.

The linear pot and 4.7V zener network provides an adjustable gain range of about 50 dB from full on to full off. The 100 kΩ resistor connected to the pot provides a gate 2 voltage of about 1V at maximum gain. This 100 kΩ may be reduced to give a higher bias and a slightly higher maximum gain but the gain control action may become more abrupt and possibly bothersome.

If the converter is to be used with a good antenna and high-gain receiver, one rf stage probably will provide adequate performance. If desired, the gain control could be applied to the first stage. To avoid parasitic oscillations, it is important to

DUAL GATE MOSFET
PRE-AMPS



to 175 MHz. **$21.95** ppd.
to 300 MHz. **$25.95** ppd.

NEW FOR 1970!
The above models now have rf gain control.
For 300 to 470 MHz
See Model 202 in our catalog.

- Available from 5 MHz. to 450 MHz. Bandwidth is approximately 3% of frequency.
- Voltage gain 30 to 40 DB depending on frequency.
- Two Dual Gate MOSFET amplifier stages with each having a tuned input and tuned output. Each Dual Gate MOSFET is actually an integrated cascode circuit thus giving you 2 cascode circuits equivalent to 4 triodes.
- Exceptionally low noise (2.5 DB at 175MHz.), greatly reduced cross modulation and 10 times the dynamic range (signal handling capability) of the best bi-polar transistors. Also superior to preamps using junction FETs and Single Gate MOSFETs.
- Internal connections for high impedance AGC or manual gain control if needed.
- Type BNC input and output receptacles for minimum loss at UHF. Standard impedance is 50-75 ohms.
- Carefully tuned at our laboratory with sweep generator and oscilloscope for the best bandpass characteristic.
- Full wave UHF diodes protect input transistor.
- Operates on 6 to 16 volts DC, 5 to 15 Ma.

New York City and State residents add local sales tax.

GUNSMOKE?

Blow your mind on our back issue bargain bunch, 30 (count 'em) assorted (we hope) back issues, all before 1968, for the incredibly low price of $6 postpaid (hardly pays for the postage). These are packed by slave labor (to cut costs) so please ignore notes calling for help, etc. that may be slipped into the bundles. 73 Gunsmoke, Peterborough NH 03458. Send cash, check or negotiable securities.

keep the gate 3 dc bias resistors out of the first-stage compartment.

Undoubtedly, the dual-gate MOSFET is the best of the transistor mixers. With the signal input at gate 1 and the oscillator input at gate 2, the problem of oscillator feedthrough to the rf circuits is greatly reduced. Also oscillator detuning by the rf circuits is minimized. The mixer presents a high impedance to the oscillator circuits, so that the oscillator drive requirement is low. The square-law response of the MOSFET greatly reduces cross-modulation distortion. The MOSFET is also very resistant to overload, which is a highly prized characteristic for mixer operation.

A Motorola MFE 3006 silicon nitride passivated dual-gate MOSFET is used for the mixer. The gate breakdown voltage ratings of ±35V are considerably greater than the ratings of the unpassivated MOSFETs. Because very high steady rf voltages may appear across the mixer terminals, the higher breakdown voltages of this transistor are deemed more appropriate. This transistor is still quite vulnerable to voltage spikes so that handling precautions are necessary. (The Motorola MFE 3007, by the way, is an improved version of the MFE 3006.)

The present *mixer–local oscillator* injection voltage is 2.5 peak (1.8V). Higher injection voltages will produce more gain, while a somewhat lower injection voltage should produce slightly less mixing distortion. Distortion control and gain are both excellent at the present 2V peak oscillator injection level.

The 14–18 MHz mixer output coil has a fairly wide bandwidth so that no readjustment of the converter is required during operation over the entire 144–148 MHz range. For receivers with input impedances other than 50Ω, the turns ratio of the mixer output coil should be adjusted to give a suitable bandwidth.

By the time this article appears in print, some manufacturer will probably be marketing a dual-gate MOSFET which has the low noise figure of the RCA 3N159, the protective diodes of the RCA 40673, and the silicon nitride passivation of the MFE 3006. This could possibly be the ultimate in silicon channel MOSFETs. Of course, a second manufacturer may later one-up the first by marketing a gallium arsenide channel MOSFET, and then later still, a third may bring out an integrated circuit that has... There is nothing like free enterprise to keep the manufacturers sharp and the ham builders happy.

The fifth-overtone oscillator circuit is excellent. It has exceptional amplitude stability, adequate frequency stability, good output power, and low output impedance. It was suggested by Bill Carver K6OLG, who believes it may be a variation on an original design by Frank Jones W6AJF.

The TIS34 J-FET doubler has a fairly high input impedance, a high output voltage, and is very simple to construct. The 65 MHz fundamental is better than 20 dB down from the 130 harmonic in the doubler output. This ratio is not earth-shaking, but it is adequate for the application.

The oscillator–doubler combination produces a strong, stable output, and can operate over a dc range of 5–25V.

The converter is designed to be used with a 50Ω antenna and a receiver of approximately 50Ω input impedance.

Construction

A 5 x 10 in. brass sheet of 40 mils thickness serves as the chassis plate. The shields are made of 30-mil brass plate and are bolted to the chassis plate. The brass plate on my unit (pictured) has been tin-coated for appearance and contact resistance stability. The tinned brass plate is held to an inverted 5 x 10 x 3 in. aluminum chassis by sheet metal screws. Aluminum and tin are more galvanically compatible than aluminum and brass. Of course, any two dissimilar metals in contact can produce corrosion if the conditions are right. The tin–aluminum combination used here should give no problem. Figure 2 is reduced-size template showing hole positioning, shield placement, and relative hole sizes.

Transistor sockets are not used. The leads are soldered directly to button mica bypass capacitors, shield feedthroughs, or to ceramic standoffs. All ground lugs are

soldered directly to the chassis plate.

Ceramic slug-tuned coils are used throughout with two exceptions. Air-core coils, with their higher Q values, are used for the antenna input coil and the doubler output coil. (A complete parts list appears in Table I.)

The ferrite beads are novel and may be replaced by 33Ω resistors, if desired. Ferrite beads have the advantage that they have zero dc resistance – a disadvantage is that their ac resistance is significant only above about 50–100 MHz.

This converter probably should not become a first VHF project. At 2 meters, capacitors can look like inductors and inductors can look like capacitors, regardless of what is stamped on the outside of the component.

The oscillator should be built and tested first. A 2N918 or MPS 918 must be used in this circuit. When the oscillator is performing well, the doubler can be added. A TIS34 or 2N3823 should be used. A TIS88 (2N5245), MPF107 (2N5486), or 2N4416 with their higher gain may cause undesired oscillations.

When the oscillator–doubler chain is working, add the mixer. Use an RCA 40673 protected MOSFET for experimentation at this point since the other MOSFETs are too easily damaged by constant insertion and easily interchanged.

Any problems in the oscillator–doubler–mixer chain should be solved before installing the two rf stages. The second rf stage should be added and made stable. Then the first rf stage can be put in. All dc bias resistors of the first rf stage except the source resistor should be kept out of the first rf stage compartment.

After the converter is completely stable, the top on the antenna input coil should be adjusted for minimum noise figure. This should be done with a noise generator, but a weak 2 meter signal should also suffice.

The builder may find that the capacitor values needed in the tank circuits differ from those given on the schematic. This is to be expected, since slight geometrical changed can affect the frequency response of tuned circuits at 2 meter frequencies.

Unprotected MOSFETs are easily

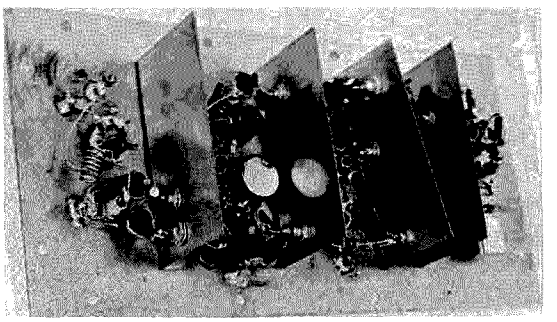
Construction details and component placement are clearly shown in this head-on view of the segmented converter.

damaged by improper handling procedures. Adequate procedures to prevent damage are as follows.



1. The soldering iron tip should be grounded to the converter chassis.
2. The lead to be soldered (or the lead that is connected to the point to be soldered) should be grounded to the chassis with a clip lead.
3. The metal ring supplied with the transistor can be replaced with a ring of solder if the solder firmly contacts all four leads.

Once the MOSFETs are in place and the converter is working properly, there should be no more concern about damaging the MOSFETs.

Performance

The following results were obtained with the antenna coil tuned to 146.0 MHz, the second rf coil tuned to 144.5 MHz, the third rf coil tuned to 147.5 MHz, and the mixer output coil tuned to 16.0 MHz. Other combinations may work better with a different antenna and receiver.

1. The measured noise figure is about 3 dB.
2. The measured gain is about 50 dB.
3. The measured gain control is about 40 dB for a 0.1V rms signal, and about 60 dB for a 10 mV signal.
4. The bandwidth is wide enough that a 3 dB noise figure and a fairly constant gain persist over the entire 144–148 MHz range with no readjustments on the converter.
5. A 0.1V rms antenna signal produced no significant distortion in the converter; however, a strong signal may produce distortion in the receiver mixer, since the converter can put several volts of rf into the receiver mixer. In this case the converter gain control or the receiver rf gain control should be used to attenuate the

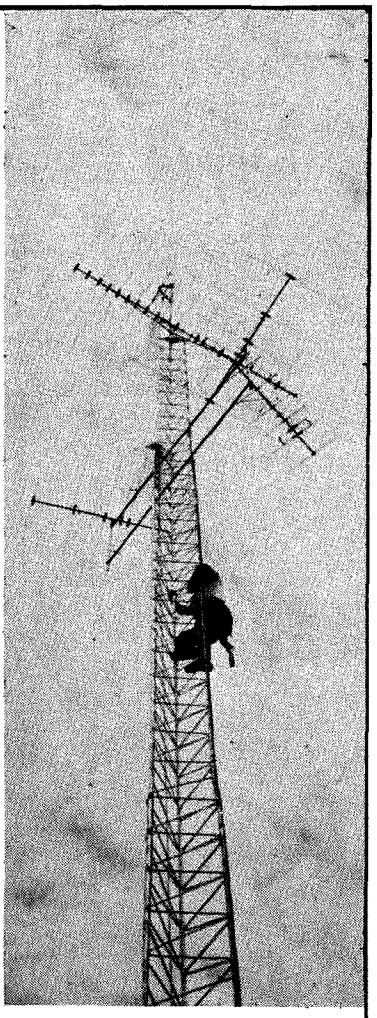
The shielded compartments are (left to right) first rf stage, second rf stage, mixer, doubler, and oscillator. The crystal can be seen against the chassis plate in the oscillator compartment.

strong signal. At no time during initial operation of my unit did the converter gain control require any decrease from the maximum. The receiver gain control did require downward adjustment on very strong signals, however. Incidentally, it was observed during this test that the converter front-end noise was negligible compared to the atmospheric noise. The test location was in the Livermore valley 30 miles east of San Francisco.

6. The converter is completely stable. The local oscillator has never required any adjustment. The two rf stages have never oscillated, but they have remained stable and broadband under all conditions of operation.

Table I. MOSFET 2m Converter Parts List and Symbol Explanations

SM — Dipped silver mica.
BM — Button mica (Erie).
L1 — 7t 18-gage tinned wire, air-wound ½ in. long on 7/32 in. inside dia. Tapped approx 1 5/8 turns from cold end.
L2, L3 — 2¼t 18-gage enam. wire, closewound on ¼ in. dia slug-tuned ceramic form (Miller 4500-4, white core).
L4 — Slug-tuned, 3.1—4.8 μH (Miller 4504).
L5 — 4t 220gage insulated wire wound around L4.
L6 — 6t 18-gage enam. wire, air-wound ½ in. long on 7/32 in. inside dia. Tapped approx. 1½t from cold end.
L7 — 4¼t 24-gage enam. wire, closewound on ¼ in. dia. slug-tuned ceramic form (Miller 4500-2, red core).
RFC1, RFC2 — 2.2 μH molded rf choke (Miller 9320-14).
RFC3 — 1.5 μH molded rf choke (Miller 9310-16).
Z1 — 4.7V zener, 1W (Motorola 1N4732).
D1 — Silicon diode, 100V PIV min, 300 mA min.
F1 — Standard fuse, 1/8A.
XTAL — 65.000 MHz, fifth-overtone, series-resonant crystal.
B1, B2 — Ferrite beaded (Ferroxcube, Stackpole), or 33Ω resistor.
Air capacitors are Hammarlund MAC-10 and MAC-20.
2 BNC receptacles, 2 banana jacks, 15 ceramic standoff insulators.



The experienced VHF builder will find this converter to be a satisfying construction experience. The 2 meter operator will be quite happy with its stable, all-around performance.

2-Channel Search-Lock

Several questions and comments have arisen concerning the 2-channel search-lock article (July 1970).

In Fig. 1, the capacitor connected from the emitter of the unijunction transistor (Q1) should be 0.47 μF. Transistors Q2, Q3, Q8 and Q9 can be 2N3641, 2N706, GE-17, Motorola HEP 50, or any similar type.

The waveforms of Fig. 6 should be labeled as follows:

Top left: emitter of unijunction transistor Q1.
Top right: base 1 of Q1.
Bottom left: collector of either Q2 or Q3.
Bottom right: base of either Q2 or Q3.

The pin numbers listed for IC-1 in Fig. 1 are for the standard 8-pin TO-5 package. If a dual-inline or a flatpack is used, the pin numbers will have to be changed accordingly.

In the picture of Fig. 2, the two lamps mounted adjacent to the upper main power toggle switch are the active channel indicators. I used Dialco subminiature series 252-9951-XXX lamps which are quite small.

I have been asked how this circuit can be modified to provide for more channels. This can be done by replacing the flip-flop (Q2 and Q3) with an appropriate ring counter circuit. I hope to develop such a circuit and present it in an article in the near future. A kit of all the semiconductors required for the 2-channel project is available ($8.88) from Poly-Paks, Box 942, South Lynnfield, Mass. Specify article title, 73, July 1970.

Glen Burnie MD

Computer Comparison

The other month I wrote a series of complex "macros" (I teach computer programming) to serve as a class example. The outgrowth was that I created a little system that could be used to extract data from a data base by a logical combination of keywords. For example, "Extract the record if the keywords *antenna* and *vertical* are present." The next step was to (and what a step) convert the tables of contents of the major ham magazines into punched card form to serve as the data base. My idea was to be able to take all of the technical articles appearing in 73, CQ, and QST for the past 5 or 10 years and get them collected so that surveys could be easily generated. Something interesting happened. . .1 kid you not. . .the ratio of technical articles became most apparent! 73 was way out in front. Then I decided to do the same thing (or try to do it) for articles of interest to FM nuts like myself. Again, but even more dramatically, 73 was out in front.

Autopatches

I can assure you that the "Autopatch" you have described in 73 Magazine is illegal. I know. I just spent three days per month for the last seven months in Washington as a member of the Academy of Sciences panel engaged in a study of the effects of interconnection to the telephone lines. The present tariffs *permit* interconnection of voice or data information through a coupler which acts to isolate foreign voltages, capacitance unbalances, grounds, etc., from the lines.

The tariffs *prohibit* any signaling or control functions from being done by the customer which includes dialing, on hook-off hook controls, and ringing. There are indeed many more considerations than meet the eye in this latter category. Dialing at 10 pulses per second isn't all that is required. The percentage make/break is a more stringent requirement at 61% nominal with 58-64 min/max limits. Maintaining capacitive balance on the lines is essential, otherwise crosstalk will ensue. The possibility of foreign voltages being placed on the lines is another serious concern.

No, I don't work for the telephone company. I am just a member of the electronics industry that was called upon to objectively evaluate the interconnection issue. The panel's recommendation has just been presented to the FCC and I understand the report is available from the Academy of Sciences for $4.50.

Being a ham, I am emotionally torn towards allowing free interconnection but also being a technical consultant, I can see the dangers in allowing free and uninhibited interconnection. Our panel recommendation is to open up the present "telephone company only" approach by allowing *certified* manufacturers and personnel to interconnect. So, there is hope for the future.

Herman Lukoff W3HTF
506 Dreshertown Road
Fort Washington PA

As we interpret the tariff, signaling with foreign equipment through a phone line is indeed illegal, unless a specific phone company authorization is obtained. But dial-type autopatches do not involve phone line transmissions of externally generated tones, even though touchtone patches, of course, do.

Your wrap-up of the make-break-ratio importance is quite correct, but most amateur repeater builders are aware of this. Most use ordinary phone dials for pulsing and adjust the dials as

necessary to comply with requirements. Amateurs are also sensitive to maintaining good isolation between their circuits and those of the phone.

Nonetheless, strictly speaking, the phone companies do require a terminal unit (officially installed) between foreign attachments and the phone, although no ham repeater has ever been known to be reprimanded for illegal interconnection.

The whole tie-in business will eventually be dealt with in specific terms for amateurs, but right now the tariffs appear to be aimed for the manufacturer of interconnect devices and the mass-scale user.

... Ken

Free Speech

It is such articles as K2AGZ's "Free Speech for Hams" which is assisting our enemies to multilate and destroy our American heritage of freedom.

His attack on Vice President Agnew is a good example.

Recently Pope Paul VI said "Too many papers use the press to defame instead of to inform."

This is exactly what K2AGZ has done in his article. Either he has never read or listened to the Vice President's speeches, or he has made up this defamation of VP Spiro Agnew from enemy infiltrations in the press.

President Jefferson once said that if our country was ever destroyed, it will be by infiltration by enemies who will use our freedoms to destroy us.

The checks and balances and criticisms which Vice President Spiro Agnew speaks of, are simply and purely self-defense of democracy and freedom.

Myron R. Fox
45 McKinley St.
Brookville OH

Pleased and surprised by K2AGZ's views in "Free Speech." Hope for more of the same!

Ken Cole
Box 3
Vashon VA

I have subscribed to 73 for a number of years and think the magazine is great for the radio information it contains. However, there are many times recently that I think its EDITORIALS *stink*. It appears to me that you – the editor – can't make up *your mind*: You express a belief that *violators* of the *regulations should* be punished, but not if their breaking the rules helps them maintain their *freedom*.

You say you are for law and order. Perhaps you are, but you sure show a leaning towards those who want to "burn it down" because it is *their right under* the First Amendment.

I still believe that 73 is a good amateur publication. But its editorials *stink!* Maybe a new editor *would improve them.*

W T McAninch
2137 Grayson Place
Falls Church VA

I would like to say that if 73 Magazine is pressing for free speech on the air – the use of obscene, indecent, and profane language – and

that whether it is that type of language to be determined by the one using it – 73 should start closing its doors!

Wayne E. Herron WQMI
1301 Church St
Scott City KS

You must be a new reader to 73 and thus not understand that 73 has no opinions, that opinions expressed in the magazine are signed and are the opinions of the writers only. Some we agree with, many we don't, but it is dishonest to censor out ideas because we don't happen to agree with them.

We reported that the FCC chairmen are having trouble with words and the interpretation of what is obscene, etc., in light of supreme court decisions. On a strictly pragmatic level one might ask what harm a four-letter word is going to do on the air . . . we are seeing it regularly now in books and magazines, and hearing it in the movies. Many people are beginning to believe that there is a possibility that some of our population is becoming adult enough not to be stricken by mere words. It takes more maturity than is generally available to be able to dismiss "dirty" words. Of course, once the emotional impact is gone, they will fade from such prominent use. (We may not notice it, since they won't bother us any more!)

. . . Wayne

FM

Just wanted to tell you that I have been enjoying your recent FM articles and the thicker magazine. I hope you run a reprint of "Chronicles of an Amateur FM Channel." I sure would like to have a copy of that in my library.

Skip Hansen WB6YMH
3614 Homeway Dr.
Los Angeles CA

"Chronicles" appears in the FM Anthologies, Vols. I and II, in its entirety.

. . . Ken

Appreciated the report on the Orlando Hamfest and FM Convention. Also, the mobile phone and search-lock FM articles were FB. Keep up the good work for at least three years (the length of the enclosed renewal).

Charles Durst WA4WTX

On May 26th I sent you a check for $15.00 for a three year subscription to 73 and the "FM Anthology." So far I have received the magazines but not the book. Being new to 2 meter repeater operation I need all the information I can get.

Thanks very much for all the FM articles being printed in 73 and for the special issue. I've been almost completely inactive for years and 73 has done more than anything else to revive my interest and get me back on the air.

Ray F. Caldwell W4VFC
525 Hall's Lane
Madison TN

Sorry about the FM Anthology hang-up. We're having printer problems, and the orders exceeded the initially printed quantity. Another week or two at the latest.

sion. The hobby license would be beneficial for cleaning up the overcrowded conditions and irresponsible operating practices found on 27 MHz. It would also serve to increase amateur activity on VHF. This class of amateur license could be beneficial for amateur radio, providing these newcomers *were responsible* to the spectrum they would be using. This responsibility develops into a need for the knowledge of basic radio theory because this knowledge provides for the appreciation of radio. The theory these radio users need to know is the propagation characteristics of the band they would be occupying plus the general principles of what frequency modulation is (since this is the type of modulation they would be using). They should also know why FM is advantageous over other ways of supplying information to a signal carrier. The basic radio theory I have mentioned here as well as the rules and regulations already proposed, is essential to upholding the quality of amateur radio.

Paul Leary, Jr. WA4WUN
3302 Natchez Lane
Louisville KY

How about a minimum-code requirement, too; say 5 wpm?

You have just sprouted an excellent idea to eliminate the citizen band dilemma, now how about putting your genius to work on this one.

Stanely W. Pugh O. D.
2521 North Proctor
Tacoma WA

I tend to favor the "Hobby" license as described in 73, with reservations on: (1) getting a foot in the door, and (2) code should be retained for all classes except "Hobby." The code is the only prestige we hams have and we *must* retain it.

Mal WA2CDE
Box 321
Hyde Park NY

Yep, I'm all in favor of "Hobby" on 220. We hardly use the band, even in the major population areas–but think of what would happen when and if you could buy a five-channel solid state 1 watter for $69.95!!!! If they can be made and sold for this price for 11 meters, it is not that big a step to 220 MHz, as far as design and manufacture is concerned. Smart people, these Japanese! We are just around the corner from the $100 VHF FM rig, and after that is the $50 walkie-talkie!

Fritz Hervey WB4MSJ
Box 336
Indian Trail NC

. . . So now we call everyone a ham. Why not call CB'ers hams . . . what's the difference? Take 220, but give us more room on 14 or 21 MHz. Don't take only! And keep commercial interests away from ham radio – that's how we lost 27 MHz.

W8AWN

We lost 27 MHz the same way we stand liable to lose any sparsely populated spectrum. Some bright fellow said, ". . . Well, we can place the band for this requirement down on 27 MHz. This frequency is allocated to amateurs, but it's not used much."

. . . Ken

Crooked QSLing

VK4SS's article on QSLing really put it in black & white (73, July 1970). I get so disgusted with DXing that I hardly ever do it, preferring a nice domestic contact to working any DX. Reasons:

1. Pileups. I am too impatient waiting for a 20-second contact, fighting it with people who in all probability are using somewhat in excess of legal power.

2. Discourtesy. With all the break-break-break business it sounds like a bunch of CB'ers. One man in Fiji who used to live here can hardly hear his scheduled contact with the QRM aimed his way.

3. QSLing. The article says quite a bit. Personally, I like receiving and sending cards, and would gladly do it on every contact. Anybody who sends or asks for a card gets it from me.

So many of these people say, *"QSL 100%* by bureau" or some such trivia; or "Will QSL direct for IRC." So what happens? Maybe 50% come through. I went through a bunch of logbooks and made a list of stations who have not QSLed after a reasonable time (3–4 months). Maybe if a bunch of us made lists some of us could refer to the list before wasting a stamp.

One of my friends in Modesto is making up a "lid" list with a similar intention. He is going to award a "lid of the year" award with call letters engraved in a used toilet seat to the worst operator in the area. Already two or three are in mind – these guys who bumble in on a QSO with a linear, hollering "Can you read me?" while the guy they want to contact is transmitting.

Paul Schuett WA6CPP
14472 Davis Road
Lodi CA

Just finished reading VK4SS's written word about QSL "con games," and must express my approval. I'm probably not the best myself in the category of QSL WN QSLed – I just don't QSL unless requested and I don't work that much DX any more. I have been DX in the past and I can remember what it cost me after one weekend in '65 for a United Kingdom Scout Jamboree on the air and I looked over the log: 126 sent, 4 rcvd from KJ6!!

'Nuff said!

K2DAK/WA6DEK

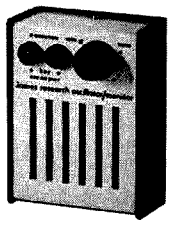
Wha' Happen?

I received my July 1970 issue of 73 incomplete; pages 33 through 48 are missing. I enjoy your magazine very much (even with 16 pages missing).

Please don't fall into the rut the other magazines have and print a bunch of meaningless junk about contests and the like.

I would appreciate another July issue or at least those 16 mysterious pages.

W T Glenn
Rt. 1
Levelland TX



The 16 pages contained meaningless junk about contests and the like.

. . . Ken

Nets, Nets, Nets, Nuts!

One big problem on the various bands, is this "net" business.

mark 2
oscillator/monitor

- makes an audible tone to monitor the RF of any CW transmitter from 10Mw to 1 Kw & 100Kc to 1000Mc, using only an 8" pickup antenna.
- can be self-triggered for code practice or the testing of solid state components and circuits.
- aids in tuning up & testing RF oscillator and power circuits.
- 4 transistor, 2 diode circuit, speaker, tone adjust, AA pencell, test tips, 8" ant., & magnetic base.
- cabinet is 16 gauge black & clear anodised aluminum, 3.4 x 2.3 x 1.2"

It seems that there ought to be some brain-busting on this, by those who claim to have brains. Some of us have been successfully driven off some bands, by the preponderance of nets.

As a kind of last resort, I am down on 21 MHz now and most of my friends are there also. However, the Peruvian Disaster Net, on 21.423, asked for and got 5 kHz on either side of that frequency. Two other nets asked for the same, also working Peru stations. All this was in the General segment of the 21 MHz phone band.

Someone suggested that all work be shifted to the section from 21.200 to 21,350, but it was vetoed. I took a look down there and found about six stations working.

Nearly everyone honored the request by the Peruvian net, as handled by W2AIM, who did a great job hour after hour.

I do not think any authority would hinder such emergency work if it was done in the blank sections of the various bands. And believe me, there are some terribly blank sections.

Now please don't give me that incentive jazz; I am far to old and feeble to compete with the young smart guys running around loose these days. So let's hear from some of the brain power up there in New Hampshire, about this NET business, and how best to handle it from now on.

Martin M. Hellman K2TAJ
61 Scott Ave.
Staten Island NY

The other evening I ventured up into the General part of 20 meters and, as usual, tuned for a blank spot (well, relatively blank) and asked if anyone was using the frequency. Yes, indeed, please QSY off the Missionary net, OM. Okay, glad to oblige, but when does the net close? In a half-hour, but then the Doctor's net will be using the frequency. I tried another channel . . . no, please QSY, this is the Maritime Mobile net. Another . . . please QSY, this is the YL net. Another . . . please QSY, this is the International Sideband net. This is the County Hunter's net. This is the Intercontinental Phone net. This is MARS, you're out of band. . .

Obviously, quite a problem has developed now that all of the nets that were scattered through the phone band a couple years ago are now jammed into the 75 kHz left for the Generals. I think this tells us why more and more phone patches are blooming in the hitherto DX part of the band around 14.200—.250.

During the prime evening hours there seems to be some sort of organized net just about every 10 kHz (it only takes seven nets to fill the band). Now, while I think that the whole idea of nets is excellent, I can see that somehow something has to give. Nets, with 10—50 stations all on one frequency, are obviously a very efficient way of providing activity for a maximum number of stations in any given band. And the pursuit of a special interest by a group obviously makes amateur radio more fun for those involved, another plus. Some of the nets provide fine public service (such as the Eyebank net) and emergency help (WCARS, etc.) But it is getting like the old prewar 80M band where there is room for nothing but nets (Postoffice net, Airport net, Broadcast Engineer's net, etc.) and there would seem to be a rapidly growing need for someone to provide a net registry service

which would stagger the nets by time and channel for the maximum use of the few General frequencies still left.

. . . Wayne

International Crystal PC Modules

The little PC boards made by International are more fun than anything but girls: they go together fast, work right the first time, and they are cheap. I think they are one answer to the problem of getting kids to tinker. Some of them may be overwhelmed by the complexity of today's gear and are scared off. These little boards are the easy way to learn fundamentals and we need an article about them.

F. C. Hervey
Rt. 1 Box 336
Indian Trail NC

Not Guilty!

I have delayed sending in my renewal so that I might add a comment as to my opinion of the makeup of your little book. Personally, I find it tops in its line – in particular, the brief but complete and detailed articles on the projects that a person can still find time to knock together. I had been a captive to the "Hartford Clique" for 15 years and finally woke up. As a consequence, I did not subscribe to any ham magazines until I saw a counter copy with an interesting article 73. So after a period of 10 years as a nonbeliever I am reading again. I have 35 years in advanced electronics with broadcasting, commercial, and industrial and the last few years in space electronics. Therefore, I resent my hobby being turned into something that only high-level electronic plants can produce. The big plants manufacturing ham equipment must love Hartford for the part they played in pushing SSB. (Yes, I am an appliance operator on the lower bands.) Let's *build* on two meters and up and try to keep it a hobby.

John B. Kihm
17203 Haas Ave.
Torrance CA

If your reference to "Hartford" implies that the League is responsible for encouraging sideband initially, I think your wrath is misdirected. The ARRL was one of the last to advocate SSB.

. . . Ken

Something for Everyone

I have had an amateur ticket for almost 9 years now, and I have seen all kinds of Amateur Radio magazines.

Most are fair in some areas, but not all areas. 73, in my opinion is great in all areas. Best amateur magazine on the market at any price.

Every amateur can find something of interest in 73 and that is what the amateur radio magazine business is all about, something for ALL amateurs.

I operate 40, 20, and 15 meter CW exclusively. You may say CW is oldfashioned, but if you become proficient at it, it is just as enjoyable as AM, SSB, FM, or any other mode. That is what I like about amateur radio; everyone has an opinion as to what he enjoys. As for the code test of 20 wpm for the extra, it ain't all that hard to learn if you apply yourself.

PEP's *SPECIAL!*

CIRCUIT BOARD COLLOSSAL

Loaded with components up to $100.00 value. Bought out one supply house– FIRST come–FIRST served!

All Different! All Complete! First Line Units!

If you don't feel that you got your money's worth–full return guaranteed.

3 DIFFERENT GROUPINGS TO CHOOSE FROM

GROUP A – **Actual Value $15.00 – PEP Price $1.25**

SAMPLE A–1: 200 diode – 7 transistors – over 50 resistors – complete with board.

SAMPLE A–2: Four I. C. Mounting Blocks – 3transistors – over 25 resistors – complete with board.

GROUP B – **Actual Value $20.00 – PEP Price $1.75**

SAMPLE B-1: 8 I. C. Mounting blocks – over 50 resistors – 32 transistors – over 30 diodes – complete with board.

SAMPLE B-2: 32 transistors – over 100 resistors – capacitors – over 15 diodes – complete with board.

GROUP C – **Actual Value $50.00 – PEP Price $4.50**

SAMPLE C-1: 22 in-line I.C.s – over 75 diodes – 20 trans. – over 50 resistors – capacitors – complete with board.

SAMPLE C-2: 22 in-line I.C.s over 50 diodes – over 50 resist – capacitors – complete with board.

DX'er's Complaint

Greetings from Monte Limbara, Sardenia, 4500 ft above sea level on the northwest coast of the island, overlooking the beautiful Mediterranean, home of IS1DFO.

Just finished reading about JY1 and agree completely about just how discourteous some hams are in this world. I can understand just how King Hussein feels trying to have a QSO with someone about various subject without some clown getting in there and hollering. . "Break-A, break-A, break-A," and for the most part never identifying properly, going over it several times – not only to irritate you but to let you know without a doubt that they are on your frequency with their harmonic-rich distorted modulation and to impress you with the fact that they aren't gonna shut their mouths or turn off that international homebrew jammer until you acknowledge them. I enjoy being able to talk to guys and gals all over the world and really feel privileged to share part of the limelight in being able to pass on signal reports good and bad to those desiring contact with this island . . . but there should prevail certain tact on radio, and the few who do ignore the basic rules of being polite and waiting just cause hard feelings. We make the most of it and am sure that the many we have worked enjoyed working us because we make it a point to say a few words to make it more meaningful than just a normal signal reports.

Joe (John) Johnston W5AOE
Jacksonville AR

(W2NSD cont. from page 10)

the past reporting I had read on the subject from our newspapers.

After returning home I paid a lot more attention to the Mideast, reading every news item or article that I could find, plus watching all special television reports. One of the most fascinating television programs on the subject was on NET, called "The Advocates." They argued the Arab side of the problem one week and the Israel side the next. They mentioned that the Quakers had produced a booklet on the subject called "Search for Peace in the Middle East." I sent for one.

The Quaker book is exhaustively nonpartisan and, for a small book, does a beautiful job of putting everything into perspective. They cover the Arab arguments and problems as well as the Israeli.

If you are at all interested in an objective history of the situation, complete with an espousal of both sides' problems and complaints, you should read this booklet. It certainly is an eye-opener. To make this easy for you I have arranged for our book department to have some of these on hand. Send $1 (75¢ plus handling charges, etc.) for the Quaker book to Radio Bookshop, Peterborough, N.H. 03458. Why not know the whole story? . . . W2NSD/1 ■

(Leaky Lines cont. from page 14)

any mailings they might care to send me. They have informed me that they are placing me on their mailing list, and will take the matter under advisement.

I am hoping that these inquiries will bear fruit, and will keep you abreast of the matter via Leaky Lines. Lest anyone get the idea tha nothing will come of it, I might remind him that in at least two similar instances, offending signals were dealt with through the determined efforts of amateur operators. One, a high powered teleprinter operated by NSS at Annapolis, was cleared up through the talents of W4UMC, principally. The other, a terribly troublesome Teletype in Bogota, Colombia, some years ago, was halted through the use of the telephone. A very cordial call to the office of the head of the Colombian mission to the UN resulted in the prompt cessation of the interference. Sometimes simple solutions are the best. In any case, all we can do is to try.

* * *

Now that the amateurs of practically every country in North and South America have pitched in unstintingly to render assistance to beleaguered Peru in its hour of travail, it will be interesting to observe the future attitude of that nation toward the United States. U.S. hams have been most dedicated; some of them have even stayed away from their jobs and have lost sleep, continuing to man their stations, so that the lines of communication could be kept open. I'll not go into details concerning the actual operation, since there are certain to be many articles on that subject. Let us simply state that if it had not been for all these dedicated hams, plus the presence of the U.S.S. Guam, practically converted into a hospital ship, many lives would have been lost that were saved.

In the recent past, of course, the property of some of our compatriots had been seized by Peru. Fishing vessels were interned . . . oil company installations had been expropriated. It seemed that our stock in Peru had fallen mighty low. It is a source of great pride to me, and I am sure to all Americans, that such cavalier treatment at the hands of this small country did not deter us from our willingness to offer all our resources in order to ameliorate the terrible tragedy which struck without warning.

73 Reader Service Coupon

Now we don't say that every single reader must buy every last product advertised in 73. We believe that, but we don't say it. The very least every reader can do is to put on a show of interest in the products herein advertised. To make this a simple task, even for the laziest reader (now there is a contest for you!), we have cleverly arranged the advertising index to double as a readers service coupon. All you have to do is tear it out (or photocopy it) and send it in with the appropriate boxes marked. (We have a prize for the most boxes marked . . . a silent prayer of thanks from the publisher). We'll accept postcards, slips of paper, or almost anything else that lists the companies you want to hear from and your address.

No one likes to go into a store without buying something, right? It is the same with these information requests. You will be expected to buy something. Oh, it doesn't have to be a $50,000 antenna system, but it should be something modest . . . a transceiver . . . a linear . . . you know. We'll leave the decision up to you, knowing that we can trust you to do the right thing.

And we are definitely not saying that the use of this service coupon has any curative powers, but we cannot but notice that many readers report remarkable relief from simple backache, headaches, lumbago, and acid indigestion after sending in their coupon. Why take any chances?

73 Magazine is published monthly by 73, Inc., Pine St., Peterborough, New Hampshire 03458. Subscription rate: $12.00 for three years, $6.00 for one year. Second Class Postage paid at Peterborough, New Hampshire, and at additional mailing offices. Printed at Menasha, Wisconsin 54952, U.S.A. *Entire contents copyright 1970 by 73, Inc., Peterborough, New Hampshire 03458.* *Phone: (603) 924-3873.*

We do not claim that subscribing to 73 will make you wealthy, yet we cannot overlook the many reports we have received from our subscribers telling us that soon after subscribing to 73 they found buried treasure, fell heir to a fortune, or discovered a pearl in their oyster. It is difficult to overlook the strange coincidence that the magnitude of their windfall seems to always be in direct proportion to the length of the subscription taken to 73. Is a subscription to 73 really a money magnet? Can you afford not to make sure about this?

HAM DOCTORS QSO WITH EARTHQUAKE AREAS IN PERU

Communicating with doctors in the earthquake disaster areas in South America to provide medical aid and with its international ham doctor members were some of the additional activities carried on by the Medical Amateur Radio Council (MARCO) members attending the recent American Medical Association Convention in Chicago. Over 10,000 doctors were in attendance.

MARCO members talked via Hallicrafters amateur radio equipment to fellow doctors in the earthquake disaster area near Lima, Peru and also handled vital medical messages between doctors from all parts of the world attending the AMA convention and their home offices.

The Hallicrafters Company, Rolling Meadows, Illinois, a subsidiary of Northrop Corporation donated the use of the radio equipment to MARCO for its convention. It was the only radio equipment used by the members.

The major purpose of MARCO is to establish personal communications among its members and their ham colleagues for dissemination of factual medical, electronics, and communication information, both theoretical and practical. It was formed in 1966 as a charitable and scientific membership corporation designed to meet the medical–electronics and radio communication needs of its members. It now has over 400 members.

MARCO, headquartered in Manchester, Conn., has identified itself with doctors in the United States, Canada, and other countries in the world where there are doctor hams. The doctor members get to know their colleagues and develop professional, avocational, and social associations.

While attending the recent American Medical Association convention in Chicago, ham doctors communicated with fellow doctors in the earthquake disaster area near Lima, Peru. Each member of the Medical Amateur Radio Council (MARCO) used amateur radio equipment donated for the vital occasion by Hallicrafters. Standing and listening to the voices of doctors from Lima and other parts of the world was Bud Drobish (W9QVA), Assistant Sales Manager of Hallicrafters. MARCO held its fourth annual meeting and conference during the AMA convention. From left to right: Dr. Earle E. Weston (W8BXO), Birmingham, Mich.; Bud Drobish; Dr. Maurice N. Richter (K7UWP), Phoenix,

FCC PETITIONS IN PROCESS

The following is a comprehensive tabulation of amateur petitions now awaiting action by the FCC. Thanks to Bob Chapman (W1QV), ARRL New England Division director.

RM #	DATE FILED	SUBSTANCE
968	3/66	Use of other than 220 MHz to remotely control RACES stations.

1116	3/67	RACES rules, control of nonamateur licensees.
1306	5/68	Expand 10, 15, and 20 meter phone.
1346	8/68	Senior Citizens license.
1349	9/68	Expand phone privileges for KP4 licensees.
1363	10/68	"Advanced" Technician License.
1392	12/68	Permit RTTY speeds of 60, 75, and 100 words per minute.
1429	3/69	Permit F-4 at 144 MHz.
1454	5/69	Allow Techs to use CW, 80 through 10 meters.
1455	5/69	Counterpart call signs.
1456	5/69	Permit Techs to have same CW privileges as Novices.
1477	9/68	Expand phone bands for DX QSOs only.
1478	4/69	Permit 40F2 emission by RACES stations on 144 and 220 MHz.
1479	5/69	Expand Extra phone bands.
1512	9/69	800W output above 420 MHz.
1516	10/69	Tech privileges, 21 MHz Novice band.
1520	9/69	CW and phone segments, 6 meter Advanced band.
1521	10/69	Technician CW privileges.
1526	10/69	Technician CW privileges, 10 meters.
1535	11/69	Technician privileges, 29.5—29.7 and 144—148 MHz; dual holding, Novice and Technician.
1536	11/69	Counterpart call signs.
1538	11/69	Higher RTTY speeds of 60, 67, and 100 wpm.
1542	12/69	New repeater rules.
1544	11/69	Extra class phone, 40 and 20 meters, or expand 20 phone for Extra.
1550	1/70	Expand phone bands, 80—15, half for Extra, half for Advanced.
1568	2/70	Novice privileges for Technicians.
1590	3/70	"Grandfather" old Extra Firsts.
1591	3/70	One-year wait for Extra.
1593	3/70	Amend incentive licensing frequency allocations.
1597	4/70	1 x 3 call signs for new Extras.
1602	4/70	Novice privileges for Technicians.
1603	4/70	Expand phone for Extra and Advanced.
1604	4/70	Change ID rules for short QSOs.
1614	3/70	Expand phone bands for Advanced and Extra; widen General Class phone; permit Techs on 28 MHz.
1615	3/70	Conditional Class limited to one year; no new Technician; create Intermediate and Communicator licenses.
1616	4/70	Expand phone, abolish reserved bands.
1629	5/70	Create a military examining point in Germany for FCC amateur exams.
1631	5/70	Specifically provide for discussion of political matters and other controversial subjects in the amateur bands.
1633	5/70	Create a "hobby" license 220.5—224.5 MHz, 5 kHz FM, FM, 100W, mail exam on rules only, NA1—NZØ call call signs.
1644	6/70	Expand phone bands for Advanced and Extra; widen the General portions of the present phone bands; reduce Novice band on 15 to 21.1—21.2, but add a new one 28.1—28.2; permit Extra class to use 7075—7100 kHz for SSB and add a note to the rules restricting 7100—7300 Hz work to Region 2 only.

For copies and additional information on these petitions, write to: (refer to RM numbers)

Sitting is Dr. J. Stanley Carp (K1EEG), Saugus, Mass. and directly behind him is Joseph G. Boris, Executive Secretary of MARCO.

QSL Manager of the Month

George Studd (ZL2AFZ) has been named QSL Manager of the Month by Scotty (WA5UHR), who makes such awards periodically on behalf of his QSL service.

According to Scotty, George is a great DX'er and a credit to our hobby. Along with several DXpeditions, he has traveled 45,000 miles, covered 33 states, 6 Canadian provinces, and visited the north Arctic circle and Alaska. When he was in the States he took over 1200 color slides, spoke on 2 TV shows, 2 BC stations, dozens of radio clubs, Kiwanas, schools, churches, etc. George has received a number of DX awards. He is QSL manager for VRIQ, ZL2AFZ/C, ZN1BN/A, ZM3PO/C, AXØLD, ZM1AAT/K, ZL2ANX. He was previously manager for ZL1DS/C, ZL1TU/C, and ZL1IL/c.

Nominations for QSL Manager of the Month should be sent to Scott's QSL Service, 1510 Lynnview, Houston, Texas 77055. Include name and call of manager to be nominated and a short summary of why he deserves to be nominated.

Alabama Hamfest Success

Eight hundred hams and their families braved the summer sun of Northern Alabama to attend the Huntsville hamfest on August 16th. The event, held in the air-conditioned splendor of the Huntsville Mall, was a complete success by any standards.

The hamfest started Saturday night with a talk by Wayne Green giving some perspective to the present situation of amateur radio in terms of its history, the ITU, and the FCC. Slides were shown of his recent trip to Jordan and his visit with King Hussein as well as a previous trip to Nepal. All questions were answered, pertinent and impertinent.

On Sunday there were RTTY displays, FM get-togethers, DX displays, a couple of acres of swap-fest, Bingo for the XYLs, and frequent showings of the Dave Bell film on amateur radio.

FCC REGULATIONS PROHIBIT CONTESTS!

ARRL in Chaos

FCC Amateur Radio Rules and Regulations Part 97.125 says, "No licensed radio operator shall willfully or maliciously interfere with or cause interference to any radio communication or signal."

Could that rule be clearer? No willful interference with any radio signal. That means exactly what it says. If you have even the slightest reason to believe that your signal might cause interference to another signal it is against the rules for you to transmit.

Contests, those giant exercises in willful interference, are obviously absolutely illegal.

The preponderance of contest activity in the U.S. is sponsored and promoted by the ARRL. Since we must assume that the directors and officers of the League are familiar with the amateur regulations, then the only conclusion possible is that they are knowingly promoting and encouraging an illegal activity which causes tens of thousands of amateurs to break the FCC regulations.

DX Pileups Illegal

If it is illegal to cause interference to one station, just think how illegal it must be to cause willful interference to dozens or even hundreds of stations. Think about that the next time you are about to add your potent signal to a pileup calling a rare station. Is working that station really worth the torment you will suffer knowing that you have committed multiple violations of the regulations, not to mention the suffering and anguish you have caused the poor chaps on the channel whom you clobbered. One would have to be a pretty lawless and callous individual to chase DX in view of all that.

WIAW Breaks Regulations

Yes, even sacrosanct WIAW is in continuous violation of 97.125. Just tune in anytime to the broadcasts of League affairs and you will notice that WIAW comes on frequency on schedule and causes willful interference until everyone moves off channel for them.

Is This Serious?

The law is the law and many bleeding hearts feel that all laws should be observed, no matter how inappropriate they may be. When a law is bad the question arises, should we ignore the law or try and change it?

The idea behind 97.125 is fine and the law will cause little trouble if everyone continues to ignore that it exists. Unfortunately, the lid has been opened recently by the FCC. Two amateurs, both calling a third station simultaneously, with the goal of seeing which had the strongest signal, received an FCC citation citing 97.125.

The cure is simple. If one of you will write a letter to the FCC, with the usual 14 copies, asking that the words "willful or" be removed from 97.125, then we would have the same law, but without the bad part.

New DX Certificates Available from 73

WORKED NORTH AMERICA

Card confirming two-way contact with amateurs in each of the following areas must be furnished: W1 through WØ, KL7, VE1-8, including separate cards for PIE, CBI, NS and NB in VE1, FP8, VP7, and both Yukon and NWT in VE8, a total of 27 cards. Cards should all be dated 1970 or later.

WORKED CENTRAL AMERICA

Cards confirming two-way radio contact with amateurs in each of the following areas must be furnished XE1-2-3, XF4, VP1, TG, YS, HR, YN, TI, HP, KZ5 (a total of 12 cards). Cards should be dated 1970 or later. It

DX NEWS ROUNDUP-NEWS FROM ALRANIA

From the West Coast DX Bulletin comes this late report filling in details on the OH/ZA effort. The OH group drove by car some 700 miles to Copenhagen and flew directly from there to Tirana. No answers had been received to their letters of inquiry for information and they went on the trip to see what might be accomplished. At customs they were passed through without any examination and they carried their rig to their hotel. They then learned that they would not be permitted to go on to Tirana. With the help of their Albanian guides they set up their antenna and started working the pileups. This lasted for about nine

During the balance of the stay the OH group tried to get a special visa to visit Tirana and discuss the situation. Direct efforts did no good, but finally the Albanian guides were persuaded to make arrangements which would permit them to visit the Albanian capitol. They went there on the last day of their stay and had a one hour meeting with the vice director of the Ministry of Communications. They learned that their letters had been received, but had not been answered because there was no provision for amateur radio in Albanian law, it being neither allowed nor prohibited. He asked that more information be sent before any future

Rogues Gallery. *This photo of C. R. Lander (ZL3ACY) won first prize in a recent competition sponsored by the North Canterbury Amateur Radio Club, Canterbury, New Zealand. As winner, Lander received a subscription to 73 Magazine and his photo appeared in several international publications.*

is the areas that are important, so special call prefixes are acceptable.

WORKED THE CARIBBEAN

Cards confirming two-way amateur radio contact with each of the following areas must be furnished: KS4 Swan Island, KS4 Serrana Bank, KS4 St. John, VP2M, VP2S, VP2V, VP5, FG7, FM7, FS7, PJ St. Martin, PJ St. Eustatius, PJ Aruba, PJ Curacao, PJ Bonnaire, PJ Saba, 8P6, 6Y4 Trinidad, 6Y4 Tobago, YVØ, HKØ San Andres, HKØ Baja Nuevo. Cards should be dated 1970 or later. Certificates are available for 20, 30, and 40 areas worked.

WORKED SOUTH AMERICA

Cards confirming two-way amateur radio contact with each of the following areas must be furnished: HK, YV, PZ, SR, FM7, PY, LU, AP, CE, HC, OA, CP and CX, a total of 13 countries. All cards must be dated 1970 or later.

WORKED EUROPE

Cards must be furnished confirming two-way amateur radio contact with each of the following areas: G, GM, GW, GI, GC Jersey, GC Guernsey, GD, EI, F, D, DL7, DM, EA, EA6, FC, C31, HB, HE, OE, OK, HA, YU, OZ, LA, SM, OH, OHØ, OJ, CT, YO, AZ, SV, SP, I, M1, HV, IS, IT, SVØ Crete, SVØ Dodecanese, LZ, TF, OY, ON, PA, LX, ZB2, 4U (Geneva), 9H1, TA (European), SMOM, JX, JW Svalbard, JW Bear, UA2, UA, UB5-UT5, UC2, UD6, UF6, UG6, UO5, UP2, UQ2, UR2, a total of 65 areas. Certificates are available for 50, 60, and 65 areas.

Contacts may be made on any amateur bands using any mode. All cards must be dated not earlier than 1970. Send cards with note describing certificate applied for and listing the areas confirmed along with one dollar to cover the cost of handling. Send to 73 Magazine, Peterborough, N.H. 03458. Foreign amateurs may apply through their national societies and send along an affidavit attesting to the inspection of the cards and seven IRCs.

hours.

The next morning the Albanian authorities were at the door, apologizing for not having noted the declaration of the radio gear on their entry. They advised that the bringing of radio into the country was prohibited and the equipment would have to be held until they left the country. The operation was over by 0700Z on July 11th.

The Albanians had apparently set up a monitoring station about 200 yards from the hotel before the visit. The transmissions were recorded and checked by English-speaking Albanians. The OH group kept all transmissions in English, commenting favorably on the Albanians and their treatment at frequent intervals. Whenever they left the hotel they were followed. Why was the rig impounded? Perhaps the authorities wanted to examine it or possibly they were not anxious to sit and monitor the pileups for a full week. It was returned in good condition. In retrospect the OH group felt that the decisive factor in the future Albanian attitude would be what benefit the country might derive from amateur activity.

Looking ahead, the OH group are making plans for another effort in June 1971. Documentation has been forwarded to ARRL and DXCC credit is expected. Some 600 W/K's were worked. The OH group is grateful to the International DX Association for making a modified HW-32 available for the trip.

Canada–Sweden Reciprocity

Ottawa. Canada's director of Telecommunications, Mr. W. J. Wilson, has announced that his country is now recognizing reciprocity with respect to "temporary amateur operating privileges with Sweden." For Swedish permits issued for a period of less than 30 days, Wilson stated, the fee is 40 Swedish kroner. Wilson also supplied the following excerpt from the Code of Statutes of the Swedish Telecommunications Administration:

Any foreign radio amateur applying for a temporary permit . . . shall submit his application via the authorities issuing permits in his native country, which authorities will forward it to the Central Administration of Swedish Telecommunications together with their comments. The application, which may be written in Swedish, Danish, Norwegian, English, French, or German, should be submitted early enough to reach the Central Administration not later than two months before the permit is required. It shall be accompanied by a certificate of good conduct issued by the police authorities of the applicant's native country.

QSL Delays

A note from Garth (5H3LV/A) explains that QSLs for the Zanzibar expeditions have been delayed a bit due to their being sent to U.S. QSL bureaus during a Canadian postal strike.

A cable from King Hussein tells us that all QSLs for JY1 have been forwarded through the bureaus.

While most of the individual bureaus work quickly and efficiently, the biggest holdup seems to be at ARRL headquarters, which reportedly holds cards up to six months or so before sending them along to the individual bureaus.

Haiti Active for DX Contest

by W6GC

W6WLH, W6EJJ, and W6GC will be operating HH9DL during the CQ worldwide DX contest on October 24 and 25. They will operate 5 bands, 10 through 80 meters, for the entire 48 hours of the contest. There are no particular frequencies chosen as yet, but some operation will be outside the American phone bands using split frequency. For a part of the time the listening frequency will be in the General portion of the bands so everyone will have a chance.

This is reportedly the first time any Haitian station has operated the contest. The group plans to arrive in Haiti about October 20 and will be on the air both SSB and CW for about 3 days before the contest.

Canada–U.S. CB Reciprocity

Under an agreement between the United States and Canada, effective July 24, 1970, visiting Canadians who hold valid Canadian licenses in the general radio service may request permission to operate their radio stations in the United States.

Permission to operate their radio stations in the United States may be requested by completing an FCC Form 410 until November 1, 1970, at which time a new form 410-B will be available for this purpose. All applicants for such permission must have read and understood Part 95 of the Commission's Rules and all operation must be in compliance with these Rules. Canadians while operating in the United States under such authority must identify their stations by their Canadian call sign followed by the station's geographical location (city and state).

73's New Award Lineup

A whole new spectrum of certificates are being awarded by 73 for amateurs who manage to fulfill the stated requirements – which won't be easy.

Worked the ARRL Certificate

This award is available to any licensed amateur who can provide proof of contact with any four of the current sixteen ARRL directors, all within one year of the date of application. Stickers are available for proof of contact (within one year) of eight or twelve directors, with a special sticker for proof of contact with all sixteen directors. A special sticker is available for proof of contact with John Huntoon W1LVQ, manager of the ARRL, at any time on any band.

Please send $1 to cover costs of postage and handling of this award or sticker. 73 will consider it a news event of the first order when the first 16-director certificate is awarded and asks that you have a photo of yourself and your shack available, along with a brief biography and a story on how you accomplished the seemingly impossible.

Worked CQ Certificate

A beautiful illuminated certificate is available to any licensed amateur who can provide proof of contact with the editor and managing editor of CQ Magazine, K2MGA and K2EEK, both within one year of the application for the award and both through chance, not scheduled contacts. Please send $1 to cover the costs of mailing and handling. . .and good luck!

Worked Ham Radio Certificate

A new and exciting award is available for licensed amateurs who can

Worked QST Certificate

In an effort to promote activity on our amateur bands where little or none existed before, and to bring prominence to a handful of amateurs who were almost completely obscure, despite their untiring efforts to be well known, we are offering a set of awards suitable for framing. Probably the rarest of all of awards will be this gem, available to any licensed amateur who can provide undeniable proof of contact over the air on a chance, not scheduled basis, with both the editor and managing editor of QST, W1LVQ and W1CUT. Both contacts should be within one year of the application for the award. Please include one dollar to cover the costs of mailing, handling, and medication for any ill effects caused by anoverstraining of credulity by the 73 staff.

MALL DISPLAY

To Increase Public Ham Awareness–

Several radio clubs in the Southeastern Pennsylvania area have gotten together for the purpose of putting on a display of amateur radio equipment, and uses of ham radio in helping the nation and public. The display will be known as the "MacDade Mall Amateur Radio Display" and will be held Sept. 17–19 at the MacDade Mall, Glenolden, Penna.

Several MARS stations will also be in live action.

Hallicrafters Wins Cleveland FM 2-Way Contract

Lieut. Gen. Benjamin O. Davis, Jr., Director of Public Safety, City of Cleveland, points to a diagram of Cleveland's new police communications network. A vital link in the system will be the new HC-400, UHF portable radios for which Hallicrafters was awarded a contract. Shown at the extreme left: Lewis Coffey, Cleveland police chief holding the Hallicrafters HC-400 with which his policemen will be equipped; Walter Sutter, Hallicrafters vice president and general manager; Safety Director Davis; and Bob Long, Hallicrafters' Sales Manager.

provi e proo o contact wit ot t e editor and publisher of Ham Radio magazine, W1NLB and W1DTY, both within one year of the application for the award and both through chance, not scheduled contacts. Please send $1 to cover the costs of mailing and handling.

Worked 73 Certificate

If you manage to get contact and, even more difficult, get a QSL from both W2NSD/1 and K6MVH/1 you have the privilege of sending in one dollar for a certificate of questionable value which may lend some dignity to your effort. Contacts should be within on year of the application and be through chance, not schedule. Don't forget the dollar. . .we won't.

K3WAS Award

On Wednesday, 11 November, K3WAS, a military amateur radio station at Aberdeen Proving Ground, Maryland, will be operating in conjunction with Veterans Day. A very attractive commemorative certificate will be mailed to all persons who contact K3WAS on this day. The operating schedule is as follows:

50.3 MHz +.3 MHz 0001–2300 GMT
14.320 MHz ±10 kHz 0001–2300 GMT
7.280 MHz ±10 kHz 0001–2300 GMT
3.970 MHz ±10 kHz 0001–2300 GMT

To qualify for a certificate, just make two-way contact with K3WAS and send QSL card to K3WAS, Special Services Craft Branch, Aberdeen Proving Ground, Maryland 21005.

"Big Blow" Award

The Windblowers VHF Society will sponsor the 16th annual "Big Blow" contest on Saturday, September 19, 1970 from 13:00 to 20:00 EDT. There will be four stations operating on 2 meters. Certificates will be awarded to those contacting all four stations.

Location and call letters will be as follows:

W2ZDR/2 Washington Township, NJ
W2RRP/2 Sam's Point, NY
WA2ZAU/1 Topstone, CT
W2ERZ/3 High Knob PA

TAWAS Hamfest

The Iosco Amateur Radio Club is again presenting its Annual "Tawas Hamfest" in Tawas City, Michigan this year. The affair will be featuring a gigantic "swap & shop," equipment displays, banquet, Ham-of-the-Year award, and auction. The hamfest will take place on U.S. 23, 60 miles north of Bay City. Plenty of activities for the ladies, such as: boat trips, air base tour, ladies luncheons. Bring the family for a weekend of fun. Addition information: Hamfest, Box 3321, Jeff. Sta., Detroit, MI 48214.

"HISTORICAL" CONFERENCE SLATED

National Amateur Historical Radio Conference, Canandaigua, NY, Oct. 9th and 10th, sponsored by the Antique Wireless Assn. Program includes well known speakers from coast-to-coast, early transmitting and receiving demonstrations with prizes plus old equipment auction. In addition to amateur programming, there will be special events for the oldtime commercial and broadcast operator. Write for details: Lincoln Cundall, W2QY, 69 Boulevard Pkwy., Rochester, NY 14612.

The City of Clevel nd, Omo a awarded Hallicrafters Co. a contract for approximately $750,000 to supply Model HC-400 FM 2-way portable radios operating in the newly expanded 450 MHz frequency band for its police department's new communications system.

When signing the contract, Lt. Gen. Benjamin O. Davis, Jr. (U.S. Air Force, retired), Director of Public Safety, City of Cleveland, said that the Hallicrafters award was based on the "most cost effective bid" submitted for portable FM units. Hallicrafters was awarded the Cleveland portable radio contract in competition with Motorola and the General Electric Co.

The new HC-400 is small, light, and utilizes integrated circuits and the newest discrete components. Helical resonators are used instead of coils in critical rf circuits to give the high performance required in the newly assigned UHF frequency bands.

The 856 UHF type radios to be supplied (Hallicrafters Model HC-400) are an advanced communications design developed by Hallicrafters engineers. Each unit is battery operated and provides a minimum of 2W rf power output with a battery life of 8 hours at a 10–10–80% duty cycle. Each unit has 4 transmit and receive channels and is equipped with continuous tone squelch. The Cleveland version of the Hallicrafters HC-400 utilizes an external wearable speaker/microphone/antenna combination. All three functions are combined in a compact unit that can be handheld or worn on a quick-disconnect patch attached to a policeman's uniform.

The Hallicrafters HC-400 personal portable FM 2-way radio is designed to work as an integral part of the "new trend" Cleveland police communications system operating in the UHF band. The prime contractor for the system is Page Communications Engineers of Washington, D. C.

Morro Bay Award

The Estero Radio Club of Morro Bay, California, announces the Morro Bay centennial award, in honor of Morro Bay's 100th year. The centennial celebration runs from July 1970 to July 1971. Contacts for the award must be made within this period. To obtain the award, work eight stations in San Luis Obispo County, including three members of the Estero Radio Club. Any mode and any band may be used.

The members of the club include – K6TOE; WB6s: BNF, JTA, STG, TYR, PPZ, ZRR, ECM, ROG, PGK, SBH, VKN, YCH; WA6s, DDQ, DEI, FHV, GOR, MGG, QDA; and WN6s, DHS, KOG, NFB.

Send a list showing stations, times, and frequencies and $1 to WA6DEI, custodian, Box 1118, San Luis Obispo, CA 93401.

If It Ain't One Thing It's Another!

Two issues back 73 published a new-product writeup describing the FM Schematic Digest, a comprehensive sourcebook of Motorola transmitter, receiver, and power supply schematics. The only trouble with the writeup was that a price of $3.95 was quoted, while the *actual* price is $6.50. As might be expected, myriads of customers complained to the publisher that they had been overcharged. The publisher, in turn, asked 73 to rectify the situation by printing a retraction. This is it. Please, all you FM enthusiasts out there in Radioland, stop bugging the people at Two-Way Radio Engineers, Inc., 1100 Tremont St. in Boston. It wasn't their fault. Besides, $6.50 is a mighty good price for 136 extra-large pages of Motorola circuit diagrams, alignment dope, and crystal ordering info.

Heathkit HW30 twoer ground plane and beam, $50; Clegg 99er for six meters and Drake T100 high-pass filter and six meter beam, $90; antenna rotator and mast, $60. Howard Applegate, 159 Sheridan Square, Brigantine NJ 08203. Phone: YO9-266-3106.

CHARTER JET FLIGHT to SAROC. Roundtrip New York City to Las Vegas $229.00, depart JFK 10:00 a.m. January 7th. Roundtrip Chicago to Las Vegas $199.00, depart O'Hare 12:00 noon January 7th. Return January 10th. Includes meals and drinks aloft, Flamingo Hotel Room three nights double occupancy, transportation and baggage in and out of Flamingo Hotel, dinner show, midnight show, Saturday buffet luncheon, Sunday buffet breakfast, SAROC tickets, tax and gratuity. $60.00 will confirm reservation, includes one dollar service fee. Final payment due before November 25th. Flight cancellation or written request for deposit refund will be accepted until December 1st. SAROC, Box 73, Boulder City NV 89005.

ATTENTION: Galaxy V Mark 2, A.C., Console, V.O.X., $370. Gonset G-50, $150. CV-71 T.U., Lab Aligned, $65. Bill Handel K8SSY, 95 Murwood Drive, Chagrin Falls OH 44022 (216-247-6130).

HIGH-POWER MOTOROLA Handie-Talkie Motorola PT 300. Practically new. Two frequency. Tuned up and operating perfectly on 146.76 and 146.94. Includes mashbar handset with curlycord, crystals, new nicad rechargeable battery, battery charger. Puts outs about 6.5W. Receiver sensitivity 0.25 μV. A steal at $325 and the first check buys it. Manual included. Ken Sessions, 73 Magazine, Peterborough NH 03458 (603-924-3873).

TERRY COUNTRY AMATEUR RADIO CLUB will hold its 16th Annual Hamfest and Swapfest on Sunday, October 25, 1970 in the National Guard Armory, Brownfield, Texas. For those who come early on Saturday one guaranteed. Construction drawings $5.00. Box 423, Wakefield RI 02880.

RBB-RBC MANUALS, New, $5.00; Used, $4.00. OS-8 oscilloscope manual, $3.00. Some QST 1929, 30, 31, etc. Radio 1939, 40, 41, etc. Write for list. James W. Holloway W6LFL, 2027 Harton Rd., San Diego CA 92123.

SAROC January 7—10, 1971, Flamingo Hotel Convention Center, Las Vegas, Nevada. Sponsored by Southern Nevada ARC, Inc., Box 73, Boulder City, Nevada. Advance registration $14.50 per person accepted until January 4, regular registration at door, includes Flamingo Hotel Late Show and drinks, Sunday breakfast, cocktail parties, technical seminars and meetings, ARRL, DX, FM, MARS, QCWA, WCARS-7255, WPSS-3952, and WSSBA. Ladies Program. Flamingo Hotel SAROC room rate $12.00 plus room tax, per night, single or double occupancy January 3 thru 12, 1971. Mail accommodations request to Flamingo Hotel. Mail advance registration to SAROC. W7PRM, Club President. W7PBV, SAROC Convention Chairman.

GREENE. . .center dipole insulator with. . .or. . .without balun. . .see November 73, page 107.

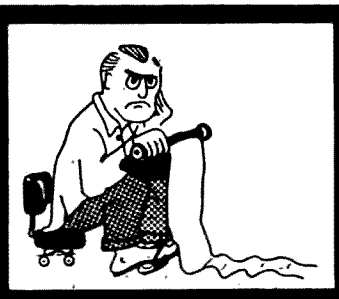
SELL or trade for ham equipment: H/P micro-wave instruments; 415B $50, 416B $75, 430C $75, plus shipping. WA8JEH, 23 Coolidge Ave., Columbus OH 43228.

HALLICRAFTER HT-33 kW linear (needs 2 tubes) $75, HT-30 Exciter $75, Drake 1A rcvr. $100, all for $200. Phil Windolph W9NEP, 10737 S. Michigan, Chicago IL 60628.

SELL: Two Synchro Tape Machines (Remington Typewriter/Friden Tape/Card Punch and Reader) $150. Operation instructions and manuals for Friden units only. Some tape and cards included. Complete description in late 1968 issues of 73. Tektronix 511AD $95. Tektronix 514AD $150. Manuals, probes, and some spare tubes included.

30 WATT SSB TRANSISTOR

A new single-sideband transistor furnishing 30W PEP across the 1.5 to 18 MHz band is announced by TRW Semiconductors. The new PT6738 has a gain of 13 dB and intermodulation distortion guaranteed 30 dB or better. Operating voltage is 28V. The unit is in the TO-59 package which is compatible with the TO-60. The new transistor is a product of TRW Semiconductor Division, Communications Transistor Plant, 14520 Aviation Blvd., Lawndale, Calif. 90260.



Representatives from five major distributors of Signal/One's Model CX7 transceiver inspect the new radio in a familiarization seminar at the Signal/One facility in St. Petersburg, Fla.

From left are Otto Hagendorff of Harrison Radio Corp., New York City; Park il Young of Henry Radio Stores, Los Angeles and Anaheim, Calif.; Signal/One's Charles Brock; Doug Murray, owner of Amrad Supply, Inc., Oakland, Calif.; Miles Cundy of Amateur Electronic Supply, Milwaukee, Wisc.; Signal/One's Amory Planchard; and John Capone, owner of CW Electronic Sales, Denver, Colo.

The Signal/One program is a part of the Data Communications Group of Electronic Communications, Inc.

The CX7, described as a "deluxe integration station in a single compact package," incorporates many new design features, most of which stem from the application of advanced aerospace electronic technology to the amateur radio field.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

A note from one of the officials running the ARRL National convention in Boston explained that Huntoon again has forbidden them to allow anyone from 73 to appear on any program.

There being more than one way to skin a cat, we have arranged to have an auditorium room at the convention in which to run our own program. This is more than sour grapes, judging from the number of letters we have had asking if we were going to be able to show my slides of King Hussein, if Ken were going to be able to organize an FM repeater forum to coordinate action for getting the proposed FCC regulations straightened out, etc. There are a number of things that should be brought up for discussion at the National Convention and we intend to bring as many up for discussion as possible.

To those of you familiar with the usual ARRL open forums, let me say that the forums we organize will not be the rigged affairs that you have experienced in the past. I have yet to see an ARRL forum that didn't appear to be meticulously planned with the end of preventing the members from asking any embarrassing questions.

If you have any ideas for forums that would be of benefit to our hobby please take the time to work out some details on your ideas and send them to me.

The schedule of talks in our room . . . room 437 . . . will be available at the 73 booth. Among some of the talks and forums being scheduled are the following:

DX coffee klatch
160–80 DX forum, KV4FZ moderator
Foreign visitor get-together, YO2BO moderator
Forum: Where do we stand with the ITU?
Forum: Do we need more phone allocations?
FM coffee klatch
Forum: FM repeaters and the FCC
Forum: FM the state of the art.
Forum: Do we need a Washington lobby?
Forum: 146.76 or 146.94 as a repeater output?
Forum: DX
Slides: Trip to Jordan and JY1
Slides: Visit to Arecibo and the big dish
Slides: YA-YK-YI-EP
Slides: FK-VR2-5W-KS6-FO
Forum: Mandatory tone for repeater control?
Forum: VHF
Forum: RTTY
Forum: Moonbounce
Forum: New blood for amateur radio?
73 boosters open house (cider–doughnuts)
Forum: Incentive licensing?

It is hoped that all sides will be present for the open forums so that the best thinking of everyone involved can be used to provide solutions to our problems. We plan to record these forums and present the highlights of them in future issues of 73. We will do what we can to see that a representative of the ARRL is present at all forums to provide an explanation of the official ARRL explanation for what has been happening.

Since most of the action of the convention is on Saturday we have scheduled all of the activity on our program for this one day.

Schedule Canceled

In the August issue of 73 I announced that I would be standing by as nightly as I could on 14.300 at 0200 GMT for anyone with any traffic for me, particularly for news items that might be of value for the news pages.

After trying this scheme for a little over a month and meeting the schedule most nights, I can see that it is time to call a halt to this madness. The interference in this General part of the band is beyond belief and more than I care to continue to face. Sure, I can hear the fellows in there calling me, but the noise from other stations is so bad that I can't even get call letters through unless the caller has a kilowatt and a good beam to back him up.

The General class operators who are trapped up in that 75 kHz of the band have more patience than I. The Advanced part of the band is relatively free of interference and the time is rare indeed when I can't find a reasonably clear channel there for working DX. I suppose that it is a lot easier to put up with the mess in the General section of the band than to try and change the band.

It is not likely that I'll be missed too much on 14.300 as one signal more or less on the channel

Leaky Lines

1 DANIEL LANE, KINNELON NJ 07405

According to a report in a recent issue of Popular Electronics, one of the CB clubs has established an office in Washington for lobbying purposes. The item also states that a nationwide CB organization is probably in the offing, to be coordinated into a program through which they hope to influence the actions and attitudes of FCC. They claim to have an ex-White House staffer and several Texas Congressmen interested in Citizen Band Radio.

There can be little doubt that such an organized lobby, if properly financed and well connected politically, can become a strong force in representing the more than 875,000 persons licensed in that service. But what about us hams? What will happen to the Amateur Radio Service if the CB interests succeed in gaining an inside track, and we continue to go on, living in a fool's paradise?

At 73, Wayne has been advocating a change in perspective for a long time. There are many valid reasons why the American Radio Relay League ought to change its inflexible opposition to the idea of representation in the nation's capital. It is no longer enough to maintain a *laissez faire* attitude toward this necessary change on the sole ground that we must preserve a tax-free status for the organization. While it may be perfectly true that the League saves a great deal of money through this posture, if we were to lose prestige in the eyes of legislators and members of the FCC, merely because of our failure to propagandize (and yes, wheel and deal) with persons who simply do not recognize that there is a vast difference between amateur radio and Citizen Band radio, we are a cinch to wind up holding the smelly end of the shaft. No matter how exalted the position in government a person may hold, he cannot be ex-ected to suck the true picture from his thum There are some very intelligent people who still do not know that we are different from CB'ers, and they actually think that persons who run the little five-watters are ham operators. They simply have no idea that we are a group which participates in a wide spectrum of public service activity . . . and how in the world could they be expected to know the truth if nobody points it out to them?

It has become more urgent than ever for the League to get off its duff and begin to do something about this. We can straighten out our image in short order if only we forget about our own exalted opinion of ourselves. We must get over the idea that we are above getting our hands soiled . . . that we are too good to engage in struggle with our adversaries . . . that we must not show bad manners by sinking to the low level of others. There is absolutely nothing to be gained by sneering and making snide remarks about the 11 meter bunch. While we are scoffing and ridiculing them among ourselves, they might very well be getting some naive Congressmen to pressure FCC for additional frequency grants, and I would just like to ask you, where would that increased spectrum come from? I'll give you three guesses!

We cannot rely upon "The Ham's Wide Wide World" to do the job. It does some good, of course, but it's simply not enough. Ten, twenty, or thirty films like it would also be good, but would not be enough to handle the job. We have got to embark on a much broader program of public education and orientation, which will penetrate into the consciousness and awareness of this entire country. We have got to make sure that everyone in America recognizes that amateur radio contributes toward the general welfare and health of our nation, and it is a viable and indispensable part of our system. We must point out, so that all our people know it unmistakably, that ham radio is not a toy or an idle pastime for a set of superannuated playboys, retirees, and young kids. There are far too many folks in this country who think that ham radio is like stamp collecting, bowling, fishing, kite flying, and other such recreational hobbies. They must be made to realize that amateur radio is a meaningful activity which is vital and necessary to the ongoing development of our society. This can only be accomplished through public education on a wide and universal scale.

It does us little good to proclaim to each other, either verbally or in our own ham publications, which are rarely read by outsiders, how much good we do in programs like AREC, RACES, MARS, or in all our other work. We already know all of that. We don't need convincing. It is the general public and those who represent them in government who must be made aware of it! If we fail to get off our fat behinds and do some missionary work, we may find

(cont. on page 94)

There's an ugly rumor floating around about an idiotic FCC interpretation of what constitutes misuse of spectrum; and if the rumor is proved true, the new bad guys will be the Feds in Washington. And the good guys will include Wayne Green and John Huntoon, as well as all the ham operators who participate in service and medical-aid nets.

The to-do started when the FCC lowered the boom on the eye bank net. According to the Feds' new interpretation of an overapplied ruling, such operations are now illegal. The FCC dropped a note to some of the fellows in the eye bank net and advised them that their hamming was "for the use of" an organization, and was thereby an improper operation.

At the League, Huntoon got wind of the flap and protested to the FCC. The West Coast DX Bulletin also made noises of dissent. But so far the cries have gone unheeded, and the eye bank net – as well as thousands of other service groups – stands on the verge of disbanding. Huntoon voiced his comments to ARRL directors in a general letter last month, stating that the FCC is in effect actually reversing its prior policy of encouraging service organizations.

"These newest interpretations," Huntoon said, "strike at the heart of organized amateur radio in denying our right to continue to engage in such activities as voluntary communications for most boat races, parades, car rallies, charity drives, election results, eyebank network, and the like. . .

And from the West Coast DX Bulletin came the comment: ". . . it would be wise for every amateur – DX'er or otherwise – to watch this matter, keep informed of developments, and support the ARRL in its protests to the FCC."

To give the devil his due, I must say that in this issue, the League must be supported. John Huntoon is right in his reference to the new threat to organized ham radio. The FCC must be made to see that these service functions and organizations are the stuff that hamdom is all about. The consideration that I think should be foremost in the minds of the Feds is the one stipulated most clearly in the FCC rules – about the principal purpose of amateur radio being for the convenience, necessity, and in the best interest of the public.

If the eye bank net is not in the best interest of the community, how can amateur radio itself be? Even the *Saturday Evening Post* has acclaimed the amateur eye bank net for its service to humanity. In a comprehensive story on the workings of the net, Max Gunther's Post article told of how the hams work with surgeons to win the race against blindness. The story goes, in part:

Early in the morning of May 2, 1963, at the Indiana University Medical Center in Indianapolis, a man died of a heart ailment. He was 57. During his lifetime he had become interested in new medical techniques for saving sight, particularly in the fact that parts of the eye can be transplanted from one person to another. Like a growing number of Americans, he had authorized surgical use of his eyes after his death.

The dead man's eyes were promptly removed, sterilized, packed in small glass bottles, and carried to the Indiana Lions Eye Bank in the same building. If, within 48 hours, an eye patient needen them, these eyes could be used. After that, they would rapidly deteriorate.

Later that morning in Iowa City, Iowa, a man visited eye surgeon Dr. Alson Braley. The patient was a dark-haired, handsome young engineer who worked for the Maytag Company in Newton, Iowa. Since his boyhood his left eye had suffered from an inflammatory condition which had damaged the cornea, the transparent outer covering of the eye. On this May morning the eye had suddenly become very painful. Doctor Braley found that the cornea had ruptured, and rushed his patient into the University Hospital. If the eye were not repaired before the day ended, it would be lost.

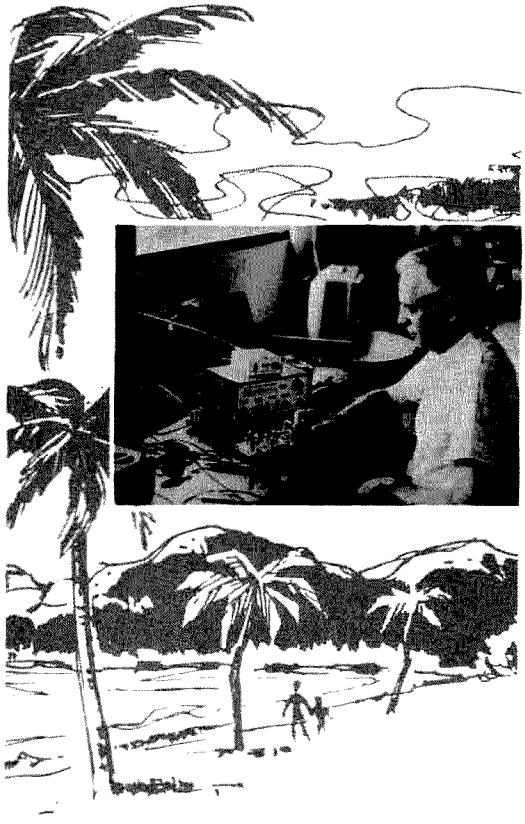
Doctor Braley's job was to cut out the damaged section of cornea and replace it with a piece of healthy cornea from a donor's eye – if he could find one. He telephoned the local eye bank, but they had no fresh eyes available that day.

Local eye-bank workers might have spent all day telephoning the 80 other eye banks scattered across the nation, and it could easily have been too late by the time the eyes were located in Indianapolis.

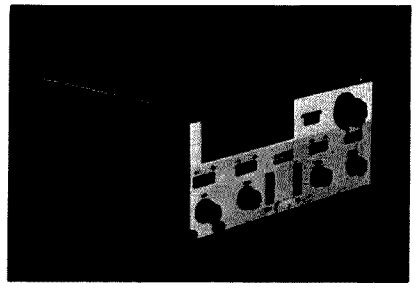
Fortunately for Doctor Braley's patient, a more effective link existed – a coast-to-coast network of amateur, or ham, radio operators who make it their hobby to provide emergency communications among the far-flung eye banks.

The staff of 73 joins the staff at ARRL headquarters in an appeal to the FCC to give fresh consideration to federal rulings and official interpretations. All amateurs working in public service and all amateurs who believe that public service is vital to the ultimate preservation of our hobby should voice their opinions to Mr. Bill Grenfell, FCC, 1919 M St. N. W., Washington, D. C. 20554,

. . . K6MVH ■



he worked the world.



Mr. John H. Thompson, W1BIH/PJ9JT, recently packed his Ten-Tec Power-Mite PM 3A transceiver into a suitcase and headed for the Coral Cliff Hotel, Curacao (Netherlands Antilles). From there he worked the world.

"Final tally on the PM 3A results at PJ9JT are 261 QSOs on 14 MHz and 41 QSOs on 7 MHz for a total of 302. This includes 32 different countries in 5 continents. I operated only with the PM 3A on 7 and 14 Mc. CW. No contacts were set up first on high power, nor was any auxiliary receiver used. It was all done with the PM 3A. Of course I had a FB location and the call didn't hurt. Among the DX worked were five VKs, a ZL, VU and 4X4. Only Africa was missed and I did get a PJ? response from an EL. The batteries, a pair of 6V lantern batteries in series, lasted the entire operation and showed no signs of failing. Some comments from stations worked:

W8KIT: 'Congrats on that signal with real QRP'
WØOPK: 'Unbelievable'
W5IUW: 'Ur really busting my ears'
W3KR: 'Boy, ur 5 watts FB here on my attic antenna'
W4KC: 'Did you say 5 watts?'
W2GA: 'Boy, ur rig doing FB'
W4YWX: 'Unbelievable — if I didn't know you I'd swear you're pulling my leg because ur hitting 20 DB'
K3CUI: 'Are you really running only 5 watts? FB'
OK1AOR: 'Sigs 589 FB'
K6IC: 'Your 5 watts sure good here'
UK2KAF: (ex UP2KNP): 'Ur low power sure doing FB'
K4ZA: 'Ur sig has real punch'

I did other hamming, making some 400 contacts on the other bands, both CW and SSB using high power equipment. Could have made many more QSOs in the same time using the high power rig but it wouldn't have been half the fun."

Power-Mite PM 3

UNDERSTANDING AND USING INTEGRATED CIRCUITS

The transistor was born amid predictions that vacuum tubes would soon disappear; then, some ten years ago, the first integrated circuits led to speculation that both tubes and transistors would be replaced. While neither of these predictions has yet been completely fulfilled, the last few years have seen substantial shifts towards exclusive use of ICs. It is becoming increasingly profitable for equipment manufacturers to substitute inexpensive, complex "subsystems" for the array of components formerly used, eliminating at the same time much of the assembly work.

For amateur radio, particularly the "homebrew" man, the wide availability of cheap ICs opens up new possibilities. Commercially built ham equipment should simultaneously improve in performance and decrease in cost. As spectrum space becomes more precious, and more sophisticated modulation methods become necessary, ICs will allow uncomplicated design and construction of transmitters and receivers which would have once caused casual weekend experimenters to give up in despair.

What Is an Integrated Circuit?

There's no reason to be mystified. An IC is simply a garden variety transistor circuit, in which a number of transistors,

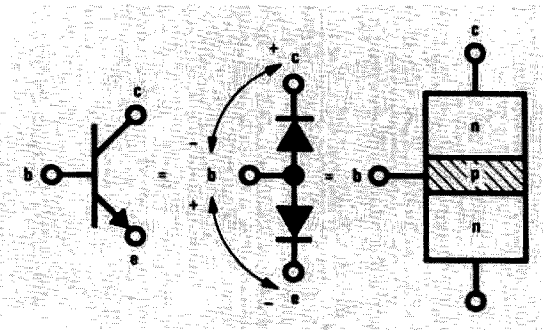

Fig. 1. An NPN transistor as two back-to-back diodes.

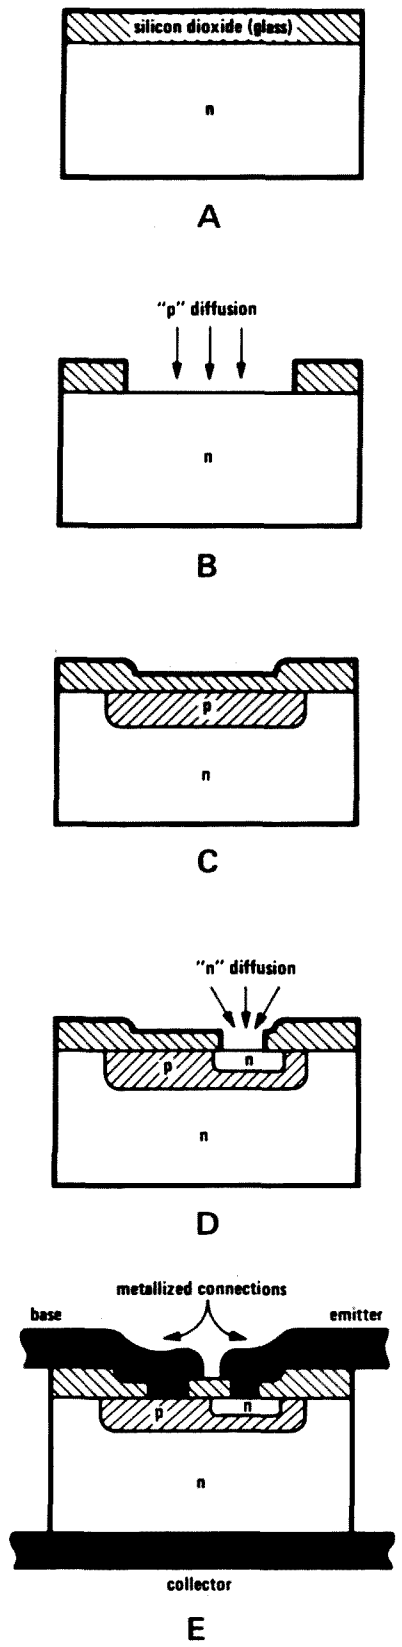
diodes and resistors have been made at the same time, by photographically and chemically treating a piece of the base transistor material – silicon. The IC, or microcircuit, is a natural outgrowth of the process used to make single transistors, so let's use the transistor as an IC primer. In its simplest definition, the NPN transistor



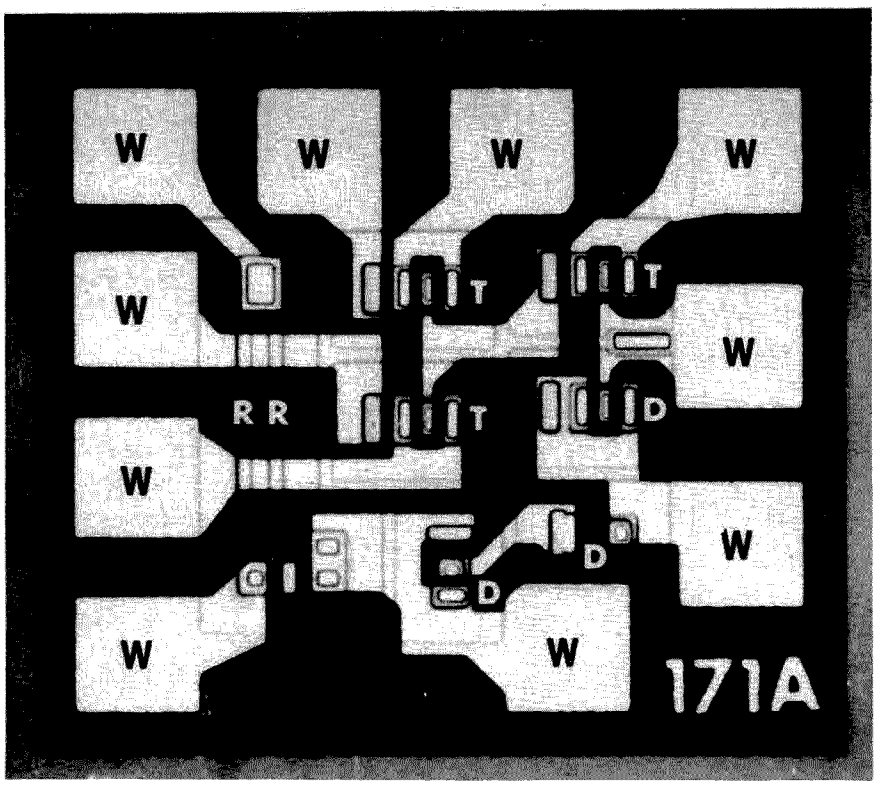


Fig. 2. Construction of a silicon NPN transistor (cross-section view).

of Fig. 1 consists of a forward-biased diode (emitter–base junction), and a reverse-biased diode (collector–base junction), which can be made from a slab of silicon by "diffusing" P- or N-type chemicals, in a high-temperature furnace, into selected regions of the slab.

Assuming that we start with a slab already containing N-type chemicals, Fig. 2A, and chemically "grow" a thin layer of glass (silicon dioxide) on top, the glass layer is now a shield against penetration of the slab by other chemicals. Using the same kind of photo-etchihg techniques used in the making of newspaper type and photo plates, we make a "window" in the protective glass, Fig. 2B, and then place the slab in a furnace containing P-type chemical gases. The result is Fig. 2C, a "diffused" region under the window in which the majority of atoms are now P-type, plus a regrown layer of glass over the window. A second window, smaller than the first, is opened, and the process is repeated in an N-type furnace, giving the structure of Fig. 2D. Windows are then opened, and contacted by a thin layer of aluminum, for each of the three regions in the slab, Fig. 2E. Attached to wires, and brought outside a can enclosing the slab, these three regions become the collector, base, and emitter. We now have an NPN transistor!

Why make just one transistor? Why not use a photo-etching process that makes many transistors, side by side, on the same slab? This is in fact how most single transistors are made today. Starting with one N-type collector region, many bases and emitters are diffused, with the resultant thousands of transistors, being cut apart afterwards and put in individual packages.

Suppose we want to build other components – for example, a resistor – using the same processing steps employed in making transistors. Why not use the built-in resistivity of the chemically treated silicon as a resistor? And why not cut apart the transistors in interconnected groups, rather than into individual pieces? One problem exists: isolating one element from another. Remember, in a slab, or "wafer," of NPN transistors, all collectors are in one

This photomicrograph of an IC rf amplifier shows NPN transistor elements (T), diodes (D), resistors (R) and the wire bonding pads (W).

region, and are thus shorted together. The solution is a fourth, P-type region, separating each transistor or resistor region (Fig. 3). If we bias this "isolating" region so that it always forms a reverse-biased P-N junction with everything it surrounds, each "component" in the IC will be effectively isolated by a nonconducting, open diode. We can now form any combination of transistors, resistors, and diodes we like, simply by choosing which "windows" we open at each step in the fabrication process.

What Are the Advantages of ICs?

Economy – Since we must go through the photochemical process to make transistors anyway, it costs very little more to make several of them; putting many transistors in one package is more economical than separating them. In the long run, an IC gives a lower "cost per transistor" than a discrete transistor circuit.

Ease of Use – Most of the signal processing and dc biasing is done within the microcircuit, so less wiring is needed to bring signals in and out of individual

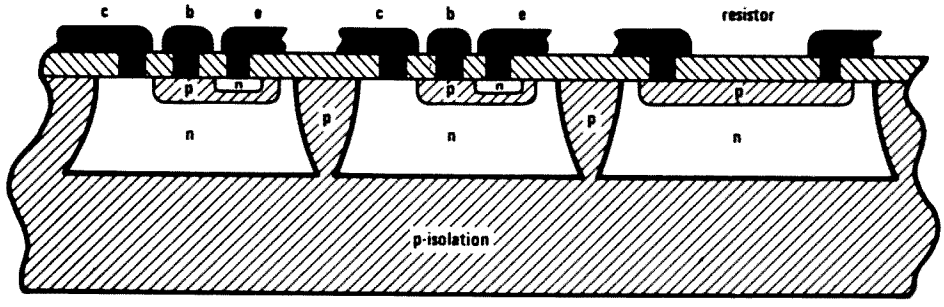

Fig. 3. Cross-section view of an IC, showing two NPN transistors and a resistor.

uses the NPN collector region as base, with P-type emitter and collector formed by two adjacent diffused-base regions. Current flows sideways, or laterally, from emitter to collector. Since the width of the base

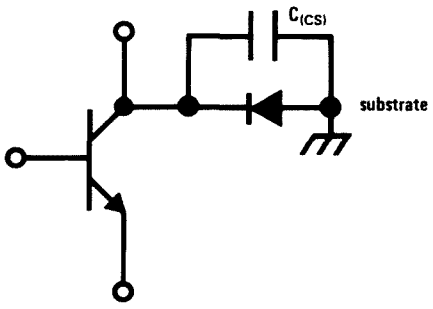

Fig. 6. The "Parasitic" collector-substrate diode.

region is much wider than used for an NPN, the lateral PNP has poor frequency response and a low beta. Thus, lateral PNPs are not used as gain stages, but only as dc level shifters, where necessary. The substrate PNP uses the same type of emitter and base as the lateral; however, its collector is the P-type isolation region, or substrate, which limits the usefulness of this transistor, since its collector is always grounded, and its characteristics as poor as those of the lateral PNP.

Medium-power NPN transistors are now practical; they take up a great deal of chip area because of the need to spread their dissipation over a larger region. Their collector saturation resistance is not as good as very inexpensive "discrete" power transistors, because IC collector contacts are necessarily made from above, while ordinary power transistors, which don't have isolation regions, have bottom collector contacts, with a shorter current path, and hence lower resistance. For most practical designs, an IC can handle power outputs to a watt or so, but must drive an external power transistor to obtain power levels. This also keeps IC power dissipation within the limitations of its small package.

Parasitics – Here is where the actual characteristics of an IC depart in unexpected ways from those of the same circuit in discrete form. The culprit is the P-type isolation region, which separates the various IC elements; it is a reverse-biased PN junction (Fig. 6), which is assumed to be an open circuit. But such a junction produces a parasitic shunt capacitance from NPN collector to ground, which can deteriorate high-frequency performance of the IC. While IC schematics rarely show this PN junction, it must be remembered by the user who applies supply voltage other than those recommended; since the substrate is commonly connected to the most negative point in the circuit, normal operation does indeed keep it reverse-biased, but an attempt to operate an NPN collector more negative than this voltage will forward-bias the junction, drawing possibly destructive currents. Finally, this seldom-mentioned junction can produce undesired substrate PNP action, or even act as an SCR.

Recalling that one definition of a transistor is that it contains a forward-biased and a reverse-biased junction, it can be seen that if the collector–base junction of the NPN is inadvertently forward-biased, it will form the base–emitter junction of a substrate PNP whether we like it or not. Moreover, this condition produces exactly the same trigger condition in the four-layer *NPNP* IC structure as is used to turn on a four-layer SCR. Under some circumstances, this produces "latchup," which holds until the supply is turned off, or draws enough current to damage the IC. In properly designed ICs, used according to manufacturers' recommendations, parasitic problems will not arise. Experimenters, using nonstandard external hookups, however, may find "parasitics" the explanation for the IC's unexpected behavior.

Conclusion

We've peered inside the marvelous, widely acclaimed IC, and found it to be a logical extension of known circuit designs and transistor fabrication techniques. It has a few peculiarities, but offers convenience, performance, and economy in building all types of ham equipment. A basic understanding of what goes into an IC, its advantages and inherent limitations, will prepare us to look at available ICs, and learn how to put them to work.

. . . W6DNS ■

transistor stages, or to interconnect bias voltages.

Performance – As we've seen, there's nothing magic about the individual transistors used in an IC; if anything, they may not be quite as good at high frequencies as their discrete counterparts, because of the capacitance to the "isolation" region. Their real advantage in performance is that we are no longer limited to designing circuits to use a minimum number of expensive transistors; we can design a better circuit that uses four or five times as many transistors, at less total cost than the discrete circuit. Moreover, interstage coupling and capacitance is much less of a problem than with "discretes," because of the microscopic lead lengths between components. Finally, because all parts of the IC are made simultaneously, by accurate photographic techniques, excellent component matching is guaranteed. For this reason, integrated circuits are available which simply are impractical using single, hand-matched transistors and resistors.

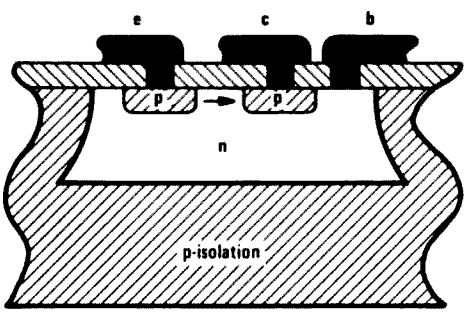

Fig. 4. Lateral PNP (cross section).

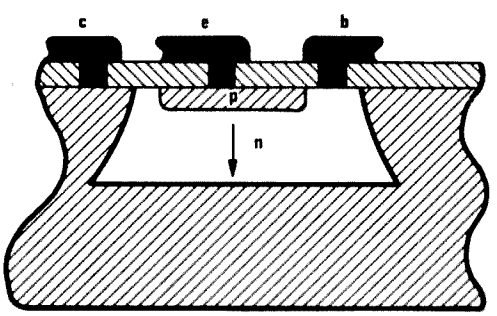
What Are the IC's Limitations?

Large Component Tolerances – manufacturers, despite their most careful controls, cannot prevent a wider variation in resistance, transistor beta, etc., than would be allowed in conventional circuits. A 1 kΩ resistor might well be 750 kΩ on units from a given production run, and as high as 1.25 kΩ on the same type of device from a different run. This was considered a problem in the early days of ICs, but designers soon discovered circuit techniques which overcame uncontrolled tolerances. While *value* of monolithic elements varies from run to run, the *ratio* of adjacent components is very accurately controlled. For this reason, most ICs are designed to rely mainly on ratios, rather than component values.

Limited Types of Components – Since the basis for the IC process is the same as that used for NPN silicon transistors, we might expect NPNs to be the best components resulting from that process. Adding resistors, diodes (which are really transistor base–emitter junctions), and zener diodes (which are reverse-biased base–emitter junctions), there is a much more limited selection of practical components available to the IC designer than with conventional circuits. Capacitors of any reasonable value take up too much chip space, which increases the IC's cost. A 0.01 μF capacitor, made either by using the capacitance of a large, reverse-biased PN junction, or by using the "glass" layer as a dielectric, with a metalized top plate would be several times larger than the largest ICs commercially made today. Thus, when a capacitor is needed for an IC, it must be placed external to the IC itself. In an attempt to minimize the number of external capacitors, many new ICs depart from the usual RC-coupled interstages, and are instead completely direct-coupled.

Similarly, inductance on a chip is impractical, so that ICs designed for tuned amplification generally require external tuned circuits.

While PNP transistors are used, they are not capable of nearly as good performance as NPNs, since the chemical processing is not optimized for them. Two types of PNP are available: the *lateral* PNP (Fig. 4) and the *substrate* PNP (Fig. 5). The lateral PNP



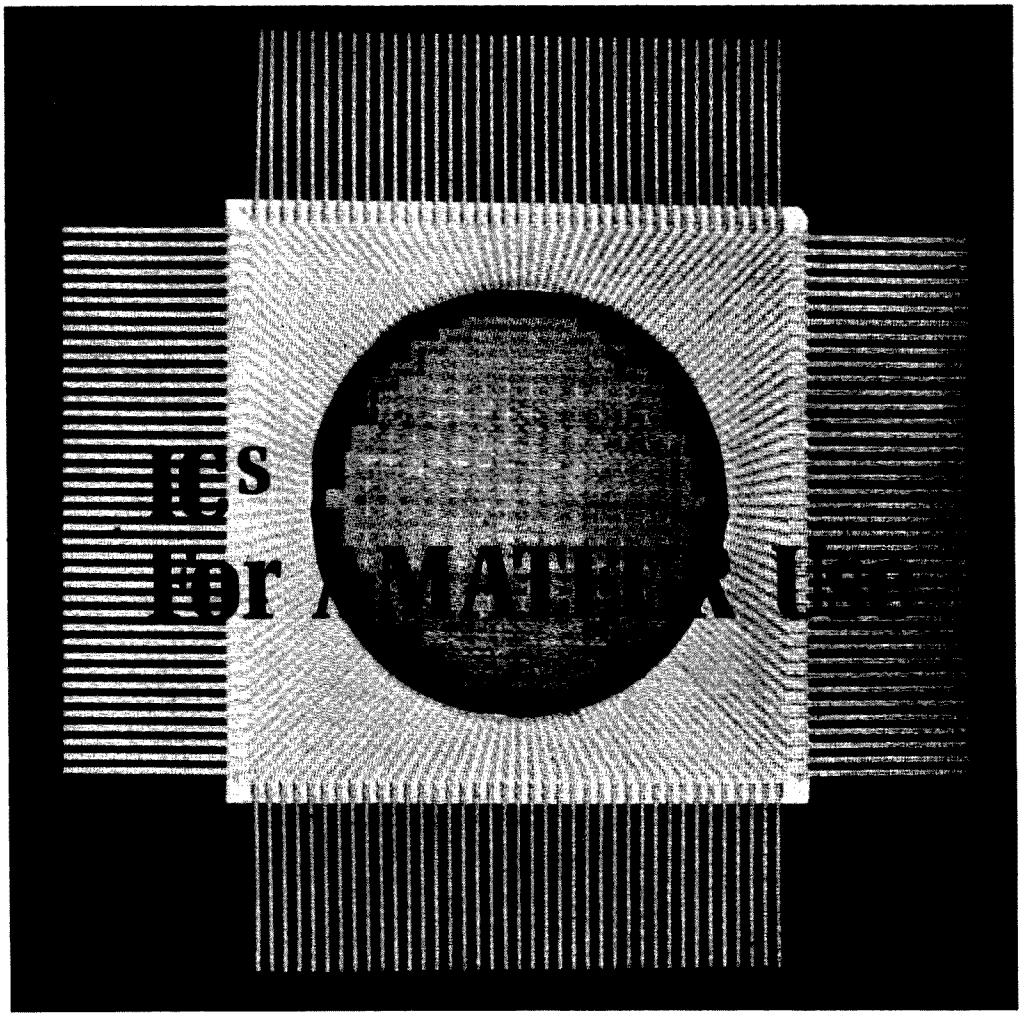


Fig. 5. Substrate PNP (cross section).

Bill Hoisington K1CLL
Far Over Farm
Peterborough, N.H.

You may not like parts of this article, but then a lot of real life isn't all that likable either. I'm just going to put down my viewpoint of ICs as related to amateur use at the present time as I find them. Some can be very useful, and some are not so useful, even though they work well for their original purpose.

I hope this article will help you decide which kind to experiment with, and how to tell the useful ones from the kind that are good for computers only.

Integrated circuits are simply very small transistors, diodes, and resistors, constructed on tiny dice, sometimes called chips, of substrate material.

Capacitors and inductors are not generally included in these devices; therefore, in communications systems the external components are often many times larger than the IC itself. The benefits of ICs can be considerable, however, as in an example such as the HEP 590, which has high gain, low internal feedback, and absence of detuning effect over the entire avc range.

Computer ICs

This is where the whole thing started, and it was a fascinating story, for the science of electronics at least. In a computer there is a tremendous need for hundreds, thousands, and millions of memory cells, switches, gates, adders, shift registers, "scratch" pads, inverters, counter–dividers, delay lines, digital-to-analog converters, analog-to-digital converters, flip-flops, buffers, comparators, parity generators, current drivers, differential and operational amplifiers, binary

decoders, and a host of other device types – all of which are geared not for the ham but for the computer specialist.

In spite of the cumbersome logic that early Scientific American articles declared to be about ready to topple from sheer unreality, some computers *can* do things that cannot be done by men, such as computing an astronaut's course correction in a few seconds, solving vast and complex urgent equations also in seconds, etc.

But what concerns us as amateur–experimenters building new amateur communications equipment is the IC itself. Today's computers use, as one example, a 14-pin flatpack about ¼ in. long by about 1/8 in. wide, and *very* thin. The particular one I have in mind contains some 32 transistors and is the great-grandchild of a two-transisor flip-flop multivibrator, which can "stand on one leg or the other but not on both." To make the pesky little thing foolproof, they included a variety of "constant-current transistors, lockup prevention transistors, phase reversers, (which reverse the "truth table"), and heaven knows what else.

I did detail all the functions in there at one time, a few years ago, and believe it or not the specs on this thing do include a truth table. They do work, even though there is not one capacitor in there. Everything is direct-coupled. With 5V at several hundred amps total on a computer power supply they're happy with IV in the off state and 4.5V in the on. They work fast, too, like being clocked (pulse driven) by 2,10, or 20 MHz oscillators, or even higher as each year goes by. Yes, this does mean exactly what you're wondering about 2,10, or 20 *million* pulses, or "clicks of the clock" per second.

So the computer can work fast – so fast even that they're now worrying about the time it takes for a signal to travel over printed ribbon connectors from one tray to another. Sound familiar? Like short leads at VHF and UHF?

MSI and LSI

Just another word to let you know that the big manufacturers are not content with just 30 transistors in an IC. No siree!

Medium-scale integration, or MSI, which is just a way station, puts a lot more than 30 devices – really invisible to the human eye now – in that little can.

Large-scale integration (LSI) really gets to be high-density. I have one with 156 leads and 774 announced functions on a single chip.

There are manufacturers who make ICs that amateurs can use, as well as some transistors for TV front ends that look great for VHF and UHF.

Adding another transistor to the design of a chip is a matter of around 3¢ or 4¢, maybe even less today. You draw up a set of masks and reduce them down photographically to where each individual transistor-to-be cannot be seen at all except with a good microscope.

Then these masks are used one after the other to diffuse various materials going onto the chip, such as properly doped silicon, aluminum, gold, etc. – and eventually you have a wafer with fifty or a hundred, or some other larger number of ICs on it. One transistor more or less is thus only a matter of dividing the time involved in drawing it once – plus the engineering time of thinking about how to do it, and how to test it afterwards. This is one of the main reasons for the seemingly large numbers of active devices in some ICs. If there's any possible advantage, in they go! Why not?

Communication ICs

Here is a different story right away. Practically every "radio set" for communication work that I've ever seen or heard of has coils in it (or at least resonators if you go to UHF and microwaves). Now in a little flatpack only a few mils high how are you going to put in any tuned circuits? The answer is, of course, you don't. They go outside. So now where are you? You're up against a conflicting set of requirements.

There are some "natural" divisions of rf, af, and i-f circuitry where attention must be paid to the proximity of the components, as illustrated in Fig. 1. Shielding, or great care, or both, should be used at these points. They are;

1. Rf amplifier input–output.

2. I-f input–output, in particular from the diode region back to the front end –

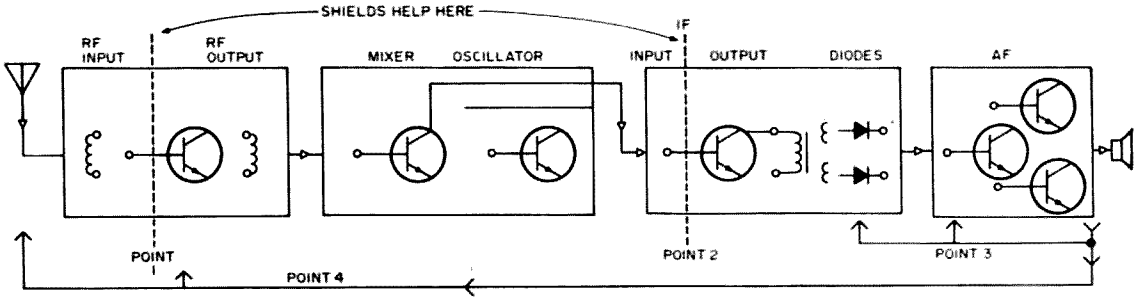

Fig. 1. Block diagram of typical receiver showing "trouble spots."

particularly touchy on certain i-f harmonics.

3. Af input–output.

4. Overall feedback from the af output to the front end, even speaker to antenna, this being often just a loopstick and close by.

In the following rf–i-f IC example you will see that certain things *can* be done on those tiny chips which are very interesting – not only for i-f work but for rf also.

Motorola's **HEP 590**

Motorola has a very interesting IC device for high frequency amplification, the HEP 590. Two outstanding advantages can be noted: low internal feedback, even when using the maximum gain of over 30 dB, and large avc action without detuning of the circuits

It is packaged in a 10-pin can some 5/16 in. in diameter. The leads can be soldered or inserted in a socket. The present suggested net price is $3.99, which is quite low considering what it accomplishes.

How the HEP 590 Works

Figure 2 shows the internal schematic. When avc voltage is applied to the base of Q2, Q3 is turned off and the ac gain will be at a minimum. This action takes place *without* noticeable change in the operating point of Q1, whose input impedance remains constant, with very little detuning effect on the input tuned circuit even with maximum avc voltage on Q2.

The configuration of Q1 and Q3 reduces the internal feedback to a low figure, which is generally immeasurable up to several hundred megahertz. With the 30 dB of gain obtainable at 60 MHz, this is a great advantage.

Diode D1 is for dc biasing of Q1, under conditions of varying temperature. Being laid out on the same silicon die as Q1, their currents will be closely similar, even with severe changes in temperature, with consequent dc stability.

The noise figure of a two-transistor pair is lowest when the input device uses the common-emitter connection. The second device will then have little effect on the noise figure.

The actual measured gain at 60 MHz is over 30 dB in suitable circuits, which consist of no more than tuned and impedance-matched inductors.

By the use of two of these devices in cascade, bandwidths of over 10 MHz may be obtained at 60 MHz, which shows considerable possibility for amateur microwave amplifier service.

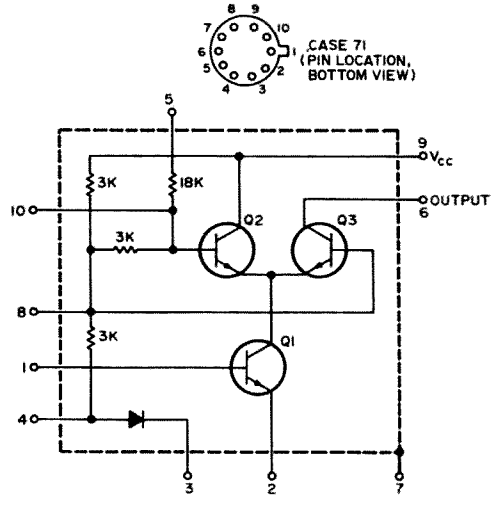

Fig. 2. Internal structure of Motorola's HEP 590 and pin identification data.

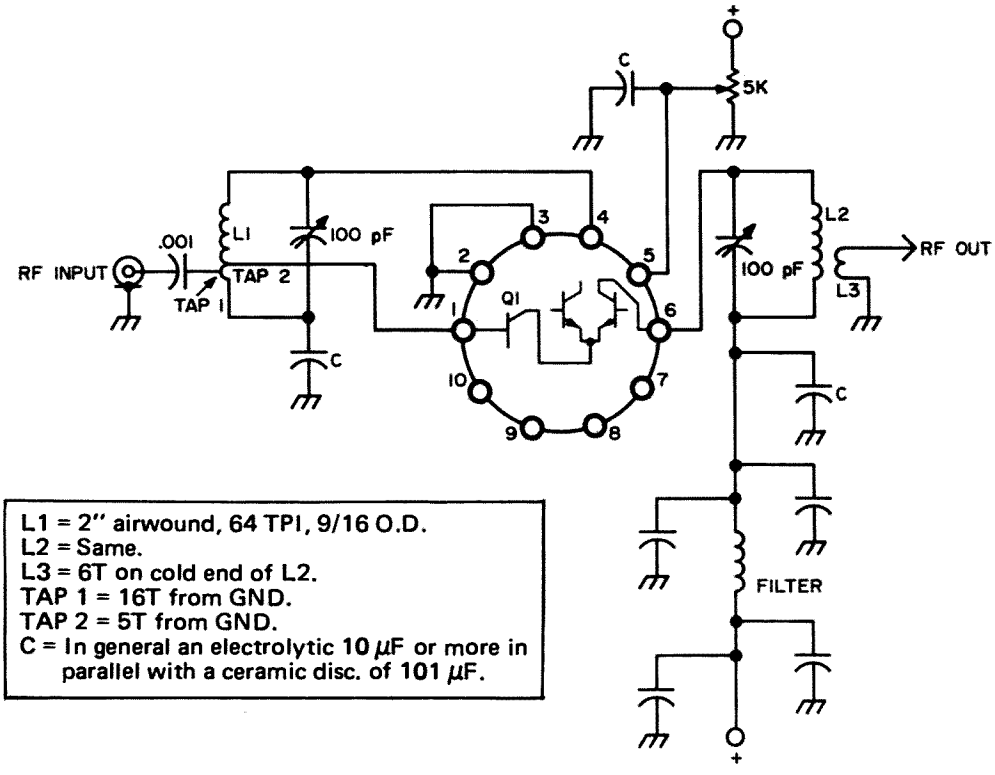

Fig. 3. 40m amplifier built around a HEP 590.

The **HEP 590** on the Breadboard

The 40 meter amplifier circuit of Fig. 3 was set up on a copper-clad baseboard with soldered connections to terminal strips. The antenna was brought in to a connection on L1 at 16 turns from the cold end and the 590 input lead (pin 1) tapped at 5 turns. The 100 pF capacitors (C1 and C2) are too large for in-band operating units but are all right for experimental use.

Manual control of the gain was accomplished with the 5 kΩ pot, avc tests to be done later in i-f service.

The output of the device (pin 6) was connected to the top of L2, and 6 turns of small wire wound around the cold end.

I started out with loose-coupled antenna, base input, and output link, but soon discovered this is *not* the way to go with the 590. It likes *lots* of coupling, on both input and output. When this was done, the really large gain of the device became evident. Various signals from 80 to below 40 meters sounded like reception with a superhet receiver (except for the selectivity).

When I used the device as an rf amplifier in front of my lab receiver, I had to reduce the gain of that receiver by a large amount. That **HEP 590** really has a lot of sock.

Putting the **HEP 590** on 6 Meters

After removing the 40 meter coil and putting in the required values for 6 meters, signals came in right away. Plenty of

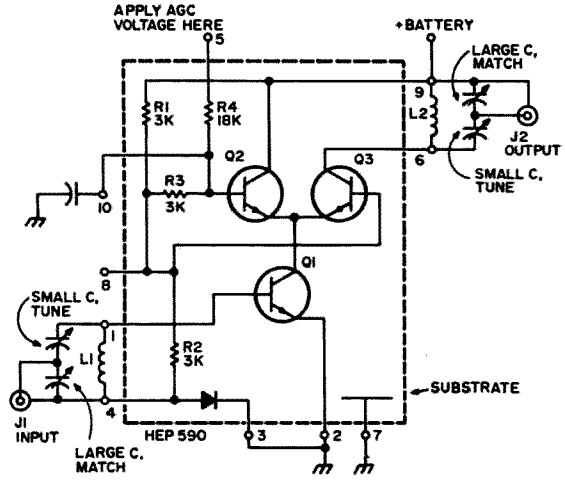

Fig. 4. 6M amplifier built around HEP 590.

stations were heard, and in particular, using a 100 ft wire, Q5 signals were heard that could not even be found on the dial without the 590 preamp. It works! The 6m values for the inductors are as follows: L1 – 4 turns at 8 turns per inch, 9/16 in. diameter; L2 – 5 turns at 4 per inch, 9/16 in. diameter L3 – 4 turns, wound on L2. Figure 4 shows the 6 meter version of the HEP 590 amplifier.

So the Motorola HEP 590 IC linear amplifier works as claimed. It is a relatively easy IC to practice on, with only three active devices inside, and can be built up into a circuit and tested in a day's time.

From working with it so far, I can verify that excellent reduced-size, high-frequency i-f amplifiers for amateurs can be made with it.

The Amperex TAA300

The home of Amperex being not too far away in Rhode Island, I visited down there for half a day and was well rewarded with some new VHF transistors that look swell, and also in meeting some topnotch engineers in the lab.

The TAA300 is a complete af amplifier in one of those little 10-pin cans, and puts out a watt of audio when required – enough to modulate a couple of watts of rf on 6, 2, or 432 – which, along with the exciter section, will take just about all of the dc power of two lantern batteries, rated at 12V and 0.5A.

And it's good for the receiver also. Plug the i-f diode output into it and there's your loudspeaker banging out a watt. Let's take a quick look at one of these.

With ICs, allow for lots of time. Some of this time will be spent in puzzling out three things: the internal circuit, the external circuit, and how to draw one schematic that has both.

I am counting on the TAA-300 to do a lot for use as a 1W af amplifier; but once again, remember that these little gems are not primarily made for experimenters – they're made to be wavesoldered into small radios and TVs by the hundred thousands.

An engineer in a large company can afford to sit down at his desk and spend a week or two figuring how to best put this

New Subscription Rates?

YOU BET

With this issue of 73 we close out our first ten years of publication. In an era of unprecedented inflation we have done well, we think, to keep our subscription rates as low as we have. We started out at 37¢ a copy, went to 40¢ when the newsstands protested the odd figure, then went to 50¢, 75¢, and finally a dollar. Our subscription rate started at $1 a year, and went to $12 for three years back in 1966.

If congress and the administration would try and cut expenses down we suspect that the inflation would stop. As long as they keep the Bureau of Engraving busy three shifts a day printing more money, we can't have anything except inflation, and (as has been proved rather clearly) curbing consumer credit only makes the situation worse by adding a recession to the inflation.

Suffice it to say, we must inch our subscription rates up a little bit more just to stay in one place. The new subscription rates will take effect with the next published issue of 73, thus giving you time to repent over dawdling on sending in your money.

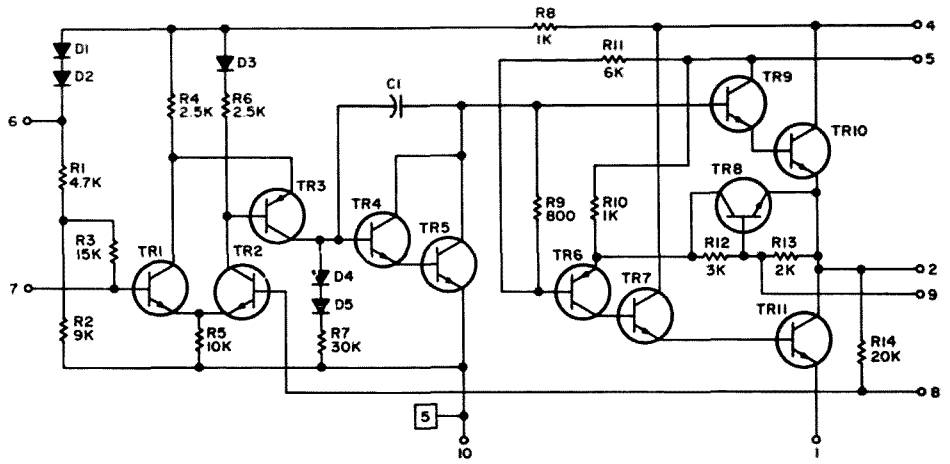

Fig. 5. Amperex TAA300 – a 1W audio amplifier IC.

device into a set because that week can be spread cost-wise over (hopefully) a large number of sets if he does a good job. Can you do this just for one item?

Does the circuit of Fig. 5 look like an audio amplifier? Where's the input and the output? What are those five diodes doing in there? Why 11 transistors just for an af amplifier when the "All-American Five" design will give you mixer, oscillator, i-f, af driver, and af power stage?

Don't think I'm running this thing down, because I intend to use it. I just want you to be prepared for a little "new thinking."

With printed circuitry it has always been my feeling that why should anyone build just one? To learn the printing process involved, yes. For building one circuit, no. Now some of these little 10-pin jobs *are* good for experimenters, and you may also be interested in learning about them for business reasons, too – or for size, although to really cut down in size calls for some pretty expensive external components. Look at Fig. 6, the external circuit. There is a .64 μF capacitor on pin 6, 400 μF from pin 2 to pin 5, a 25 μF capacitor on pin 8, and 47 μF from pin 2 to ground. With "ordinary" size electrolytics three of these values are each four times the size of the device itself, but I expect with voice frequencies some of these can be cut down a bit.

Then there are a few application notes to think about, like the stability question, and a few others, but they are not bad.

All worth-while things take time, and this is one of them. Be advised, and allow yourself time enough to study it out before you pick up that little soldering iron.

Amperex TAD100

Ambitious, knowledgeable, hardworking people have looked at the several-million-per-year market for just plain old radios (new ones, of course) and thought about making ICs for them. And they made some. I have worked with one of them, the Amperex TAD100, and here is the story as I found it.

There are a dozen or so transistors in the little plastic box only 3/4 in. long, as you can see in Fig. 7, the internal circuitry of this one. These transistors are pretty close together in there – much too close for an amateur experimental unit, as you will see.

The manufacturer, ambitious as he was, did produce large numbers of excellent and very tiny receivers with this IC. It has a mixer, oscillator, i-f, detector, and an af amplifier – but no power stages. Almost everything you might need, except you have to add a few things on the outside, of course, as shown in Fig. 8.

There are some good ideas incorporated into this baby – like using two transistors for the mixer. So are three for one i-f stage. I don't particularly go for the four transistors in the af stage, without even the power output unit yet, but it does work.

What doesn't go for the amateur experimenter is the fantastic proximity of the input, the mixer, the oscillator, the i-f and

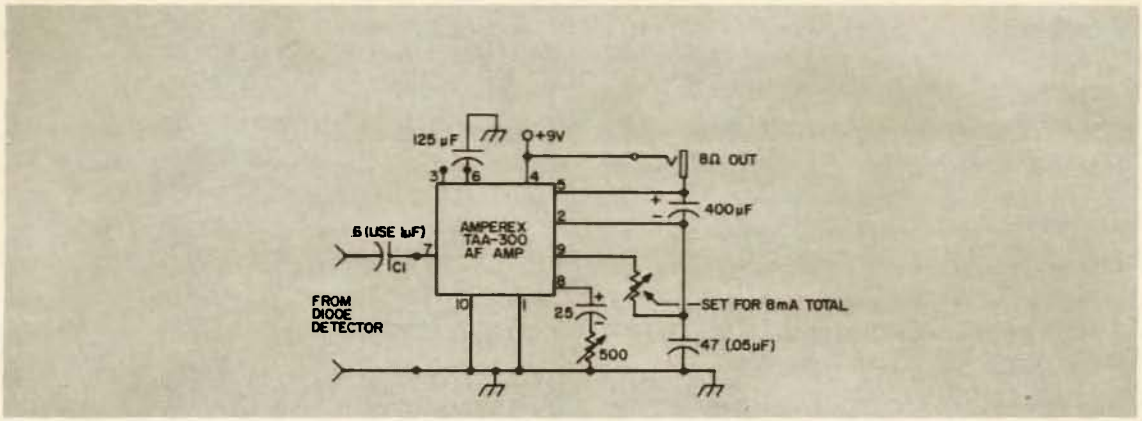

Fig. 6. External connections required to get the TAA300 operating as a complete amplifier.

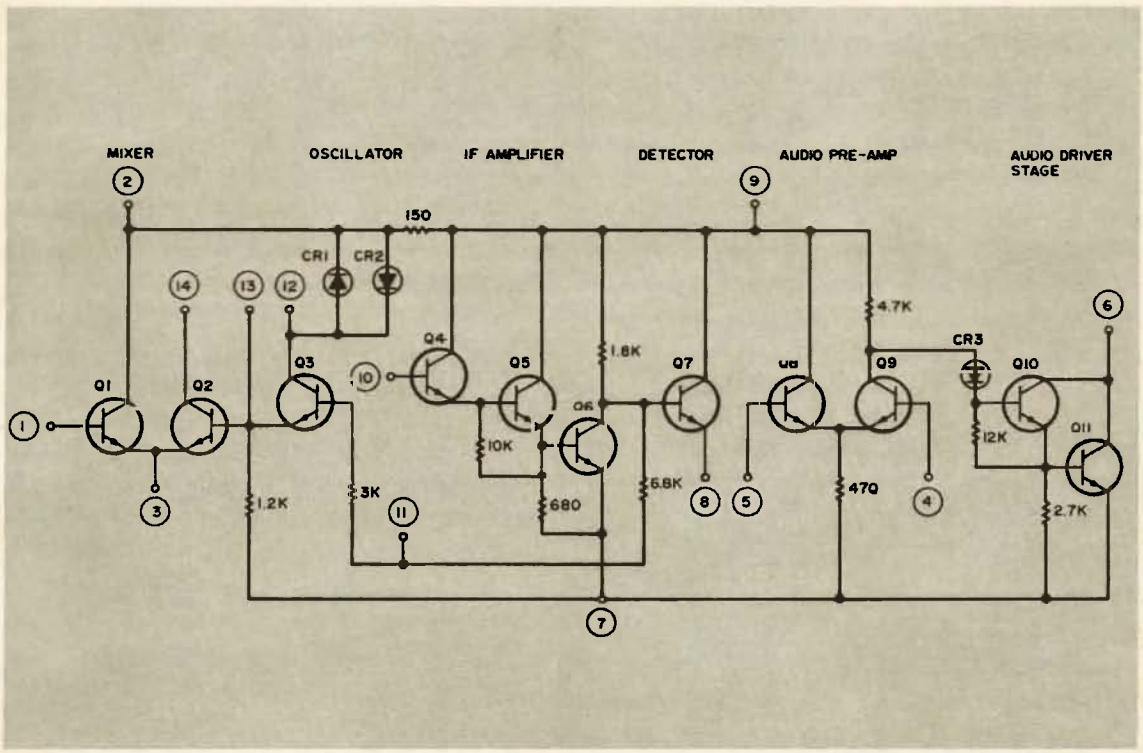

Fig. 7. Amperex TAD100 is a complete broadcast receiver in one tiny package.

the af – all in there together on that one tiny chip. Just too, too close for me. When everything is running right with all the precautions advised and an exact copy of the original printed board is made up and all the components are in exactly proper places, it does work as a BC set.

One of the precautions listed: "The oscillator must be limited to 100 mV; otherwise it will get into the i-f and the af." It did! I worked 10 days on this particular IC and to make a long story short, the mixer and the i-f ran okay at times (and at times not), but when the internal local oscillator was used, I kept running into trouble.

Bear in mind, such an IC does work fine for mass production of BC sets. It's just that for an amateur experimenter as a single unit, there is too much feedback involved. Also, the oscillator is strictly limited to the BC band service, which

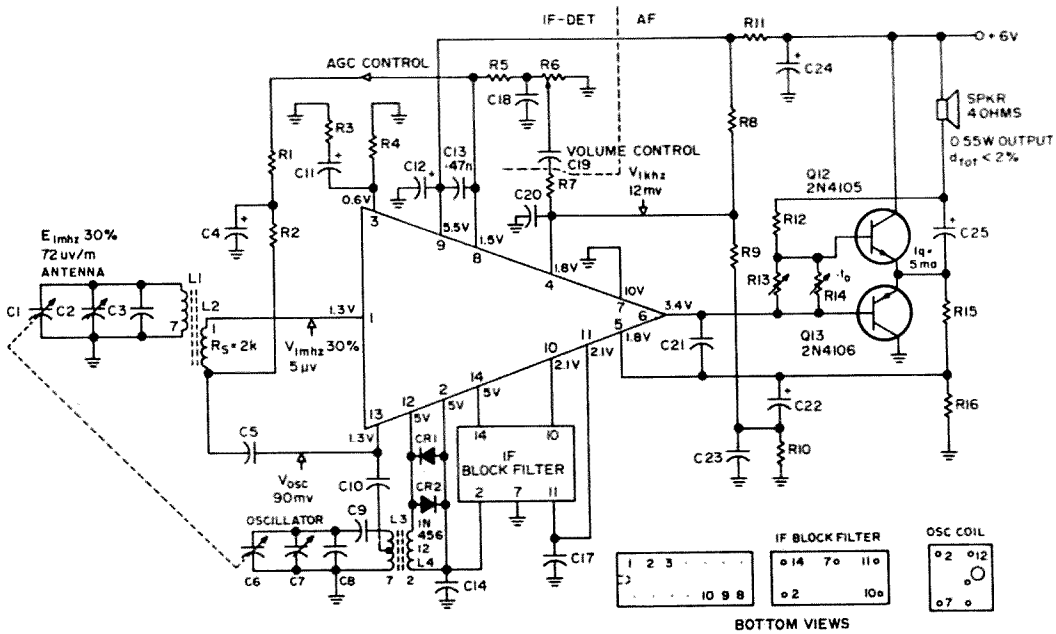

Fig. 8. External circuitry, B.C.—I.C.

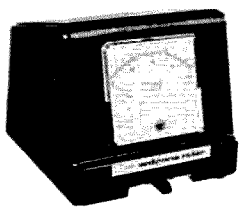

precludes using it as an amateur converter. The people handling this unit are excellent engineers and have some other *very* good devices; and they are still working with newer and better devices for a complete set (including an FM job!), so we will almost certainly see them again soon.

(Cont. from page 10)

is irrelevant. I did notice that most of the fellows that managed to work through to me were interested in a New Hampshire contact or else wanted to just say that they enjoyed the magazine. No traffic for the news pages ever developed.

I'll try and get on around 14.210 or so at 2100 and 0200–0300 whenever I can. If you have news items please just mail them in and let's forget that General section of 20 meters.

News Pages

If you are involved or get word of anything that you think would be of value to the 73 newspages please take it upon yourself to act as a reporter and get the news in to us. The last minute for each month is the 20th.

The news pages not only are of considerable value to our regular readers, but we go to the trouble and expense each month of reprinting the first two pages and sending them to every congressman in Washington. Thus your news stories can do a great deal towards creating a favorable climate for our hobby in Washington.

In addition to the news story having your byline, we will also send you a PRESS pass which can help you get into restricted places for future news stories.

In addition to news which is of national or international interest we also would like to have news of activities on the various amateur bands . . . particularly interesting nets . . . unusual contacts . . . DX stations of note . . . VHF band openings . . . contest announcements . . . special awards . . . etc. These announcements won't warrant a press card and byline, but they will help to make amateur radio more fun for all of us.

Your Vote Counts

Half of the sixteen ARRL directors are up for reelection each year. When those of you who have not dropped out of the League cast your vote this fall you might keep in mind that little is to be gained from keeping the same old faces in office. A reading of the minutes of the last board meeting will tell you the story. . . most of them are sales reps coming to you from headquarters rather than your representatives running your club.

More Phone Bands?

The September issue of QST carries an article on why the ARRL directors decided against expanding the U.S. phone bands. The article is interesting, but completely out of touch with the realities of 1970, expressing the leftover concepts of twenty years ago.

The main theme is that if we expand our phone bands, phone operators in the rest of the world will move into the CW bands to get away from us. Back in the AM days this would have been so. It is unfortunate that so few directors and HQ personnel are active amateurs; otherwise, they would certainly have realized how completely out of date the arguments were.

Few DX contacts are made cross-band these days compared to the old AM days. Twenty years ago it was unusual to work a DX station operating inside the U.S. phone band. Today it is extremely unusual to work one outside our band, with the exception of a few DXpeditioners who have curious reasons of their own for split-frequency operating. There are times when it is better for a rare DX station to work split, but the need for this is unusual. There seems to be little need for a "DX" portion of the band today for phone.

While operating from JY1 I tried operating above and below 14200 and I found vastly more DX activity above 14200 than below. The lack of U.S. phone stations below 14200 has encouraged commercial occupation of these frequencies and few of them are free of this sort of interference, and thus few are of much use to anyone anywhere. If this band were opened to U.S. phones I believe that the periodic assaults of QRM from the U.S. would drive a great many of these interlopers to clearer channels, thus benefiting amateurs everywhere.

It is unfortunate that the ARRL directors are so inactive that they are not aware of conditions as they are in 1970 and thus were talked into completely giving up the weak try they made to get HQ to push for more phone frequencies.

If you think I am exaggerating or coloring this then please take the time to read the Walker article in QST and the board minutes. Ugh.

. . . Wayne ■

WHEN IT COMES TO ANTENNA SYSTEMS... IS YOORS

a space problem? a budget problem? an applications problem? an installation problem? or simply a problem of where to buy?

Your one-stop solution is ANTENNAS, INC.
Exclusively specialists in radiating systems, complete systems or any component part.
Arrays—complete or in kit form, quads, yagis, dipole assemblies, verticals—fixed or mobile, towers, masts, rotors, guy and control cable, transmission line, coax relays and switches, connectors and adaptors, test gear, technical publications, corrosion resistant hardware, corrosion proofing chemicals, insulators, installation and wiring hardware, aluminum tubing and plate, wire, and much, much more.
If your requirements are for a complete system, major components, or the smallest yet important piece of hardware—

Our prices and deliveries are hard to beat . . . anywhere.

ANTENNAS, INC. Dept. B, 512 McDonald Road Leavenworth, Kansas 66048.

ANTENNAS, INC. can be your one-stop, single-source. Write today for our catalog, $2.00, refundable, first order.

PRACTICAL IC REGULATOR CIRCUITS FOR HAMS

Don Nelson WB2EGZ
9 Green Ridge Road
Ashland NJ 08034

The experimenter has broad horizons with the many low-cost ICs and semiconductors available today. While many of the ICs have been designed for a specific service, such as an audio amplifier or a logic switch, there are types which contain several transistors to be used in almost any application. The RCA CA3018 exemplifies the second category. Let's examine the device as an introduction to integrated circuitry.

Four silicon transistors are formed on a common monolithic substrate within the CA3018. Two of these transistors are interconnected by having the emitter of one tied to the base of the other. Either of these transistors may be used separately since an external lead connects to the emitter-base link. The intent of the interconnection is to use the transistors in a Darlington circuit. The other two transistors are isolated as shown in Fig. 1. Notice the substrate is important enough to have its own lead. In this IC, as in most others, there is diode action between the substrate and some elements of the circuit. You can see this characteristic using an ohmmeter between the collectors and the

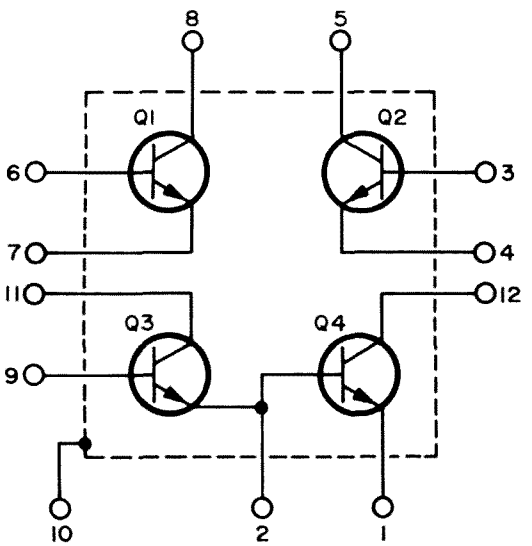

Fig. 1. Schematic diagram of RCA CA3018. Numbers refer to pins of IC.

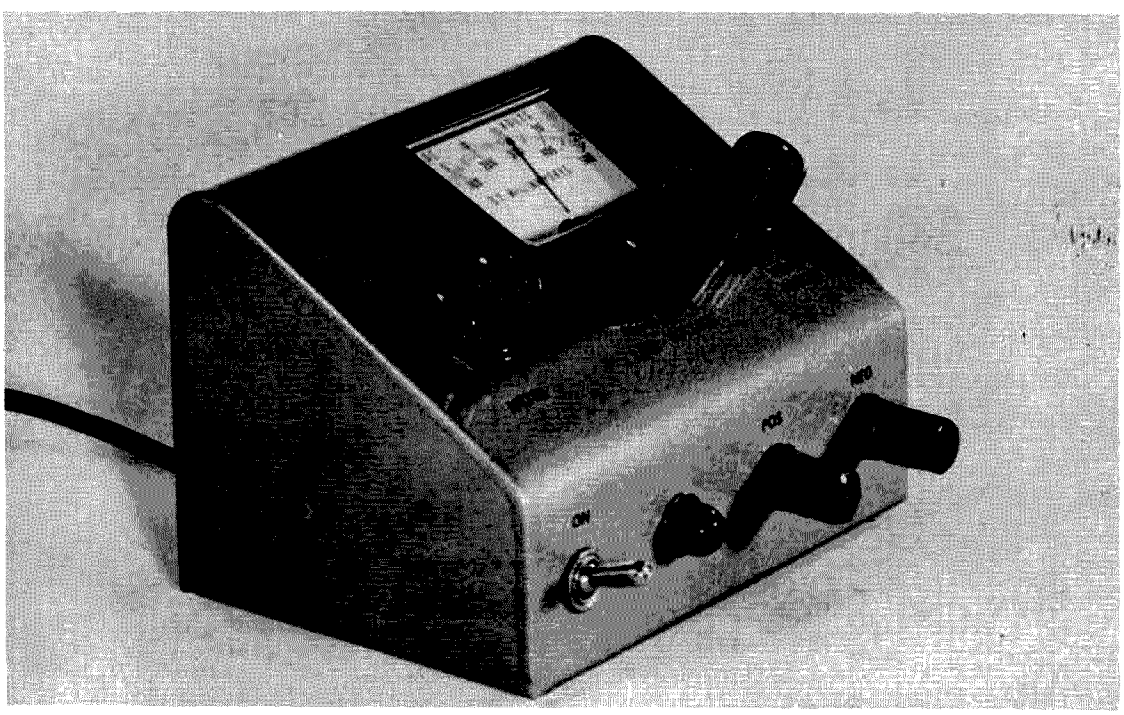
substrate. These diodes are reverse-biased by connecting the substrate to the most negative point in the circuit, thus isolating the transistors. If the substrate is not connected in such a fashion, you may not get transistor action from the circuit.

The transistors in the CA3018 are useful from dc to 120 MHz. One of the big advantages of integrated circuitry is the matched characteristics of the transistors within. Gain, for example, is matched better than 10% and the base–emitter voltage match is better than 2 mV over a wide temperature range. Because of these characteristics, this and other integrated circuits are excellent for temperature-compensated circuitry.



Another plus for most ICs is the excellent low-frequency noise figure. Transistors in the CA3018 array boast 3.2 dB of noise at 1 kHz. At 100 MHz, the noise figure is typically 7 dB, so this device is favored for operation below VHF.

Learning to use the best characteristics of a device and learning to design around its limitations are good engineering practices. I once heard a ham brag, "The 4X150 is a great little tube – mine is dripping solder from the radiator, but my power output hasn't dropped." Well, those good old days are gone when you use semiconductors – so learn what the ratings are all about. Maximum and minimum values for the CA3018, which must be observed, are listed in Table I.

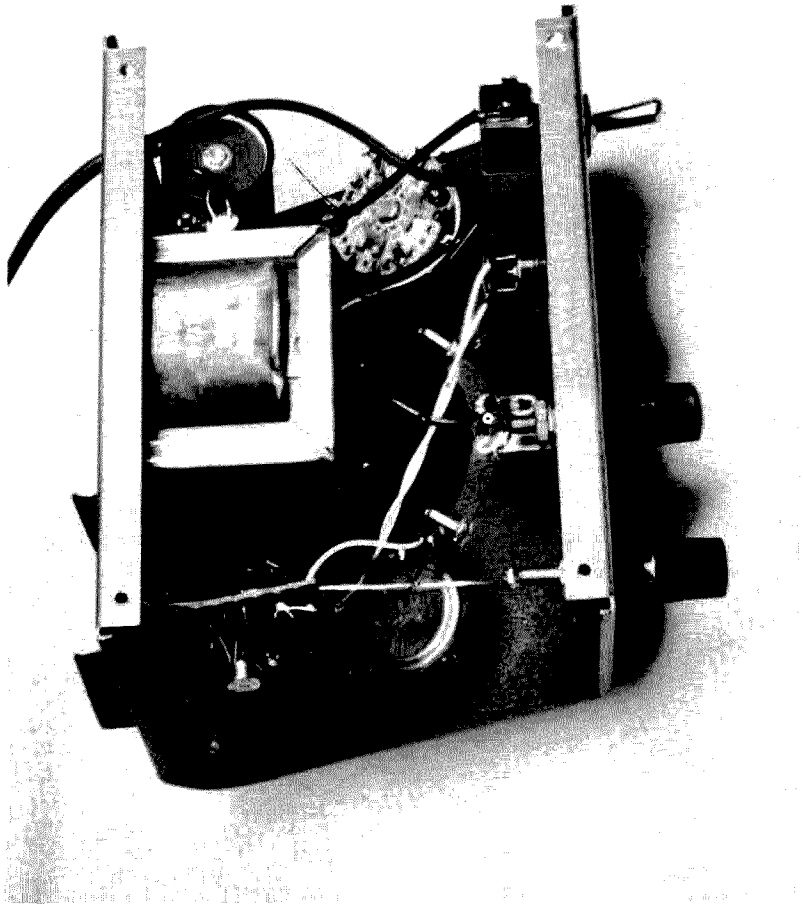


Table I. IC Parametric Limitations at 77°F.

Parameter	CA3018	CA3018A
Maximum power dissipation:		
any single transistor	300 mW	300 mW
total package	450 mW	450 mW
Derate 5 mW/°C for TA >85°C		
Maximum collector-to-emitter voltage	15V	15V
Maximum collector-to-base voltage	20V	30V
Maximum collector-to-substrate voltage	20V	40V
Maximum emitter-to-base voltage	5V	5V
Maximum collector current	50 mA	50 mA

Those readers who are familiar with transistors will find only two new ratings; a total-package power rating, and a collector-to-substrate voltage rating. The first is a limit for the sum of the power dissipation of the individual transistors. For example, if one transistor operates at the 300 mW level, the average power of the remaining

Exterior view of the 500 mA power supply. The case used is a Bud CMA 1930.

Placement of parts is only critical with respect to squeezing everything into the box. The 2N5295 transistor is outside the rear apron and insulated from the main chassis. A piece of copper 2-1/2 x 2 x 1/32 in. forms a heat-sink for the power transistor.

three may not exceed 50 mW each (300 + 3 x 50 = 450). The second new rating refers to the breakdown voltage of the collector-to-substrate diodes. These diodes are always reverse-biased because the substrate has been connected to the most negative part of the circuit. It is easy to determine the exact voltage in a circuit because the collectors are frequently at the most positive voltage.

Many ICs have low breakdown voltage ratings, which can be a serious disadvantage. In some cases, you may be able to design around the problem. Another problem at the experimenter's level is the fact that if one transistor is destroyed, the whole IC has to be replaced. This disadvantage is somewhat offset by the low $1.62 cost of the CA3018, but it is hard to rationalize soldering 24 leads for each mishap. A discrete transistor could be used in a crisis with the CA3018. Better yet, use a socket for breadboarding.

Applications

The CA3018 is a natural choice for a power supply regulator amplifier. Such an application, I feel, is also interesting for analysis. In Fig. 2, I have drawn a very basic regulated power supply using three of the transistors. Let's examine its characteristics from the ratings of the IC.

Nearly all the current to a load will flow through Q4 (pins 12 and 1); therefore, we are limited to 50 mA, which is the maximum collector current of any single transistor. If you think about it, this is all the current required by many circuits. The power supply could service almost any circuit now operated on small 9V batteries. An FM portable receiver draws peaks of less than 20 mA; AM radios draw even less.

The second rating to consider is the collector-to-emitter voltage. The greatest permissible value is 10.5V, which is well under the 15V rating of the transistor. The collector–base breakdown voltage is not

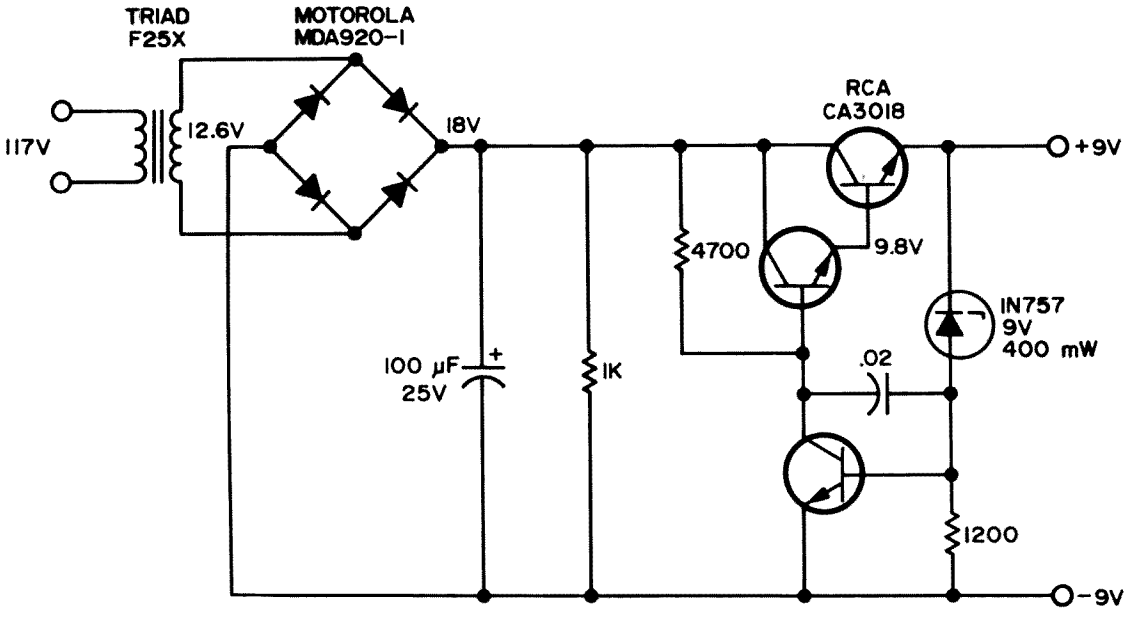

Fig. 2. Regulated 9V 30 mA power supply using CA3018.

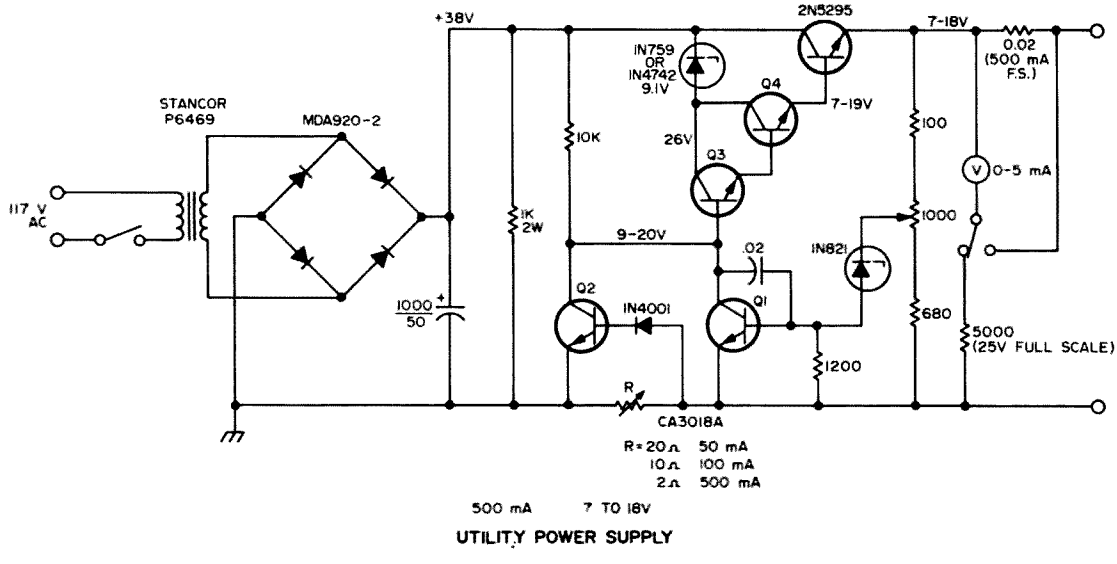
exceeded and the emitter–base junction is never reversed-biased, so the design is clean in those respects. Don't forget the collector-to-substrate rating. In this case, the maximum voltage seen is 18V: okay for this circuit, but not for the next one.

When considering the power rating, it is safe to assume we will not exceed 85°C (no derating necessary), and the power dissipation of Q4 will be much greater than the total power of Q1 and Q3. At 50 mA of current, the power (P=IE) would be .050 (18–9)=0.450W, which is high for a single transistor. A reduction in output current or lowering the input voltage on pin 12 is necessary to operate within ratings. In any case, it would be wise to heatsink the IC for this circuit. You may expect it to get hot above 30 mA.

The shortcomings of the CA3018 become apparent as we attempt to design a more versatile supply such as the one in Fig. 3. A 2N5295 power transistor was added to the basic circuitry in order to



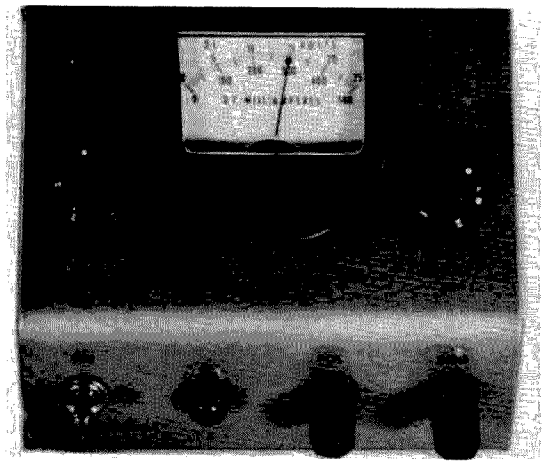


Fig. 3. "Utility" power supply with 7–18V output. Resistor R determined by current requirements: 20Ω–50 mA; 10Ω–100 mA; 2Ω–500 mA.

The completed 500 mA regulated low-voltage power supply.

operate to supply to 18V and 500 mA. Other changes include the use of a temperature-compensated zener diode, variable voltage output, and current limiting by use of the fourth transistor on the IC. Incidentally, you might just want to build a power supply like this if you are newly acquainted with semiconductors.

The 2N5295 will handle 500 mA and higher voltage with ease. If we assume the beta of that transistor is 50 at full load, the base drive required would be 500/50, or 10 mA. That is no problem for Q4 of the CA3018. On the other hand, it soon becomes apparent that we need higher than 20V breakkdown. Some relief is obtained by using the CA3018A, but not quite enough to handle the collector–emitter voltage drop across the Darlington pair. By using a zener diode between the high-voltage point and pins 11 and 12 of the IC, the collector-to-emitter voltage requirements are reduced, as is the collector-to-substrate voltage.

It is not necessary to use a temperature-compensated zener here. Collector-to-emitter voltages are the only ones above ratings now. Three CA3018s tested had collector-to-emitter breakdown voltage ratings in excess of 23V; however, this is a weak point in the design.

Power requirements are lower with the addition of the 2N5295. The maximum power through Q4 is 23V x 0.010A= 0.230W, enough less than the maximum rating that no heatsink is necessary.

A word about the operation of the current limiter is in order for any prospective builder. Transistor Q2 is normally turned off until an overload occurs. At this time, the voltage drop across **R** is enough to turn on the 1N4001 and the emitter–base junction of Q2. As the transistor is turned on, its collector is pulled toward ground, thus turning off Q3, Q4, and the 2N5295. As soon as the overload is removed, the supply recovers to its former voltage. This limiter may be made variable for limiting at lower currents. Approximate limiting values are shown in the schematic. Under extreme current limiting conditions, the collector-to-base voltage of Q3 and Q4 will approach 26V. This is acceptable for the CA3018A.

While the CA3018 is not truly a circuit, it provides an interesting introduction to the technology and characteristics of integrated circuitry. Its versatility invites experimentation. For those who would like to duplicate the regulated power supply shown in the photos, I include a full-size

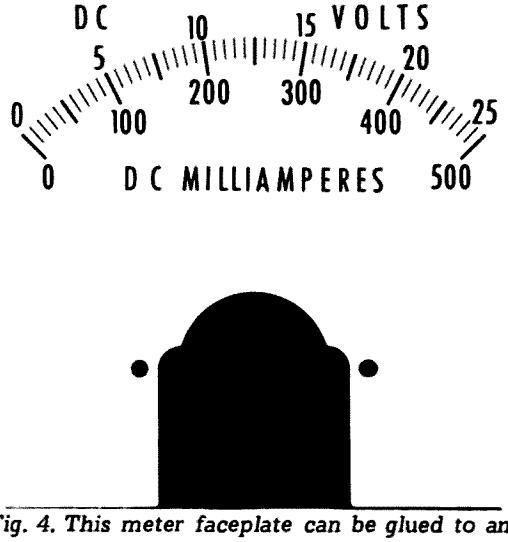

Fig. 4. This meter faceplate can be glued to any appropriate sized meter with a 5 mA full-scale rating.

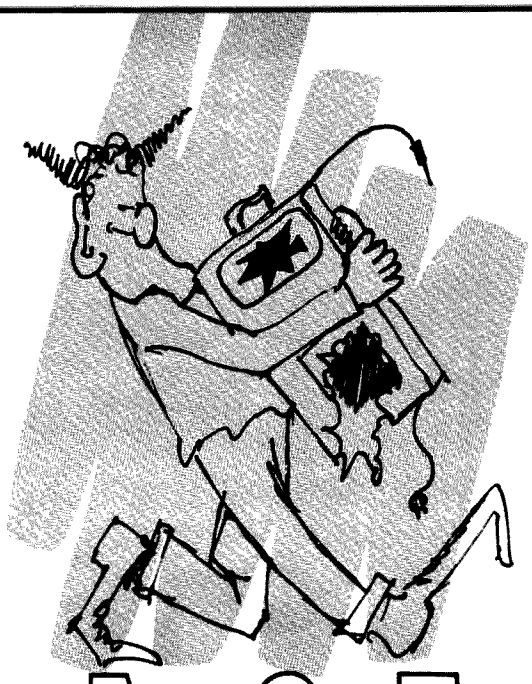

copy of my meter panel as Fig. 4. This can be copies or cut from the magazine and glued to the face of an appropriate 0–5 mA meter.

Reference:

Several other interesting circuits for the CA3018 are discussed in the RCA integrated circuits manual, where complete ratings and typical characteristics are listed.

CAMOUFLAGE

Most *73* articles tell, but this one asks. The usual how-to piece gives counsel from one ham to many on what need be done to solve a stated problem, but this one reverses the process.

Because a quarter-million heads are better than one, advice is sought from the collective conscience of hamdom for the immediate benefit of one amateur – namely me.

In exchange for such desperately needed aid, I am prepared to provide similar-type advice in the same field acquired the hard way, through personal experience involving cut-and-try methods refined in the crucible of actual domestic confrontation.

Camouflage!

A recent proof of this pudding in my own background went this way:

Like this:

If you've bought a new piece of gear you're unable or unwilling to explain to your XYL, equipment costs being what they are and "holdout" money piling up in your wallet's secret compartment the way it does, here's the formula to follow:

Stopping off at a hardware store on my way home from Happy Harry's Ham Headquarters with a shiny new Drake R-4A under my arm in its shipping box, I bought the things a fellow needs under such circumstances.

The clerk said, pointing to my burden, "What ya got in the carton there, Charlie?"

Knowing him to be a big-mouth type who sometimes waits on my wife, I told him, "Frabbersnatches for my flibbergist, and the danged things leak. You got transparent masking tape and some window putty?"

He did have, so I bought some, added a can of red Rustoleum, and retired to my private – if shabby – office.

After sending my secretary (a nosy type who thinks more of my wife than she does of me) across town to get a signature on an obsolete deed from a guy I knew to be vacationing in Guatamala, I went to work.

Inside my sanctorum with the doors locked and my phone off the hook, I taped, painted and puttied.

In half an hour the new Drake looked like a World War II field telephone junction box nine years out in the rain. Switching the shiny black knobs for some assorted beat-up brown and gray ones I keep in my desk for just such purposes completed the transition.

I then carefully shredded the new shipping carton and the bill of sale into little pieces, flushed them down the office dooley, and stuck the Drake into a battered cardboard box the janitor used for

his supplies.

Then I went home with it.

The XYL met me at the door, where I avoided her glassy eye by staring at her messy hairdo. "Been to the beauty shop today, Honey?" I asked in hearty greeting.

She mumbled something unintelligible, turned up her nose at the Drake, and uttered those welcome words.

"I wish you'd quit hauling that junk home to fix for your rotten friends," quoth she.

See how easy it is?

Of course, after a few weeks the paint-streak rust spots and the putty scars can be wiped off the gear, a little at a time, the protecting tape stripped away, and the original knobs replaced one by one.

If the transitional work is done gradually, your resident enemy won't notice that the beat-up box has been transformed into a thing of beauty.

On the other hand, if she or the spies she has mothered are the observant type, you can leave the camouflage in place until you're ready to trade it off for a new goody.

Either way, scarred up or cleaned off, the receiver's utility as a signal-catcher won't be affected by its exterior appearance, though your well-being may be.

In the same way, I've quietly acquired through the camouflage system a 24-hour digital readout station clock, swr bridge, coax switch, electronic bug, VTVM, scope, mobile rig, and beam rotator, all on hold-out money and all without attracting my wife's attention.

I recommend the system unequivocally.

But now comes the problem, and here's where I need help and advice.

So far, my camouflage activities have been relatively minor-league, not really preparing me for the major-league ordeal ahead, the crucial crisis that separates the men from the boys.

Please, you out there, rescue me with some counsel: How do I smuggle up in my back yard (without the XYL noticing it) the new 50 ft mast and tribander hidden in the basement of my office building?

THE PHASE-LOCKED LOOP COMES OF AGE

It's been a little more than 13 years now since the idea of "synchronous detection" entered the ham radio world – and the odds are, unless you're a dedicated VHF and DSB (yes, we said *D*SB) nut like I am, you still haven't heard very much about it.

Not that some of us haven't done our part. The initial publication of an article of the subject back in 1957 (three years before *73's* birth) was accomplished under Wayne Green's guiding hand in CQ Magazine, and the next synchronous-detection bombshell (conservatively titled *50 dB Under the Noise – A Breakthrough*) saw the light of day in the short-lived pages of 6-Up, *73*'s subsidiary VHF magazine of the mid-60s.

But all the way through, the synchronous detection idea has had a tough obstacle to battle: While it does give all the performance claimed for it, it requires several times as many components as does a conventional detection circuit. The 1957 version used eight double-section tubes to give 16 stages; the 1964 edition (actually a completely separate implementation of the same basic idea but giving other features) was solid-state and required 24 transistors.

Quite obviously, this is a larger stage count than that of many complete receiver designs. So long as so many devices were necessary, the synchronous-detection idea just couldn't make it in the face of its much simpler competition.

But all that was changed in the last year when a major manufacturer of integrated circuits put together a single-chip circuit which does just about everything required for the synchronous detector, in a single standard-sized 16-lead dual-inline IC package. Although it contains approximately 50 transistors, the whole thing takes only

about 10 mA from an 18V supply, and is hardly as large as a commemorative postage stamp.

And to top it off, the price of the device is surprisingly low, considering what you get. There are several different versions with different features, but the least costly of them is still a complete FM receiver which accepts a minimum 300 μV signal (across 3 kΩ) at any frequency from 100 Hz up to 60 MHz or so, with any deviation up to +20% of center frequency, and produces 60 mV of audio output across 8 kΩ. This one costs $30 in single-lot quantities, according to the most recent price list, but that's all you need for a complete receiver within its frequency range and sensitivity.

On top of this, remember that these are current prices, and the unit is not yet in wide use. If it catches on as it apparently should, the cost is bound to come down. Remember when the CK-722 transistor sold for $7.50 each? And now they're down to 4 for $1 from the mail-order houses?

What Is Synchronous Detection?

The words "synchronous detection" have been applied to many different detection schemes, but all of them share the idea of using a stable local oscillator to mix with the incoming signal, and developing an error signal should the local oscillator get off frequency. You might call it a sort of superhet receiver, with automatic frequency control and a zero-frequency i-f, if that brings any reasonable picture to mind.

The most common type of synchronous reception currently used (yes, it *is* being used – by radio astronomers, space communications systems, long-range radar, and any place else that the ultimate in radio communications is required, thus justifying the complexity and cost of the older approaches) involves a "phase-locked loop."

The phase-locked loop includes a phase detector, a low-pass filter, and a voltage-controlled oscillator. The phase detector is a circuit which accepts two different rf input signals, and produces a dc-to-audio output signal which reflects the phase differences between the two inputs. That

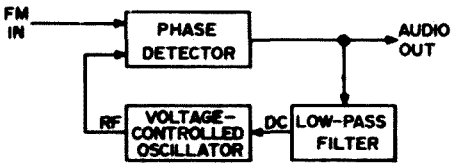

Fig. 1. Basic phase-locked loop or synchronous detection hookup for FM reception uses voltage-controlled oscillator in a servo loop. Output of VCO is continually compared with input signal in phase detector, which produces an output consisting of dc voltage which varies as input frequency changes (which amounts to superimposed audio). Low-pass filter wipes off audio and dc goes to VCO to keep it locked to input signal. Unfiltered error voltage from phase detector is the audio modulation of the signal.

is, so long as both inputs are in the same phase relation to each other (usually 90 degrees), output of the phase detector is zero. If the phase of input A begins to lag, output goes positive, and if input A begins to lead the other, output goes negative.

If we could keep an oscillator absolutely stable on the center frequency of an FM transmission, we could feed its output to one input of the phase detector, and feed the other input with the FM signal. The output would then faithfully reproduce the phase differences, which would reproduce the audio signal envelope.

If we could keep an oscillator absolutely stable on the center frequency of an FM transmission, we could feed its output to one input of the phase detector, and feed the other input with the FM signal. The output would then faithfully reproduce the phase differences, which would reproduce the audio signal envelope.

And that's the way the phase-locked loop (abbreviated PLL) works. The phase-detector output is filtered to remove any audio and retain only the dc component, which is a measure of the drift in the local oscillator, and then applied as an "error signal" to the local oscillator to keep it locked in phase with the incoming FM signal.

The filter keeps the voltage-controlled oscillator (VCO) from following the audio, so we pick the audio off ahead of the filter, and we have an FM detector (Fig. 1).

For AM reception, we do things a little differently. We lock the VCO to the incoming signal, just as before, but we add things.

It works out to be something very much like SSB reception; many years ago QST pushed something they called "exalted carrier reception," which involved using two i-f strips, one extremely sharp to pick out the carrier from between the sidebands for high-gain amplification, and the other to accept the sidebands.

Our phase-locked AM reception is just about the same, except that we generate a new carrier in the VCO which is phase-locked to the incoming carrier, and use that to demodulate the sidebands. The demodulation is accomplished in a "multiplier circuit" which is more familiar to most of us as a "product detector" or "mixer." Another low-pass filter shaves off the original input-frequency signal, the VCO signal, and the *sum* frequency from the product detector's output, leaving us the *difference* frequency, which turns out to be the audio we wanted to recover.

Note that this arrangement (Fig. 2) cannot demodulate an SSB signal since

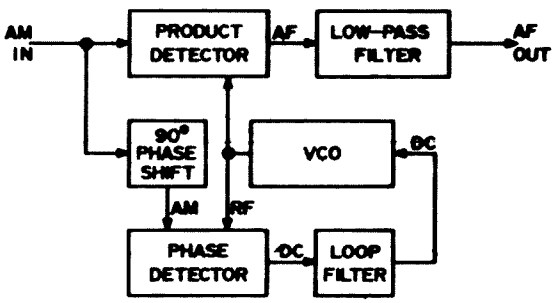

Fig. 2. AM detector using phase-locked loop is a bit more complex. Incoming AM is shifted 90 degrees in phase and VCO is then locked to it. VCO output is used as bfo input to product detector, to recover audio. Low-pass filter in audio signal path removes intermediate, VCO, and sum frequencies, leaving only the difference-frequency output of the product detector.

there is no carrier present for the phase-lock loop to lock onto. In such a case, it would attempt to lock on the strongest sideband component present with notably less than satisfactory results.

Barker & Williamson

UNIVERSAL HYBRID

PHONE PATCH

MODELS 3001 and 3002

- Connects receiver and transmitter to phone line for remote voice operation!
- Connect Tape Recorder for recording and playback!
- Built in compreamp speech preamplifier/limiters!
- Mounts vertical or horizontal!

Model 3001 identical to Model 3002, but without built-in compreamp

This B & W Universal Hybrid Phone Patch is another of the fine Waters Amateur Radio Communication Products now manufactured and marketed by Barker and Williamson.

DIVISION OF SUNSHINE MINING CO.
CANAL ST., BRISTOL, PA. 19007

See your local dealer or write dept. D for descriptive literature.

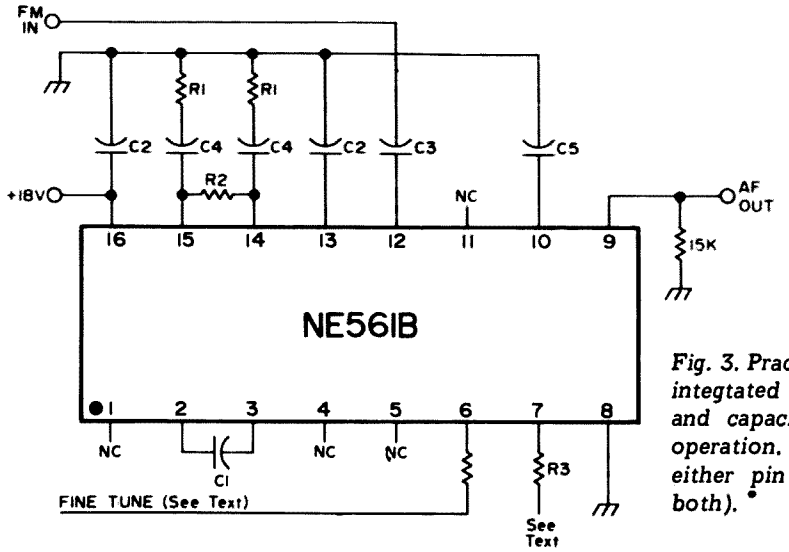

Fig. 3. Practical versions of PLL using integtated circuit with external resistors and capacitors to select frequency of operation. FM input may be applied to either pin 12 or 13 (or push-pull to both).

The 1957 circuit, by Dr. John Costas W2CRR and G. K. Webb WØAHM/2 (both with General Electric in Syracuse, N. Y. at that time), overcame the problem by deriving the control voltage for phase-locking from the sidebands rather than from the carrier. Unfortunately, their circuit has not yet been implemented on an integrated-circuit chip so far as we have been able to learn and so we must wait a bit longer for that happy time.

Right now, though, we can build an FM receiver with excellent performance which will also be able to detect conventional AM, for a small fraction of the cost of conventional receiver circuits.

How Can We Use Phase-Locked Loops?

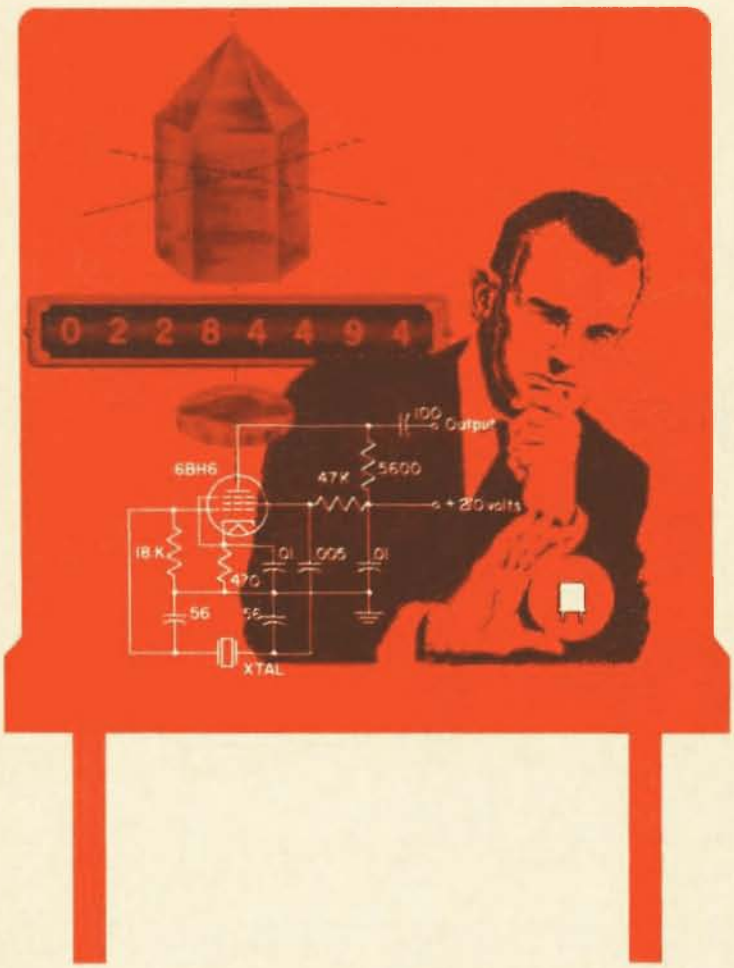
No new component, no matter how interesting it may be, is of much good to many of us unless we can put it to use. The logical question at this point, then, is "How can we use phase-locked loops?"

In the initial report describing the IC phase-locked loop, Dr. Alan B. Grebene listed nine electronic circuit functions for which he felt it was well suited:

1 – FM i-f strip and demodulator for commercial FM receivers.
2 – Commercial TV sound i-f and demodulator.
3 – Tuned AM detector.
4 – Self-contained SCA (storecast music) receiver.
5 – FM/multiplex telemetry receiver.
6 – Signal conditioner and limiter.
7 – Frequency-shift telegraph receiver.
8 – Frequency selective multiplier and divider.
9 – High-linearity FM detector for wide-deviation FM.

To his list, we can add several more directed specifically at amateur use:

10 – VHF FM mobile receiver for compact cars.
11 – VHF FM handheld receiver.
12 – Frequency synthesis for high-accuracy VHF FM transceivers (*Boelke, 73*, Feb. 1970).



Some of Dr. Grebene's suggested applications are outside our scope, such as the telementry receiver, signal conditioner, and TV sound demodulator. Several of the others telescope into a single application when signal frequencies are ignored – that of a versatile FM receiver. So let's see how to use the PLL (phase-locked loop) IC as an FM receiver, as an AM receiver, as a frequency multiplier, and as a FSK RTTY converter.

Let's emphasize that the circuits which follow are taken from the manufacturer's published applications notes and literature; we have not breadboarded any of them and so cannot guarantee results (but let us know if you have troubles with any of them).

FM Receiver

FM reception is simple with the IC PLL; that's the job it appears to have been invented to do in the first place. When it's running "locked" to a signal, the average dc level of the phase-detector output is

There Is a Difference In Quartz Crystals

Space age communication equipment demands a crystal that meets all standards of technical advancement. Crystals that were acceptable some years ago do not meet present day specifications. As a general rule, your crystal must be selected from the best quartz . . . (no throw off cuts). Tight tolerances demand selected angles of cut. The x-ray is important in making this selection. The crystal should be preaged with stress cycling. It should be checked for frequency change vs temperature change. It must be checked for optimum spurious response. It should be calibrated to frequency with the correct oscillator. International Crystals are manufactured to meet today's high accuracy requirements. That's why **we guarantee all** International crystals against defective materials and workmanship for an unlimited time when used in equipment for which they were specifically made.

directly proportional to the frequency of the input signal. As the input frequency shifts with modulation, it's this dc output that changes and causes the VCO to shift its frequency to remain locked on the input signal.

The only problem to face in building an FM receiver with the IC PLL is that of setting it up for the proper input signal frequency. The VCO center frequency is set by an external timing capacitor, and by varying the value of this capacitor we can work at any frequency from 100 Hz up to a guaranteed 15 MHz, with typical units operating to 30 MHz and operation as high as 60 MHz possible by a trick we'll pass on a little later.

The connections necessary, as well as the external components required, are shown in Fig. 3. Capacitor C1 is for timing; its value in picofarads for frequencies in the range from 100 Hz to 30 MHz is shown in the left-hand graph of Fig. 4. This capacitor provides a "coarse" adjustment of frequency which can be trimmed by variation of capacitor value. For "fine" frequency adjustment, current must be injected into pin 6 through a series resistor from the power supply; the right-hand graph of Fig. 4 shows the percentage of frequency change achieved for various values of current injection.

CHAMPAIGN, ILL. 61820

The other capacitors shown in Fig. 3 are bypass capacitors (C2), coupling capacitors (C3), and low-pass filter capacitors (C4). Their values are dependent to some degree upon the center frequency chosen. The deemphasis capacitor (C5) should be larger than 200 pF for commercial FM reception;

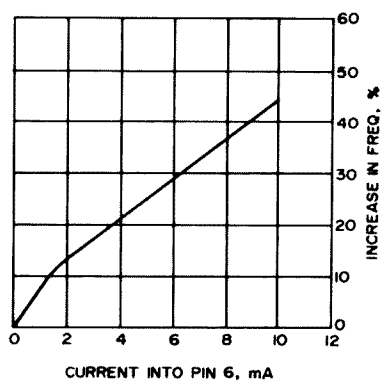

Fig. 4. These two graphs show how operating frequency of VCO in IC PLL is set. Graph at left shows approximate center frequency as value of C1 is changed through the range from 1 μF to 10 pF. This is coarse frequency setting, determining lowest operating frequency. Graph at right shows how frequency increases as current is fed into pin 6; approximately 45% increase in frequency can be attained by this means. This provides "fine tuning" control.

its value is subject to experiment for communications purposes.

Resistors R1 together with capacitors C4 form the low-pass filter; it's fed by an internal impedance of 6 kΩ at pin 14 or 15. Typical values for R1 and C4 are 50Ω and 1100 pF.

The locking threshold of the circuit may be controlled by connecting resistor R2 across pins 14 and 15. Resistor R2 is normally left out, but at high input signal levels or high input signal frequency this reduction in threshold may be necessary to prevent instability. Approximately 6 kΩ is a typical starting point; the value of R2 should be as high as possible in any specific case, though.

Tracking range may be controlled by current injection into pin 7 through resistor R3. If R3 is omitted, tracking range will be approximately 15% of center frequency. When R3 is set to a value which permits 0.65 mA of current to flow into the 600Ω impedance at pin 7, this figure is reduced to approximately 3%.

Other controls are possible, but should not be necessary when the PLL is used as

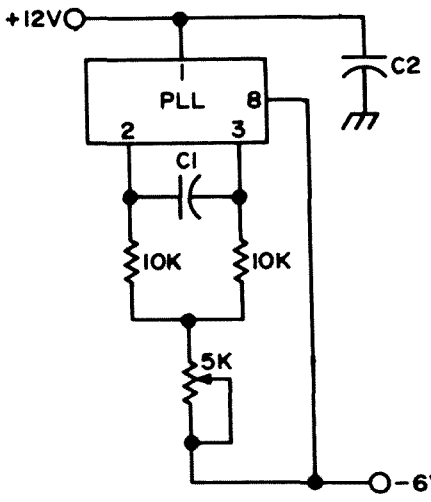

Fig. 5. The NE560/NE561 IC PLL is rated for operation only up to 15 MHz, although many units operate satisfactorily up to 30 MHz. Operating frequency for all units can be increased to approximately 60 MHz by connecting pins 1, 2, 3, and 8 as shown here. This modification can be applied to any of the accompanying circuits. The 5 kΩ pot serves as a fine-tuning control, replacing the current injection into pin 6. If current injection is to be used, the pot can be omitted from this circuit.

an FM receiver. Input signal level should be at least 120 μV to either pin 12 or 13 (the unused input pin should be ac-grounded through a bypass capacitor). Output at pin 9 across a 15 kΩ external resistor (which must be in the circuit; this is an open emitter in the IC) should average 60 mV.

For VHF operation of the PLL, two 10 kΩ resistors and a 5 kΩ pot should be added externally as shown in Fig. 5. According to applications engineer Ralph Seymour, this modification extends the frequency range up to 60 MHz. The 5 kΩ pot provides convenient fine-tuning of center frequency, and may be omitted.

Because of the comparatively high signal level required, and the low input frequency (when compared to the 2 meter band, for instance) a VHF FM receiver for ham use of the PLL would require a converter ahead of the PLL circuit. A block diagram of such a hookup appears as Fig. 6. Note

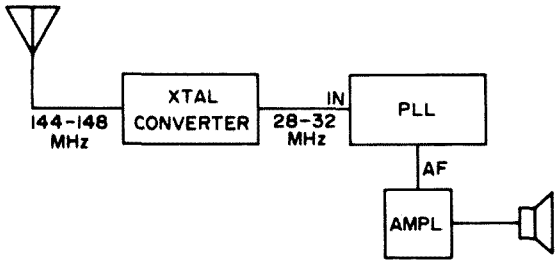

Fig. 6. For ham use as a VHF FM receiver, a crystal-controlled converter ahead of the PLL is necessary. This converter need only provide a moderate output signal level, however, and can be broadband with all receiver tuning being accomplished at the PLL circuit.

that the converter could be crystal-controlled to produce a 28 MHz output; by adjustment of current into pin 6 the PLL can easily be tuned over the full band from a 30 MHz center frequency. This provides, for less than $50, an FM receiver based on the time-honored 75A4 principle of crystal-controlled front end and tunable i-f.

AM Receiver

The AM reception capability of the PLL is something of an "extra." The PLL is

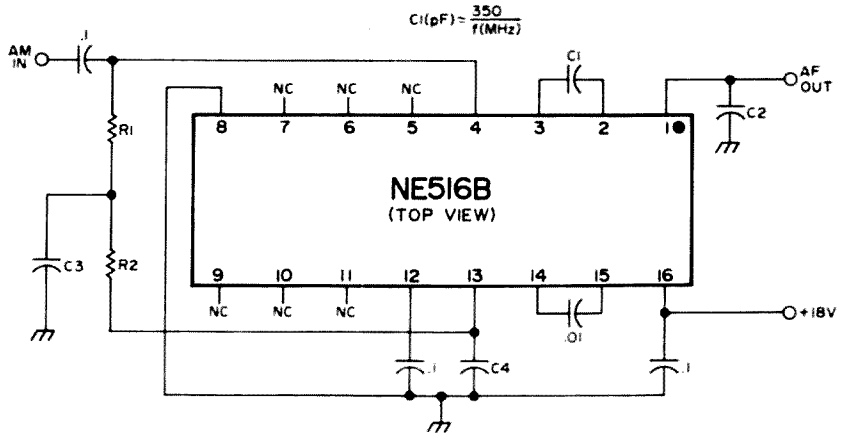

Fig. 7. This is a BC-band AM receiver using the NE561 IC PLL (the NE560 does not include AM detection capability).

locked to input signal carrier frequency and its output is used as the local oscillator to a built-in product detector. A 90-degree phase shift is required to obtain proper operation.

Figure 7 shows the hookup. Bypass and coupling capacitors, all shown as 0.1 μF, should have low impedance at operating frequency (this circuit is intended to cover the BC band rather than HF or VHF). Capacitor C1 is selected to obtain the proper center frequency, and C2 sets the bandwidth by filtering off high-frequency audio output.

The phase-shift network (R1–2, C3–4) provides 90 degrees of phase shift for the rf input signal; the sum of R1 and R2 should be less than 5 kΩ (2 kΩ each was the value used in the prototype) and C3 and C4 should have reactance equal to the values of R1 and R2. For BC operation, 82 pF was chosen.

In this hookup, the low-pass filter is not critical, since no audio is taken from the loop itself; so a simple 0.01 μF capacitor from pin 14 to pin 15 suffices.

Tuning may be done in either of two ways. The first is more straightforward but the second is elegant. The first way is to vary the value of timing capacitor C1. For BC operation, C1 should tune from a minimum of 220 pF (for 1600 kHz) to a maximum of 620 pF (for 500 kHz). The classic receiver alignment technique of padding capacitance is used at the high end of the range, but at the low end varying the current into pin 6 (fine-tuning control) takes the place of adjustment of inductance.

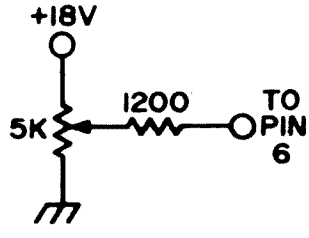

Fig. 8. This simple arrangement for connection to pin 6 of NE560/NE561 provides fine tuning over a 3:1 range. The 1.2 kΩ resistor limits maximum injection current. Timing capacitor should be set for lowest frequency with pot arm at ground, and 1.2 kΩ resistor then trimmed to set highest frequency desired, with pot arm at hot end.

The second method of tuning the receiver uses a fixed value for C1. This value is whatever is required to make the VCO operate at 940 kHz (geometric mean frequency) when the current at pin 6 is zero. Pin 6 is then connected through a 1.2 kΩ resistor to the arm of a 5 kΩ pot (Fig. 8) across the 18V power supply. Varying the pot tunes the receiver across the BC band using only the fine-tuning feature.

This receiver requires an antenna and a good ground; it must get at least 100 μV from pin 9 to ground. Operation will be improved by using a broadband untuned rf amplifier, but care is necessary to assure that the PLL is not overdriven (maximum input signal if 1V rms). Maximum audio output is 2V p-p, and typical output is about 60 mV.

Frequency Multiplication

The PLL IC can be used as a frequency multiplier in several ways. The simplest is merely to set the center frequency to some multiple of the actual input signal frequency. However, as the higher (and thus weaker) harmonics are used for locking, the lock range decreases. If input frequency is fairly stable and rapid tracking is an opportunity for use as a frequency marker. Two PLLs in series could produce a 1 MHz standard from a 100 kHz crystal, and in turn a 10 MHz standard from the 1 MHz standard. One great advantage of the PLL multiplier as compared to a multivibrator or a conventional tuned-amplifier multiplier is that the order of multiplication can be changed merely by changing center frequency (such as with switched timing capacitors). This would permit generation of a 3.5 MHz square wave as the seventh multiple of a 500 kHz standard, giving you strong markers at the bottom edge of every HF ham band.

The PLL multiplier will divide frequency just as easily as it multiplies. If center frequency is adjusted to be one-third that of the input signal, the circuit

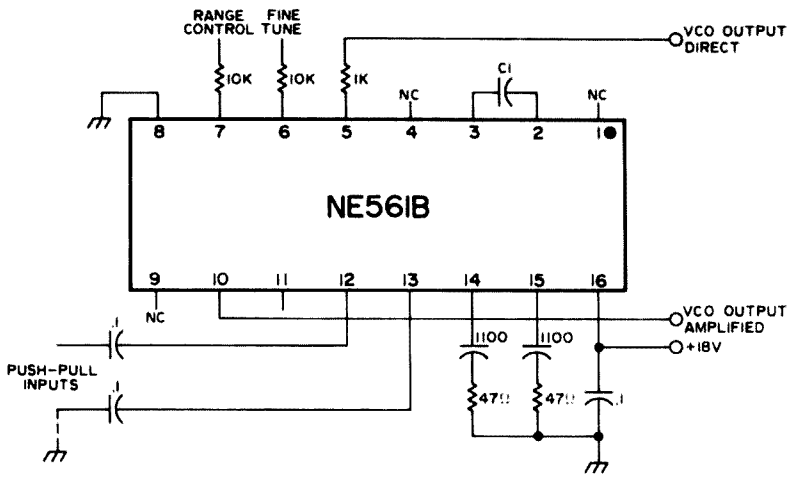

Fig. 9. PLL makes fine frequency multiplier or divider. For this application, audio output connections are ignored and the VCO output is used instead. If input is single-ended, one of the two push-pull input leads should be bypassed to ground as shown by dotted lines. Circuit will multiply up to 10 times, and divide input frequency by 3, 5, 7, or 9. C1 and fine-tuning adjustment must be set for operation near desired output frequency. When input is applied, VCO will lock to exact multiple or odd submultiple of input if it is within locking range and of adequate strength.

not required, this technique can be used to multiply by 2, 3, 4, or 5 times any input signal. Output of the VCO at pin 5 is a square wave.

Action of the PLL as a multiplier can be improved by converting the input signal to a square wave, which has much stronger harmonics than does a sine. When this is done, any output frequency up to 15 MHz can be produced from its tenth subharmonic (multiplication of up to 10 times).

Since the PLL output is already a square wave, rich in harmonics, this offers still locks. This action occurs only for *odd* submultiples, however; for even divisions (half, quarter, eighth) it doesn't work. You can divide 3, 5, 7 or 9 only.

Extensions of these features make possible the construction of simple frequency synthesizers; too many PLLs are required to make them practical at present prices, but when costs come down they may well be worth investigating. Collins Radio's book "Fundamentals of SSB" (out of print since 1962, unfortunately) gives the principles involved if you're interested.

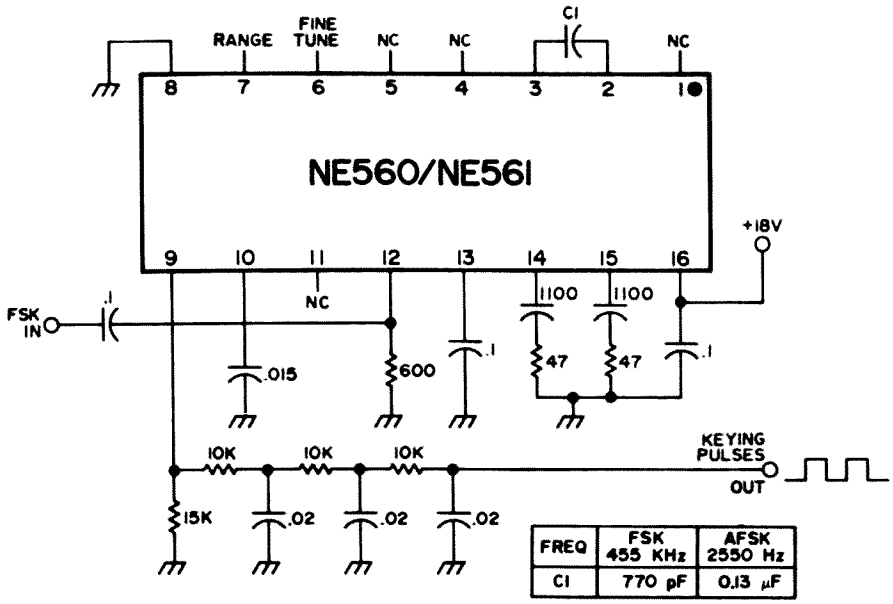

Fig. 10. RTTY converter circuit is taken from computer data set applications note; data set is same as AFSK converter, but gets input signal from telephone line and so is not subject to such high levels of interference as is RTTY. Input may be either at i-f or audio frequencies; table shows values of C1 for both cases. Output consists of pulses which may drive a keying circuit for selector magnets.

The hookup for use of the PLL as a frequency multiplier or divider is shown in Fig. 9.

FSK Converter for RTTY

Using the PLL as an RTTY FSK converter is almost identical to its use as an FM receiver, because FSK (or AFSK) is merely a means of carrying binary or telegraph (mark–space) information by means of frequency modulation. The frequency shift involved is usually rather small – but so is that for FM, in comparison with the center frequency.

The FSK input, either at communications-receiver i-f for FSK or at audio frequency for AFSK, is applied to the FM input of the PLL. The loop filter capacitor is made smaller than usual to eliminate any possibility of "overshoot" in the output pulse,

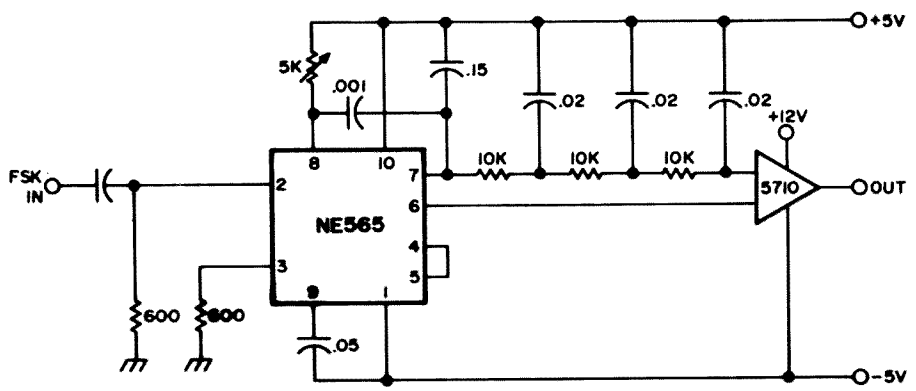

Fig. 11. Alternate RTTY circuit uses NE565 IC, which is so new that its price is not listed yet. Maximum frequency of 565 is 500 kHz. This circuit is designed to drive digital IC devices, and type 5710 voltage comparator is included to adjust output level to values suitable for digital ICs. Pot is for frequency adjustment.

and a three-stage ladder filter removes the carrier component from the output (this is necessary only for AFSK). The center frequency is adjusted to produce about 12V at the output when the input frequency is at its lower figure. When input frequency rises to its other figure, output will rise a maximum of 4V as the VCO tracks the input-frequency change. This voltage change is coupled out through output coupling capacitor to drive any external circuits desired, such as a magnet driver.

The circuit is shown in Fig. 10. Figure 11 shows an alternate circuit using a different type of PLL chip together with an IC voltage comparator at the output to change the output levels to values which are compatible with normal digital IC chips. In this case, center frequency is adjusted to produce a slightly positive voltage at the output, when input is at the low frequency.

SCA Adapter

The PLL's capability to receive FM at almost any center frequency comes in handy if you like background music from the "storecast" services sold by many commercial FM stations. These storecast signals are transmitted as FM of a 67 kHz subcarrier which is itself a part of the normal FM signal. To receive them with the PLL, all you need do is set up the PLL for a center frequency of 67 kHz and tap off an output from your FM receiver ahead of the deemphasis filter (which bypasses the 67 kHz signal to ground) to feed the PLL. PLL output will then be the background music, which is free of all interruptions such as commercials or even station identification.

One precaution may be necessary. The signal from the FM receiver to the PLL input should go through a high-pass filter to prevent any possibility of overload by the much stronger audio of the normal broadcast program or any accompanying stereo information at 38 kHz. A typical hookup using the NE565 PLL is shown in Fig. 12.

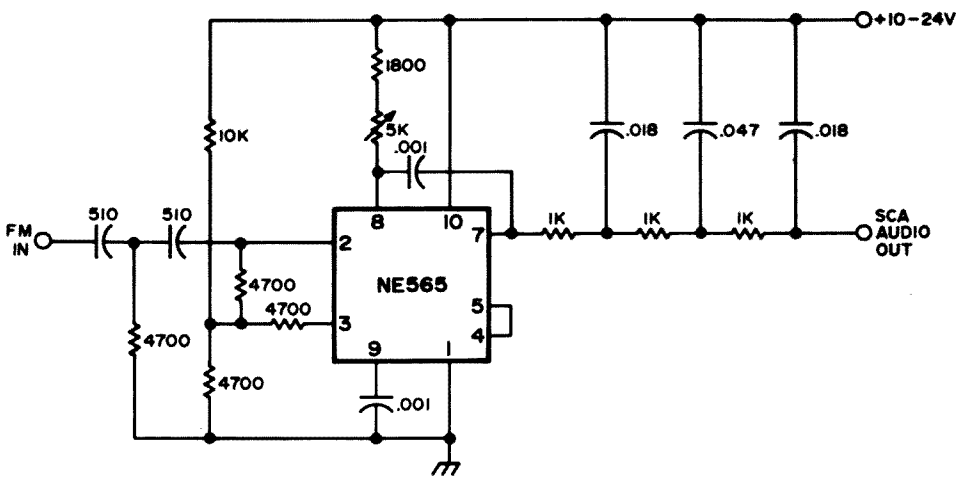

Fig. 12. Background music adapter for FM receivers uses type 565 IC PLL. 510 pF capacitors and 4.7 kΩ resistors at input form high-pass filter to keep audio from FM set from overloading PLL; ladder filter at output removes everything above about 10 kHz to keep from overloading audio amplifiers following. Pot allows frequency to be adjusted to 67 kHz to pick off SCA subcarrier.

The Source

About the only thing we haven't yet told you about the PLL IC chip is who makes it and where they can be obtained.

The manufacturer is Signetics Corporation, a subsidiary of Corning Glass Works and one of the leaders in the integrated-circuit industry for a number of years now. The PLL IC is only one of many chips in their line (their price list as of 4 May 1970 required 21 pages merely to list prices of current IC products).

Signetics is located at 811 E. Arques Avenue, Sunnyvale CA 94086, and we obtained our information from Ralph Semour, linear applications supervisor.

Three ICs Contain Entire Phase-Locked Frequency Synthesizer Loop

Except for the reference frequency component, designers can build the phase-locked frequency synthesizer loop portion of a system using just three IC packages. This is possible through the use of three new Motorola TTL circuits: a dual voltage-controlled multivibrator, type MC4324/4024; a phase frequency detector, type MC4344/4044, and one of two soon-to-be introduced modulo-N programmable counter, types MC4018. These three functions replace from 8 to 15 IC and discrete packages in a conventional phase-locked loop system.

The MC4324/4024 is a monolithic IC that contains two independent voltage-controlled multivibrators (oscillators). The frequency of the MTTL-compatible outputs can be varied over a range of 3.5 to 1 by using a dc control voltage of +1-5V.

The MC4344/4044 is a monolithic phase detector that converts TTL logic levels to a dc voltage level for use in frequency discrimination applications. In operation, the output from either of two internal phase detectors is fed to a charge pump that converts the outputs to fixed-amplitude positive or negative pulses. These pulses are applied to a lag–lead active filter that generates a dc voltage proportional to the phase error between the input and reference signals at the inputs of the phase detectors.

They make the PLL in several different models, with model numbers to match. The one shown in most of these diagrams is the NE561B, which is the most general in application. It includes the AM-detection capability, and quoted price in lots of 1-24 is $37.50 each. The NE560B is virtually identical but does not include the AM detection features, and lists at $30 each. Models NE565 and SE565 (the N indicates *commercial* temperature range; the S means *military* range) are too new to be listed; they operate only up to 500 kHz and so presumably would be lower in cost. The 565 is used in the circuits of Figs. 11 and 12. Finally, the NE562 is intended for direct interface with digital logic systems and, like the 565 it is too new to have an established price yet.

Pin connections for the 560, 561, and 565 are shown in Fig. 13.

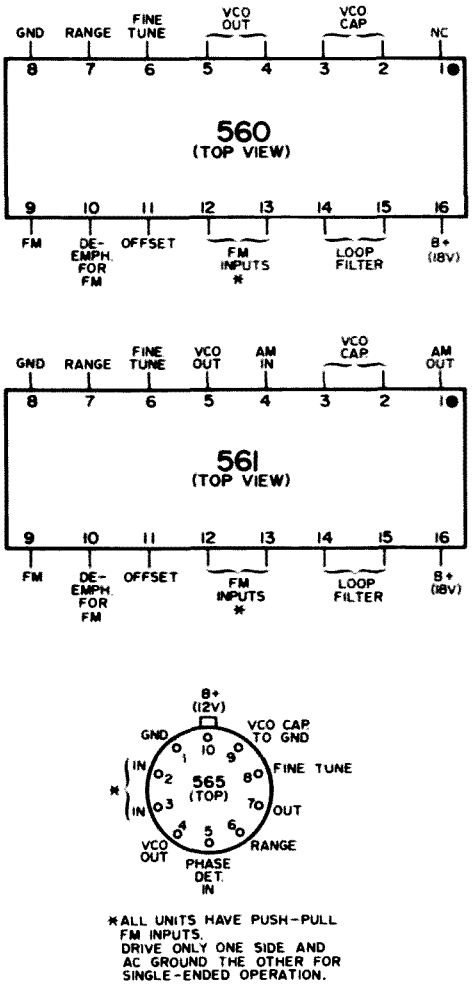

Fig. 13. Pin connections for types 560, 561, and 565 Plls are shown here. Only difference between 560 and 561 is that 561 has Am detector included where 560 has additional VCO output lead.

The N5710T comparator shown in Fig. 11 sells for $2.62 each in lots of 1–24.

All of these (with the possible exception of the 562 and 565, which were still *preliminary* designs at this writing) may be obtained on special order from the manufacturer. In addition, the major mail-order houses catering to the industrial electronics trade may be able to obtain them although no catalog available to us lists Signetics as one of the lines carried in stock (the firm deals primarily with the original-equipment-manufacturer market). Inquiries should be addressed to Mr. Seymour and should mention this article.

A LOW COST FUNCTION GENERATOR FOR THE EXPERIMENTER

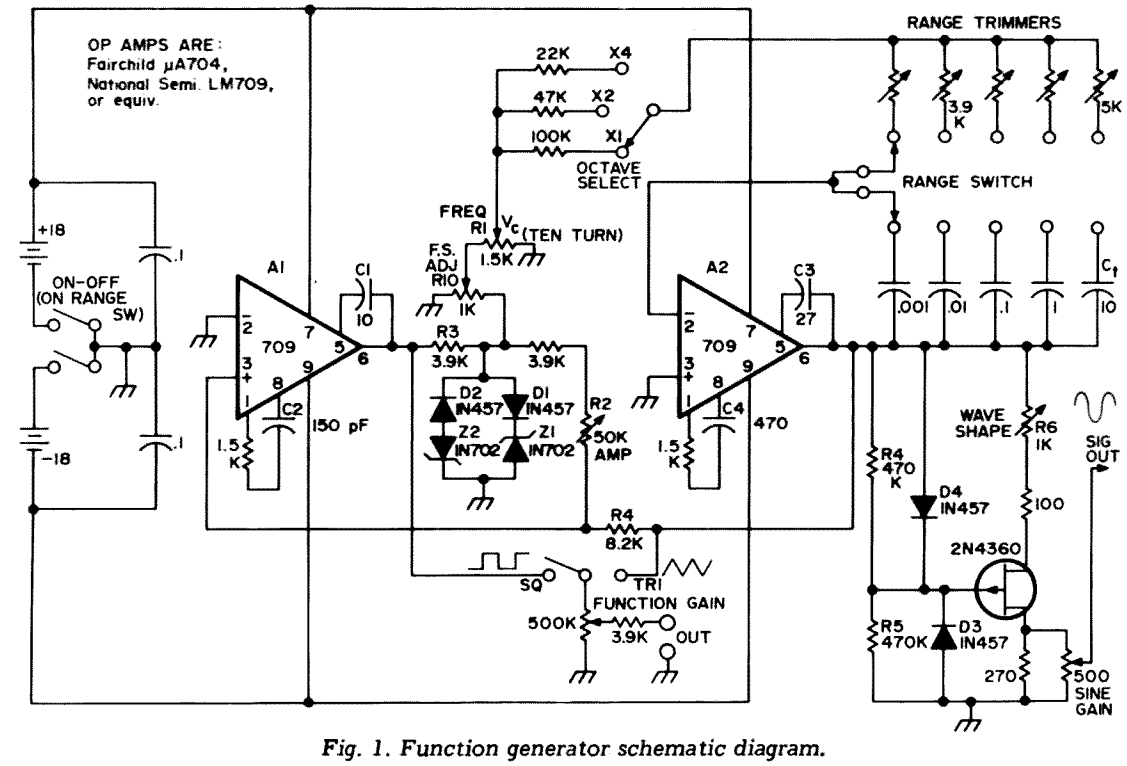
Most experimenters have audio frequency oscillators, yet their use is severely limited by the lower frequency limit of about 20 Hz in most low-cost units. This limitation exists because of the extremely high impedance necessary to avoid loading the frequency determining network. Until the advent of the field-effect transistor (FET) it was almost impossible to build a low-distortion, low-frequency transistor signal generator. It is still difficult to lower the output frequency significantly without introducing severe distortion.

The unit described in this article has none of the low-frequency limitations of bridge-type oscillators. It generates signals in the range of 4 kHz down to about 10 mHz (that's 10 millihertz, or 0.01 cycle per second!). Such frequencies have many uses, such as generating slow-sweep displays, checking the response of low-frequency filters, and voltage-control applications in electronic music generation, instrumentation, etc. The circuitry is similar to that of a high-priced laboratory instrument known as a "function generator," but by taking advantage of low-cost ICs and nonprecision resistors, it can be built for substantially less than most kit-type audio generators.

Circuitry

Most audio oscillators directly generate a sine wave. Sine-wave oscillators usually are much more critical than other types. The oscillator of Fig. 1 generates a triangular wave which is then shaped into a sine wave using a FET instead of a reactive filter. This renders it insensitive to frequency, enabling the distortion to be constant over the entire range. Due to difficulties in obtaining precise symmetry in FET characteristics, plus nonideal characteristics of the transfer function itself, it is difficult to get the distortion lower than about 1.2%. This is adequate for almost all applications.

Integrated-circuit operational amplifiers (opamps) are used to generate the triangular wave. Unit A2 is connected in a circuit arrangement known as an integrator. Time-determining capacitor C_t is charged at a rate directly proportional to the current fed into pin 2 (the inverting input) of the opamp. Pin 2 is kept at ground potential by feedback through the capacitor, so the current equals the voltage at point V_c divided by the total series resistance, consisting of the resistor on the octave switch and the range trimmers. Thus, it is possible to control the charging



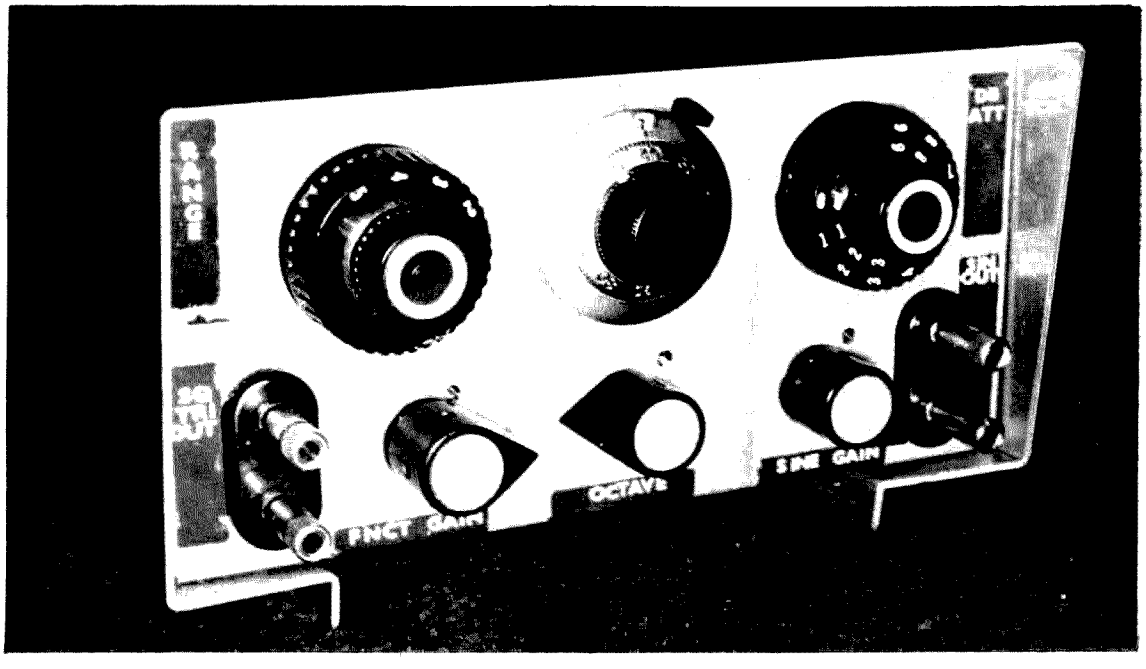


Fig. 1. Function generator schematic diagram.

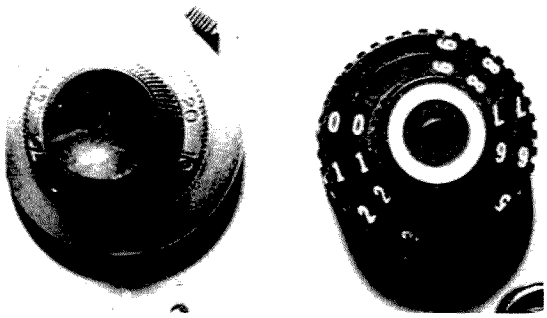
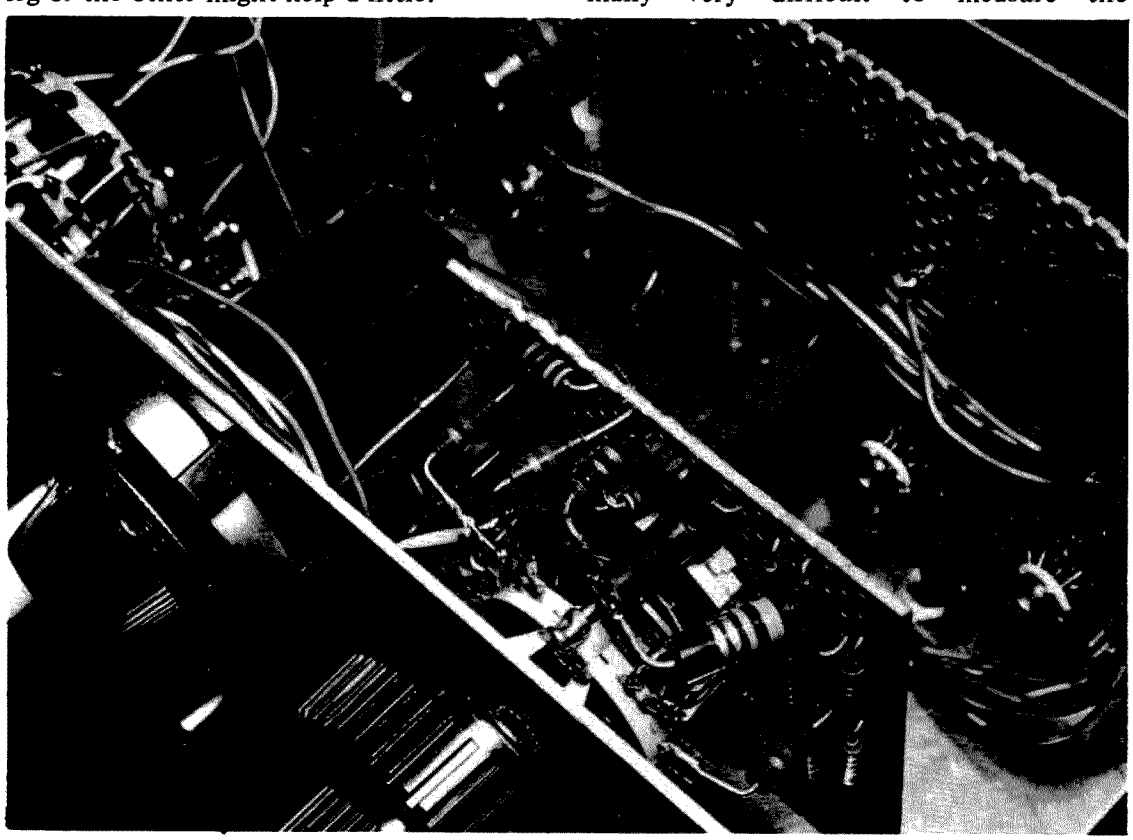
rate with R1, and the high current capacity vs low leakage current of the opamp allows the charging rate, and hence the frequency, to be varied over a 500-to-1 range, compared to the normal 10-to-1 range for normal capacitance-controlled oscillators.

If a current were just fed into the opamp, the capacitor would continue charging until the limit imposed by the opamp and the power supply voltage was reached. However, A1 is connected to the frequency control pot, and supplies the voltage that is converted into the charging rate by the various resistors. A1 is connected in a positive feedback loop with high hysteresis. The opamp is sensitive to the



Front panel of function generator.



voltage between the two input terminals. If the difference is only a millivolt or so, the amplifier goes to either its fully positive or fully negative limit, depending on the input polarity.

Feedback to the input is through R2 and R4. Assume the output of A1 is fully negative. This voltage is clamped to about 4V by D2 and Z2 (D1 and Z1 when positive). This 4V is connected back to the input through R2 (and the 3.9 kΩ protective resistor). As the voltage at the output of A2 gets increasingly more positive, a point is reached where the current through R4 becomes opposite to and slightly greater than that through R2. When this happens, the amplifier instantly (in a few microseconds) changes state, aided by the positive feedback through R2. Of course, when the opamp changes state, the integrator starts to charge in the opposite direction, thus creating the triangular wave. The zener diodes insure that the wave is highly symmetrical. If your zeners are out of tolerance, or distortion is critical, connecting a small resistor in one leg or the other might help a little.

The sine wave, square wave, and triangle wave are all synchronous and available simultaneously. To conserve panel space on my unit, I used a switch to connect either the square or the triangle to the binding post, though this is not necessary. Whatever arrangement you use, avoid loading the output on the opamp by more than about 2 kΩ. It won't harm anything, but the output frequency may change slightly when connecting and disconnecting loads if this precaution isn't observed. It is normally very difficult to measure the

Front panel view of frequency control dial and step attenuator dial.

Interior view of unit with step attenuator resistors in front.

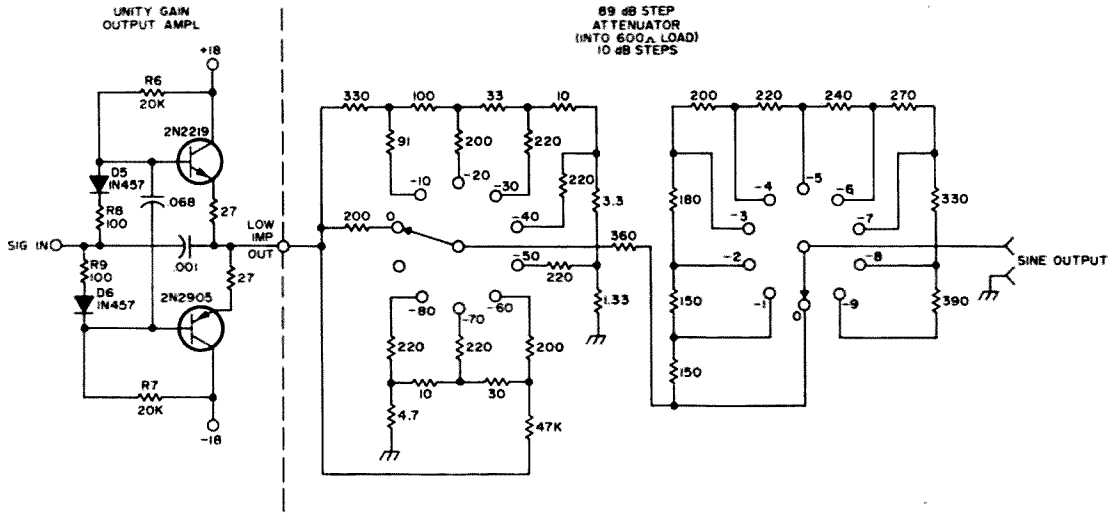


Fig. 2. Output amplifier and attenuator schematic.

frequency of VLF sine waves. Connecting the square wave output to a counter while using the sine output is a great convenience.

The sine wave shaper takes advantage of the symmetry of the source and drain with respect to the gate of the 2N4360 J-FET. (This unit was chosen primarily for its very low cost, as well as its relatively high pinchoff voltage which gives a greater output voltage.) The output of A2 varies symmetrically about ground, and as the absolute value of the voltage increases, the FET resistance also increases due to the gate bias. Incidentally, note that the power to drive the FET circuit is supplied directly by the opamp output. Proper bias polarity is insured by D3 and D4.

Since the output is symmetrical about ground, no coupling capacitors are necessary. It would be hopelessly unwieldy to use one for 0.01 Hz anyway. The output amplifier is designed for unity gain with no voltage offset. Simplicity is achieved through the use of complementary transistors. The output impedance is under 100Ω. Resistors R6, R7, R8, R9, and diodes D5 and D6 are the bias network, which eliminates crossover distortion in the amplifier.

If you plan to use the equipment for checking professional audio equipment, you might desire to add the attenuator shown in Fig. 2. It provides 89 dB of attenuation into a 600Ω load. Two concentric single-pole, 10-position switches break the 89 dB into 1 dB steps.

To simplify the attenuator design and allow the use of standard resistors with 5% tolerance, an unususal circuit was used. The 10 dB steps are provided by a constant-impedance (200Ω) "T" attenuator, and the single dB steps are provided by switching in series resistors. Thus, the attenuator is not of a constant-impedance design, although the voltage into a 600Ω load conforms to the proper setting.

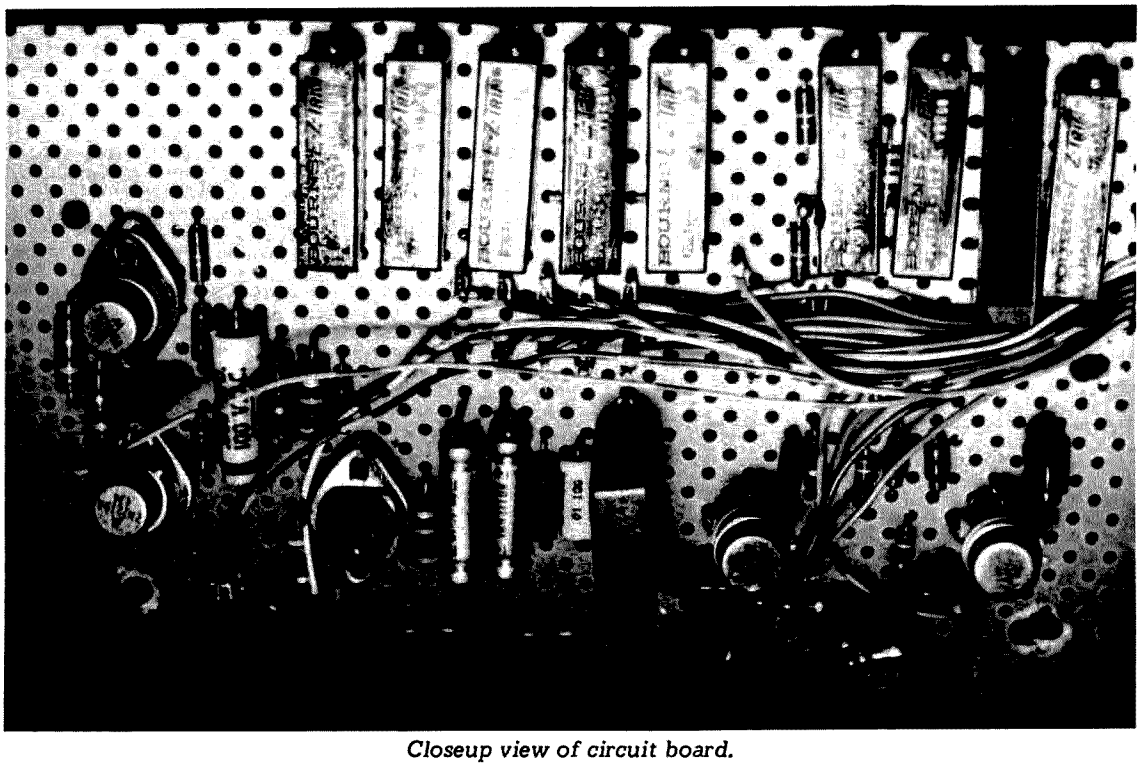
If you are using a high-impedance load, the output should be bridged with a 600Ω resistor. A low-impedance load will exaggerate the effect of the 1 dB step switch.

I emphasize that this whole assembly, while desirable, is purely optional.

Adjustment

As you can see from the photograph, the frequency control is a 100 turn precision potentiometer. These are readily available for a couple of dollars in the surplus market. Using one, it is possible to calibrate the unit so that for the top 900 divisions, the output frequency is correct to within 1%. As the octave select switch is switched to a lower series resistance, the linearity of the frequency control is decreased. The full-scale adjustment pot sets the output frequency to 100 Hz on the range with the .01 μF capacitor when the octave switch is in the X1 position (100 kΩ series resistance). Then the various range adjust pots are set until each range

has the appropriate full-scale value: 1 kHz, 100 Hz, 10 Hz, 1 Hz, 0.1 Hz.



Potentiometer R2 is adjusted so that the triangle amplitude is proper for conversion to a sine. This control interacts with the full-scale adjustment pot, so they both may have to be readjusted several times. Waveshape pot R6 is adjusted for symmetry in the top and bottom halves of the sine wave. A scope or harmonic distortion meter is advisable for the above two adjustments, although a reasonable null can be achieved by a musically trained ear, especially if there is an undistorted signal available for comparison.

Construction

The circuitry is noncritical and any convenient layout may be used. Power is provided by four 9V batteries. Do not exceed this voltage as the operational amplifiers are rated for a maximum power supply potential of ±18V. The batteries should be bypassed with 0.1 μF capacitors.

If any trouble is encountered with the opamps oscillating at high frequency, it will probably be eliminated by bypassing the power supply pins to ground as close to the IC as possible. If this doesn't work, add capacitance to C1, C2, C3, and C4 a few picofarads at a time until oscillation stops. The values given in the diagram are calculated to work with almost all production opamps, but occasionally one will be near the edge of the specifications and require the extra capacitance.

If you don't need precise frequency calibration or attenuation, substantial cost can be saved by eliminating these features. The range trimmers can also be eliminated (just replace with a short circuit). The octave switch can be replaced with a fixed resistor down to 15 kΩ or so. The output attenuator can be replaced with an ordinary pot; and substitute the 500Ω pot and 470Ω opamp resistor before the amplifier with a 240Ω resistor; and connect the opamp input directly to the FET. The pot must be connected to the amplifier output to attenuate the amplifier noise as well as the signal. Use any convenient pot for the frequency control, and calibrate the dial yourself.

Closeup view of circuit board.

Following these procedures can reduce the cost to under $10 and yet provide you with an oscillator that, in the lower frequency ranges, is better than anything selling for under the price of a laboratory function generator.

CONTROLLING Repeaters WITH TONES

by Ken W. Sessions, Jr. K6MVH

A few years ago, an amateur repeater typically consisted of not much more than a transmitter and a receiver, interconnected to operate as a repeater. But a number of factors have served to bring about a trend toward limited control of the repeater through the use of audio tones transmitted on the repeater's input frequency. When two repeaters are close enough to one another so that a user station triggers both repeaters when he attempts to use but one, a tone system is called for. When a group of amateurs band together to put up a repeater for the exclusive use of material supporters, again tones are required. When the repeater input frequency is commonly used for a simple channel (point-to-point, or direct), a tone system is the only way to insure that the repeater is only triggered when it is actually being used by one of the stations on the frequency.

Today, the toned repeater is at least as common as the straight "carrier-operated" repeater, and the trend towards tone control is certain to increase from here on out.

The three most common methods of tone control for amateur repeaters are, in order of popularity, "tone burst," "whistle-on," and "continuous-tone-carrier-squelch." The first two systems employ the use of a relatively high-pitched audio tone of short duration. The latter employs a continuously transmitted very-low-frequency "subaudible" tone of a specific and usually quite critical frequency. Each system has advantages the others do not share. It is up to the repeater designers to look at the merits of the three systems, then adopt the one that best meets their particular needs.

A tone-burst system installed in a repeater will require each user to transmit a short tone "burst" each time he wants to communicate through the repeater. The only practical method of utilization in such systems is for each user to install a tone oscillator in each of his transmitters, along with a simple timer to limit the duration of each tone burst, and a method for automatically keying the oscillator each time the transmitter push-to-talk circuit is actuated. Each user should also install a switch so that he can take the tone oscillator out of the circuit when he is not operating through the repeater.

But on the plus side, the tone-burst system is the simplest of all the systems to install at the repeater; it will consist of nothing more than a single relay and a

timer to limit length of each transmission (assuming that a tone decoder is already installed at the repeater site).

The whistle-on system is the nicest from the standpoint of the users, who must possess no oscillators other than the one with which they were born. A simple brief whistle will turn on the repeater, and the repeater will operate from that point on in a purely carrier-operated manner. After a specified time period of inactivity (say, no incoming repeater signals for five minutes), the repeater will shut down. To turn it on again, the next user will have to command it with another orally produced whistle. As with the tone-burst system, the whistle-on approach includes a transmission-limiting timer of a minute-and-a-half or so.

The whistle-on concept offers the most in terms of flexibility, but it requires two timers and a relay (in addition to the broad tone decoder). Interconnection, however, is quite simple.

The third approach, continuous-tone-carrier-squelch (most frequently referred to by Motorola's tradename of *PL*, for "Private Line"), is the least flexible, the most difficult to implement, and the most critical with respect to audio stability. It is also the most secure of the three, which is one of the reasons many amateurs elect to use this system for their "closed" repeaters.

There is little complexity at the repeater site with a PL system, since nothing other than the decoder itself is actually required, even though most amateurs like to add a delayed-dropout relay to avoid "chopping." But the problems faced by the users are manifold. Here, every transmitter that is intended to be used with the system must be equipped with highly stable low-frequency tone generators. And, unless great care is taken in the setup of all the stations, the repeater in use will sound like a bunch of stations who use unfiltered power supplies. A good PL system should be subaudible, but amateur setups – commercials, too, for that matter – seldom are.

Basic Control Logic

Once the type of tone access approach is chosen, the repeater should be set up to provide the widest possible number of logic outputs, which can be used for an almost endless array of later control functions. The tone decoder, for example, should drive a relay to provide voltage and ground outputs when the proper incoming tone is sensed. And the carrier-operated relay should likewise be set up to drive a multicontact, heavy-duty "slave" that provides voltage and ground output signals for both the *signal* and the *no signal* states. These logic signals will prove invaluable as additional control functions are implemented.

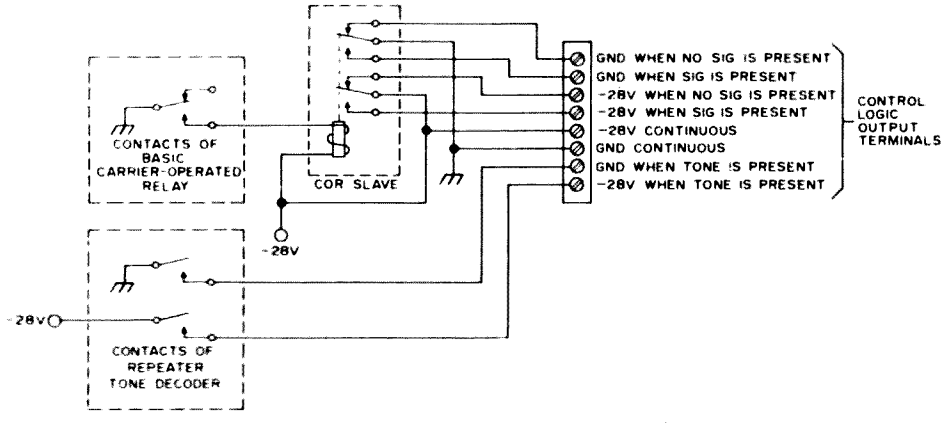

Fig. 1. A heavy-duty relay slaved to the carrier-operated relay, along with ground and voltage outputs from the tone decoder, can be used to provide a variety of very useful logic signals for all repeater control functions.

The circuit of Fig. 1 shows how the logic signals are obtained and what they are. The control circuits described here and in other "repeater control" articles will always require at least some of the logic signals available on the terminal board.

Control Logic and PL

A good example of how the logic signals can be used appears in Fig. 2, which is the heart of a PL control system. The coil of a delayed-dropout relay is fed with the ground output of the tone decoder and the voltage output from the carrier-operated relay. If the tone is erratic, the relay stays keyed because of the timer's delay of a half-second or so. But, since the carrier-operated relay ground output signal is used to key the transmitter push-to-talk circuit directly (through the contacts of the delay relay), any loss of signal will cause the repeater to shut down immediately. Thus, there is no "delayed squelch" arrangement, yet the users are protected from fluttering of the repeater that might be caused by borderline settings of their tone units.

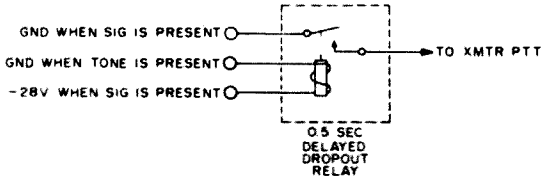

Fig. 2. There are many methods for keying continuous-tone-carrier-squelch (PL) systems, but those employing delayed dropout relays are the most successful. Here, the tone and the signal must be present to hold the repeater on the air. Momentary tone variations because of weak signal will not cause "cycling" because of the delay, but the repeater will drop out instantly if the carrier itself drops out.

Control Logic and Tone-Burst

The relay and timer circuit of Fig. 3 shows how the basic repeater logic signals can be used to control the tone-burst repeater. When a signal appears without the proper accompanying tone, the normally open contacts of the repeater control relay keep the COR ground signal from being fed to the repeater push-to-talk circuitry. When the correct tone appears, however, a ground signal from the tone decoder energizes the coil of the repeater control relay (whose voltage is supplied through the normally closed contacts of a 1.5-minute timer). The control relay pulls in and is latched by the COR ground signal now being supplied through the relay's own contacts.

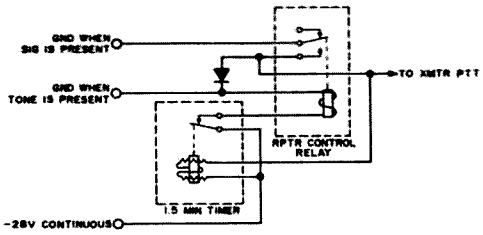

Fig. 3. Tone-burst repeaters can be set up with nothing more than a relay and a timer if the decoder and COR logic signals are available. Here, a short tone burst will energize the control relay, which latches as long as a carrier stays on the input. If the carrier stays on more than 1.5 minutes, the repeater will go off the air and a new tone will be required. Each transmission must be accompanied by the proper tone burst.

Even though the tone burst is short, the repeater control relay will keep the transmitter on the air as long as a signal stays on the input frequency – unless that time period happened to exceed a minute-and-a-half.

The timer is keyed at the same time the push-to-talk circuit of the transmitter is energized. And if the same signal is present for the timer's full period, it will pull in to break the circuit on the repeater control relay. The only way to get the transmitter on the air again if this occurs is for a new carrier to come on the frequency with the proper tone.

The control relay also drops out when any carrier disappears, so that each station who wants to use the repeater must either "tail-end" (seize the frequency before the preceding user drops his carrier) or be equipped himself with the proper access tone burst.

The diode in the circuit, by the way, is to keep the tone decoder ground signal

from being overworked. Without the diode, the decoder ground signal would have to key the transmitter push-to-talk and the transmission-limiting timer. With the diode, the tone decoder ground can only trigger the repeater control relay.

repeater will shut down. Another whistle must be sent to bring the repeater on again.

As with the tone-burst system, a timer is typically employed to limit the length of transmissions going through the repeater. Figure 4 shows the circuit and the logic

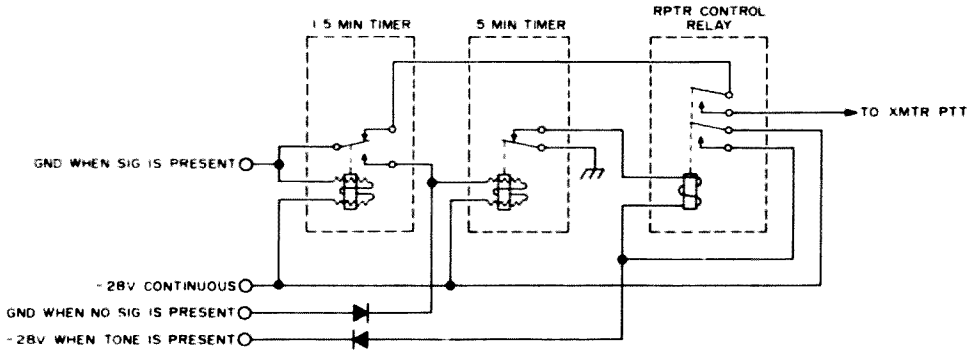

Fig. 4. The complete whistle-on control system contains two timers and an ordinary relay. If a carrier stays on for more than 1.5 minutes, the push-to-talk circuit is disconnected. If the carrier stays on 6.5 minutes, the repeater shuts down and must be whistled on again. Also, if nobody uses the repeater for 5 minutes, shutdown will occur.

Control Logic and Whistle-On

Not many people really understand the "whistle-on" approach. Some amateurs seem to think that if they can whistle to bring a repeater on the air, that process constitutes a whistle-on system. However, in spite of the fact that many tone-burst systems can be accessed by a whistle, a true whistle-on system is one that has been designed for access by whistling. And to be convenient, no whistle approach can require the users to whistle each time they transmit.

A whistle-on repeater may stay off the air for long periods. Stations can transmit as much as they want on the input frequency, but no repeater will be around to assist in their communications unless one of the users decides to call up the repeater by uttering a brief whistle. When the tone decoder at the repeater senses the presence of the whistle, on comes the repeater, *as a conventional carrier-operated system as long as the repeater is active with users.*

When the users all drift away, and the repeater becomes inactive, the repeater starts counting time. After a specified period, usually five minutes or so, the

required to produce a sound whistle-on repeater system.

Normally (when the repeater has not been whistled on), incoming signals cannot be fed to the push-to-talk because the COR ground signal goes no further than the normally open contacts of the repeater control relay. When the whistle is sensed, however, decoder voltage causes the control relay to pull in (and latch). Now all signals, tone equipped or not, will be repeated.

When a single transmission exceeds 1.5 minutes, the COR ground signal causes the timer to pull in and disconnect the push-to-talk. If the user was simply longwinded, he'll quit transmitting in a minute or two and the system can go right back into normal operation, with no new whistle required. But if the problem is more serious than a longwinded ragchewer, the whole repeater will shut down completely in five more minutes. The COR ground is rerouted after the first minute-and-a-half to the five-minute timer, which causes de-energization of the repeater control relay at the end of its period.

The five-minute timer is also used to shut down the system when nobody is

DUAL GATE MOSFET
PRE-AMPS

to 175 MHz. $21.95 ppd.
to 300 MHz. $25.95 ppd.

NEW FOR 1970!
The above models now have rf gain control.

For 300 to 470 MHz
See Model 202 in our catalog.

- Available from 5 MHz. to 450 MHz. Bandwidth is approximately 3% of frequency.
- Voltage gain 30 to 40 DB depending on frequency.
- Two Dual Gate MOSFET amplifier stages with each having a tuned input and tuned output. Each Dual Gate MOSFET is actually an integrated cascode circuit thus giving you 2 cascode circuits equivalent to 4 triodes.
- Exceptionally low noise (2.5 DB at 175MHz.), greatly reduced cross modulation and 10 times the dynamic range (signal handling capability) of the best bi-polar transistors. Also superior to preamps using junction FETs and Single Gate MOSFETs.
- Internal connections for high impedance AGC or manual gain control if needed.
- Type BNC input and output receptacles for minimum loss at UHF. Standard impedance is 50-75 ohms.
- Carefully tuned at our laboratory with sweep generator and oscilloscope for the best bandpass characteristic.
- Full wave UHF diodes protect input transistor.
- Operates on 6 to 16 volts DC, 5 to 15 Ma.

New York City and State residents add local sales tax.

using the repeater. A ground signal from normally closed contacts on the COR slave relay completes the circuit on the timer coil. This "double duty" provides for an extremely safe and self-controlling repeater system.

As with the tone-burst circuit, the diodes in the whistle-on system are for isolation. The one in the *no signal present* ground line keeps the circuit isolated from the *signal present* logic. The diode in the negative voltage line isolates the *tone present* signal from the *continuous −28V.* terminal.

Tone Access and the FCC

The Federal Communications Commission has been riddled with requests from amateurs seeking to get a relaxation in the rules governing remote control and general operation of repeaters. The indications are quite strong that the relaxation may come, but not until repeater designers and builders prove beyond doubt that effective, failsafe, and adequate measures for autocontrol and subcontrol (tone access) can be demonstrated.

The need for monitoring from a fixed UHF facility has been challenged by amateurs and defended by the FCC. Commission spokesmen say they will not even consider allowing unmonitored repeaters, or control from a mobile, until a positive means can be shown for providing certain, reliable control under all operating conditions. Tone-access repeaters with backup timers for passive control are a giant step toward meeting this goal.

Ed. Note. A series of three articles describing tone generators and decoders appeared in 73 Magazine, Feb 1970. The series includes "Encoders for Subaudible, Tone-Burst, or Whistle-On Use," by John Gallegos (W6ZCL), "Tone Decoders for Remote Switching Applications," by Ken Sessions (K6MVH), and "Setting Up the Tone-Burst System," by Les Cobb (W6TEE). The reader is referred to this series for encoder and decoder circuits and for installing tone units into user transmitters.

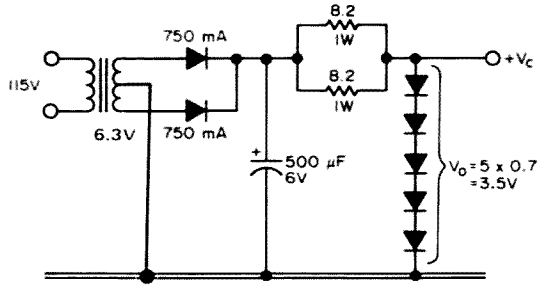
SIMPLE REGULATED POWER SOURCE FOR ICs

Integrated circuits and some transistor units require low supply voltages at relatively high currents. While dry cells can meet the requirement temporarily, serious work and finished units are conveniently fed with line-operated supplies. The usual answer is a transistor regulated supply often more complex than the device it feeds.

The circuit shown in Fig. I was designed to supply an IC logic section of a business machine. It would make a compact low-cost supply for an IC keyer or for general experimental work.



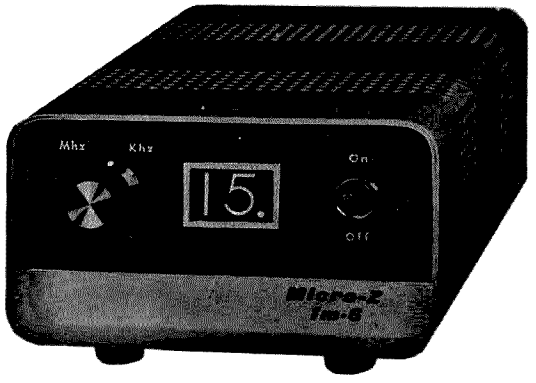


Fig. 1. Simple regulated power source for IC s.

Basically, it takes advantage of the 700 mV forward voltage drop of silicon diodes which varies only slightly with current change. A little time spent selecting individual diodes can provide a regulator for the exact voltage desired, including those values for which standard zeners are not available. Best of all, it can be assembled from parts commonly lying idle, thus freeing the regular bench supply for more demanding work.

The 4.1Ω limiting resistance provides short-circuit protection for the 750 mA rectifiers, and is a necessary part of the filter circuit. A load current variation from 0 to 50 mA causes a supply drop of just 1.65%. To improve regulation at higher currents, increase the size of the filter capacitor.

A SOLID-STATE 10-MINUTE TIMER

Walt Pinner WB4MYL
7304 Lorenzo Lane
Louisville KY 40228

This 10-minute solid-state station timer is a simple economical, one-evening project whose application is only governed by your imagination. An indicator is illuminated by a *set* button and burns for 10 minutes before extinguishing, thereby reminding you longwinded ragchewers or break-in operators to identify as required by the FCC. The unit, made up of 11 components, is installed inside my SB-100 transceiver with the indicator lamp located behind the main tuning dial, where it is readily visible (eliminating the need for hole drilling).

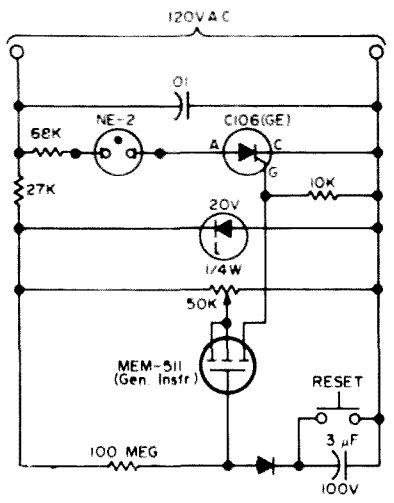

Fig. 1. Schematic diagram of the MOSFET 10-minute timer.

As shown in the circuit diagram (Fig. 1), the heart of the unit is a MOSFET which gates an inexpensive SCR to turn on an indicator lamp (or, if you prefer, energize a relay). Voltage pulses are applied to the transistor and the RC timing circuit, 100 MΩ low-leakage diode, and a 3 μF 100V capacitor.

When 6V appears at the capacitor, the FET is turned off, turning off the SCR and the indicator lamp. Pressing the *set* switch discharges the capacitor, recycling the circuit for an additional 10 minutes.

Because the circuit is line-operated, all components should be isolated from the chassis. In view of the high impedances

involved do not attempt to measure voltages, as any but the most sophisticated test equipment will load the circuit.

Caution . . . The FET is supplied with a shorting wire around its leads; this should remain in place until the transistor is soldered in the circuit.

Precise timing is adjusted with the 50 kΩ pot, which will compensate for component tolerances. Any neon panel indicator with a built-in resistor can be used in place of the NE-2 and 68 kΩ resistor. Color the bulb to contrast with existing panel lighting. Should you wish to power other dc loads up to 2A merely substitute your choice for the lamp. For loads in excess of 2A, the NE-2 may be replaced by a 115V ac relay with a series 600Ω 10W resistor and filter (Fig. 2).

The 600Ω resistor limits the direct current through the ac relay to a safe level, and the 20 μF capacitor insures that the relay will remain on during the half-cycle the SCR is off. The reset switch may be any unused contacts on your rig, such as spare positions on your 100 kHz calibrator switch. It may also be convenient to replace a control with one having a pull switch, thus eliminating the need for hole-drilling should you wish to preserve the original appearance of your equipment.

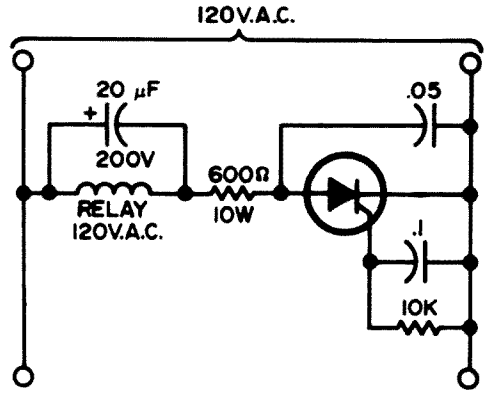

Fig. 2. A relay and associated filter network may be used as shown for switching loads in excess of 2A.

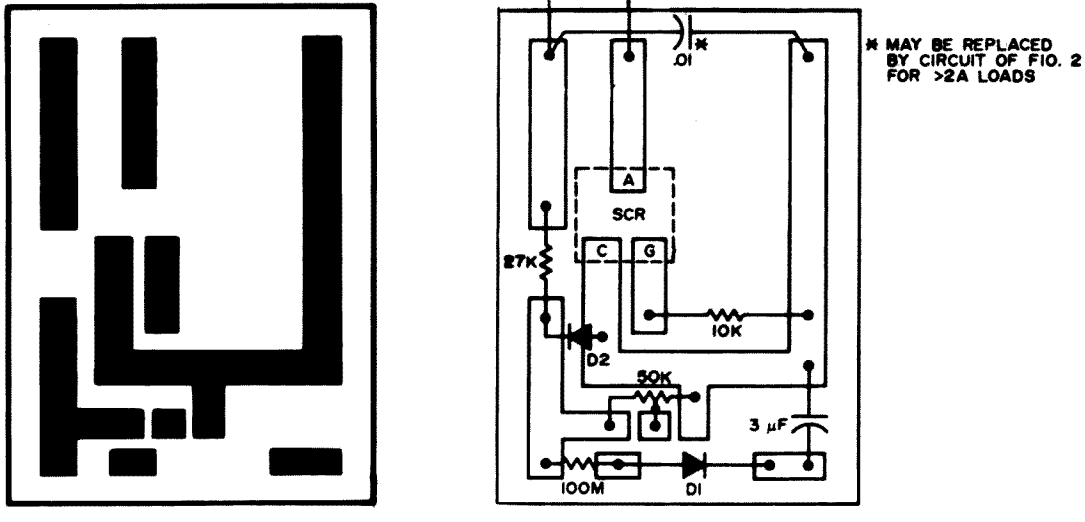
Wiring is not critical and a circuit board (full size) is shown Fig. 3. After soldering, it is suggested that all connections on the board be cleaned with a solvent such as nail polish remover to eliminate leakage via flux, etc. The zener and low-leakage diode were obtained from surplus boards. The SCR is not critical, and any type with 120V ratings that will trigger at 0.8V is acceptable.



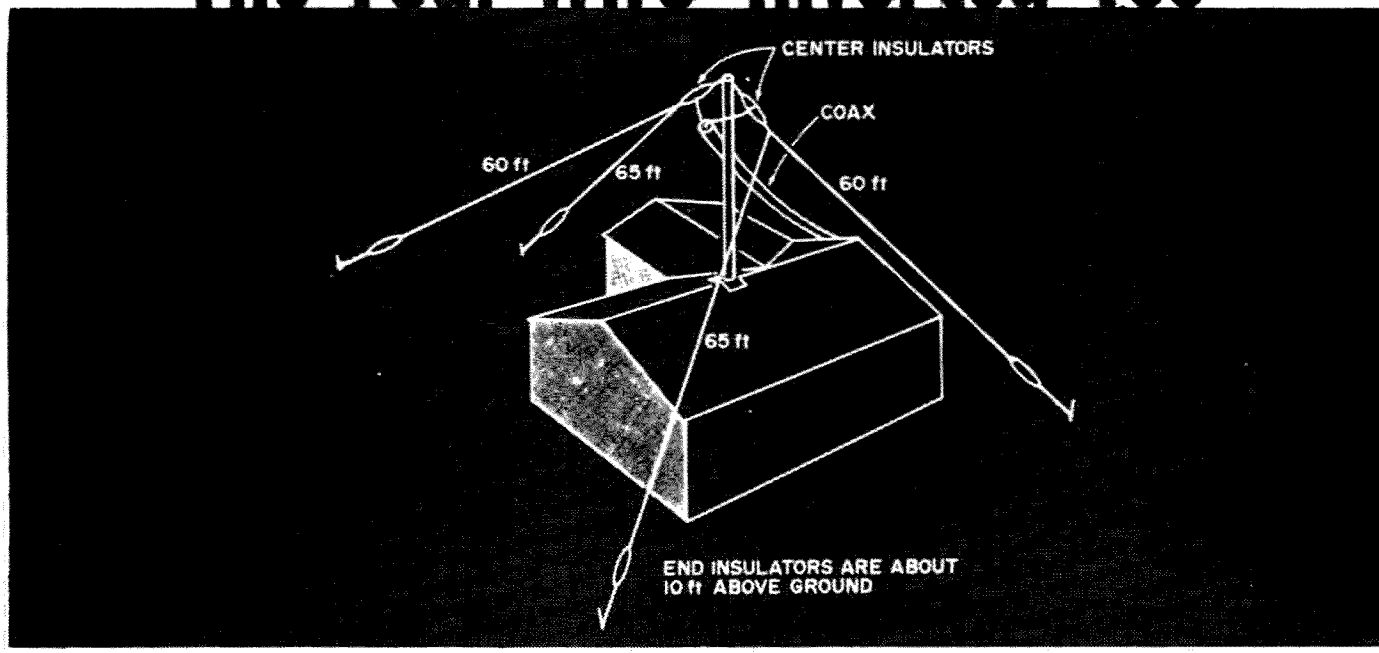


Fig. 3. Layout is shown actual-size alongside a composite view which gives component placement data.

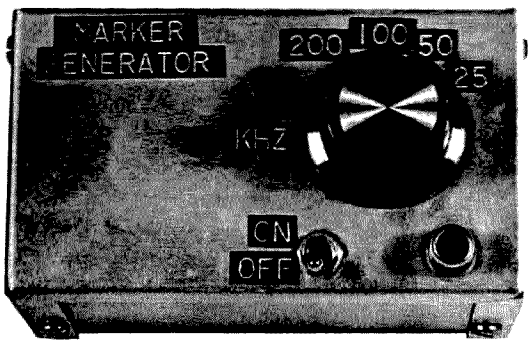
The Four-Wire Inverted Vee

In a search for a better broadband antenna for 80 meters, I have devised one that works beautifully for me. Since it is possible that some of our readers might also be interested I will attempt to describe it to you.

I call this antenna the Four-Wire Inverted Vee, as that seems to best describe it. In the past I have used the conventional inverted vee on the lower bands with good results. This one seems to work better for me. Each side of the vee consists of two wires, one 60 ft long and one 65 ft long. This gives me one conductor near resonance at the top of the band and one near resonance at the bottom of the band. The center of my antenna is about 35 ft above the roof of my house (on top of a 40 meter vertical) which gives me an overall height of about 50 ft.



The best feature of this antenna is that it is coax fed with RG-11/U and tunes the whole band with a very low vswr. If it were fed with RG-8/U, the vswr might be even lower. Any rate, the highest vswr indication was 1.5:1 at 3.8 MHz. My measurements were all made with homebrew equipment that shows a good null on a Heath antenna. While the measurements are not precise due to the fact that 75Ω coax was used (rather than 50Ω), they are close enough to prove the effectiveness of the antenna system.

I have been using this antenna for the past six months and have achieved good results on both CW and RTTY. While I don't operate SSB since the funny license plan went into effect last year, I do want to point out that the antenna loads well in that portion of the band and should give the same results as at the bottom end. While I have not attempted to guess at the radiation pattern, I have worked a good many states on RTTY since I installed the Four-Wire Inverted Vee.

Frequency, MHz	Vswr with 50Ω bridge
3.5	1:1
3.6	1:1
3.7	1.35:1
3.8	1.5:1
3.3.9	1.22:1

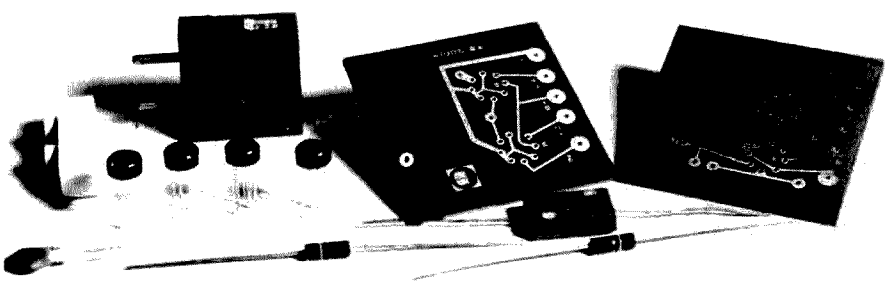
AN IC MARKER GENERATOR



D.A. Poole K4BBC
1223 Brookwood Drive
Winston-Salem NC 27106

Simple IC device gives marker signal when you approach the edge of your authorized band.

The incentive licensing regulations have created a need for identifying restricted band segments. The easiest method of doing this is by using a crystal-controlled oscillator to provide marker signals at the edges of the subbands (getting the Extra license is another good approach).

The marker generator described here provides calibration signals at 200, 100, 50, and 25 kHz intervals, usable up through the 6 meter band. Although the basic components shown were purchased in a kit (R&R Electronics, December, 1969. 73 Magazine) containing the two circuit boards, the generator could be

R&R (311 E. South St., Indianapolis IN 46225) supplies all components and PC boards in kit form.

built on perforated board from individually purchased components.

The circuitry consists of a 200 kHz oscillator and three divide-by-two stages. In the oscillator, a Fairchild μL 914 integrated circuit is connected as a crystal-controlled multivibrator. A 200 kHz crystal is used because it is cheaper and more stable than the 100 kHz crystals usually used in marker generators. With the values shown the frequency is within a few cycles of zero-beat with WWV.

The output from the 200 kHz oscillator is successively fed to three μL 923 integrated circuits, each connected to divide the frequency by two. A rotary switch selects the desired output. Three penlight cells supply the 4.5V required by the integrated circuits.

The generator in the photo was built in a 4 x 2¼ x 2¼ in. aluminum box. The printed circuit boards with integrated circuits are attached to the box with screws and small spacers. The small rotary

The finished marker generator. Note that penlight cells mount handily in cover section of minibox.

switch, battery holder, and output jack are from Lafayette.

The generator has proved to be reliable and stable, providing subband identification at a flick of the switch. Because the harmonic output of the divider is quite strong, tight coupling to the receiver or transceiver is not necessary. Good results can usually be obtained by slipping the end of the output wire down into the shield of the first rf amplifier tube.

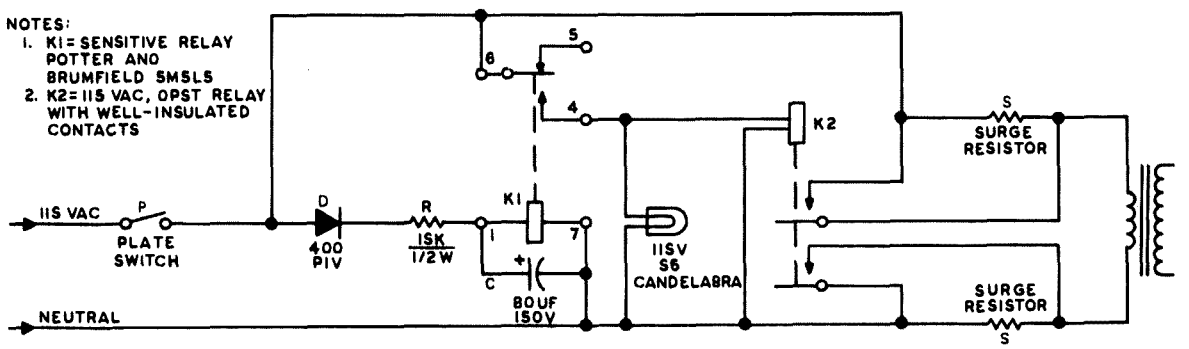
IMPROVING REGULATION IN HIGH VOLTAGE SUPPLIES



Some improvement in the regulation of a high voltage semiconductor power supply system with capacitor input can be obtained by shorting out the protective surge resistors placed in the secondary leads of the power transformer by means of a delay circuit. The amount of improvement, naturally, depends on the values of the resistors.

One method of accomplishing this objective is shown in the diagram.

When the plate switch in the primary of the high-voltage transformer is closed, the RC time constant provides a delay of about one second before the contacts of relay K2 close and short the surge resistors. Variation in delay from milliseconds to several seconds can be achieved by choosing values of R between 10 and 20 kΩ and/or substituting different values of C.

Since the time constant in the filter circuit of the power supply is so small, a delay of one second is sufficient to provide ample protection in shorting out the surge resistors when the power is turned on. A 115V isolating transformer must be used between the plate switch and the diode if the 115V line polarity is not observed.

Louis Berman K6BW ■

STUDY GUIDE GENERAL CLASS LICENSE

PART III

And more power to you.

It may seem that we're putting too much emphasis, in this study course for the General license examination, on the ultrabasic fundamentals of electricity and electronics. After all, nearly three-quarters of all the questions on the FCC's official "study list" deal with matters much more complex than those we have been examining since we began.

However, our stress on the ultrabasics is deliberate. With a strong understanding of the major principles of electrical physics as a foundation, the more specialized matters met on the actual examination will be much more solidly seen. In other words, we're going a bit slowly at the beginning, so that we can do a better job later on and make it all appear to be as simple as it really is.

Already covered has been the propagation of electromagnetic energy, through both wires and space, as well as the ideas of voltage and current, resistance and reactance, and Ohm's Law for both ac and dc. We're now ready to attack such puzzlers as power, decibels, and harmonic frequencies.

Specifically, this time we're going to look at the following three questions from the FCC study list (the numbers are those appearing on the official list):

15. What is a decibel?

16. What is a harmonic? List ways of minimizing harmonic generation in frequency doublers, vacuum-tube amplifiers, transmission lines, and antennas.

30. Define instantaneous power, average power, sideband power, audio power, and peak envelope power. How is each related to the voltage and current that produced it? How is each related to the unmodulated carrier power?

Most of the questions that appear on the official study list are extremely specific ones dealing with some narrow aspect of a general subject, and to provide you a broader base of knowledge we have followed the practice of rephrasing the questions into more general forms.

This time, we'll do that with two of them – but one is already about as general as it can get.

Our questions, therefore, will be a mixture of our own rephrasings, and the study list question which is already general. We'll start by asking "What is Power?", which will build us a bridge from what we already know about energy, voltage, and current, to the many ways in which power can be specified. We'll follow that up by learning "How is Power Measured?" to determine how the various kinds of measurement and specification of power relate to each other. Next, we'll find an answer to "What is a Decibel?" – and in the process we may be able to remove some of the traditional confusion which always seems to surround this subject.

We will then direct our attention to harmonics, asking first "What Are Harmonics?" and then "How Can Harmonics Be Controlled?" By the time we complete our look at these, you should know more than you really wanted to about the subject.

What is Power?

"Power" is one of those words we all *think* we know the meaning of – and because of this, it's extremely important that we be sure right at the start of our studies of electrical power that we're all using the *same* meaning for the word.

Dictionaries list many meanings for power. In everyday conversation, we speak of political power and powerful motors, of the power of public opinion, and the power of the individual. There's the power we get from the wall plug, and the power to keep going we get from our food. All of these are different kinds of power.

So let's ignore what we think we know about the meaning of the word, and develop a brand new definition to use during our examination of this subject. Let's begin by going back to what we learned in the first chapter of this course, about current and voltage.

There, you may remember, we found out what "current" and "voltage" were by relating them to the two kinds of energy involved in the magnetic field and the electric field. We found that either of these two kinds of energy ("actual energy" and "potential energy") could apparently exist indefinitely by itself so long as nothing moved, but that as soon as "motion" came into the situation the total energy present began changing from one form to the other, and that this change of form of the energy was what we know as "electric" and "magnetic" effects.

While we didn't bring it out in so many words at that time, "motion" itself involved the use of energy – which might mean that putting motion into our balanced situation simply unbalances it by adding additional energy. This is one of the areas in which physicists are still uncertain as to exactly what goes on, but the assumption appears reasonable in view of the current belief that everything in existence is either energy, or equivalent to energy, and that the total amount of energy in the universe cannot increase or decrease but must remain forever unchanging.

What all of this means to us at this point in our studies is simply that any use of electricity involves a use of energy.

We also found, earlier, that resistance in a circuit causes some of the electrical energy present to be dissipated in the form of heat – which, again, is another kind of energy. If it won't cause too much confusion, we can consider that electrical energy which is changed to heat energy has been "used up"; we do not mean by this that it's no longer energy, but merely that it's no longer in the right form to be used electrically. In contrast, electrical energy which has been "locked up" by a change of phase relationships in an ac signal is not used up, because we can easily get to it again by changing the phase relationships back again.

When we do anything at all to electrical energy by means of our circuits, we must "use up" at least a part of that energy. Some of the energy we "use up" is wasted – that is, it doesn't do anything effective for us. If the circuit is operating properly, though, most of the energy "used up" will be used in doing what we want the circuit to do.

For example, the whole purpose of a radio transmitter is to transmit information to one or more other locations by radiating radio energy from the antenna. The energy which we radiate is "used up" so far as the transmitter is concerned; we don't get it back to use again, but must continue to supply more energy in the form of the operating voltages which keep the rig going.

Whenever we use up energy in this manner, it's convenient to be able to determine how much we are using at any specific time, as well as to know how much we have used since we began to use it.

Now we get back to our immediate subject, power. "Power," as it applies to electricity, is simply the rate at which electrical energy is used. This is *not* the same as the amount of energy used, any more than "miles per hour" is the same as "distance." The power measures only the *rate* of energy use.

Back in the first chapter, we learned that voltage is a measure of electrical pressure or potential, while "charge" is a measure of the actual amount of energy at any instant. "Current" is a measure of the *rate* of "charge," and so "power," which is the rate of energy usage, must be related to both "voltage" and "current."

And the formula for determining power is simple: power equals voltage times current. If potential is in volts and current is

in amperes, the resulting power will be in the unit of power, "watts" (for James Watt, inventor of the steam engine).

In physics, of which electronics is a branch, "power" is the same kind of thing as "work," and conversion factors exist which enable us to convert units of power into units of work. For instance, 746 watts equals 1 horsepower.

Notice that because power is a measurement of rate, like "miles per hour," rather than an absolute measurement such as "distance," it tells us nothing about the *total* amount of energy used. Just as the question "Which goes farther, a bicycle moving at 10 mph or an airplane doing 500 mph?" cannot be answered until the time of travel of each is known (if the bicycle goes for 72 hours while the airplane goes for only half an hour, the bicycle will go nearly three times as far), neither can the question "Which uses more energy, a 5W transmitter or a 50 kW transmitter?" be answered until the time during which each is operated is known. The 5W transmitter must operate 10,000 times as long as the 50 kW one to use the same amount of energy – but if it operates more than 10,000 times as long, it will use more!

To measure total energy consumption, we use such units as the kilowatt-hour or the watt-second. One kilowatt-hour is the amount of energy used by a 1 kW device in one hour, or a 1W device in 1000 hours, or any other combination which multiplies out the same way when power in kilowatts (thousands of watts) is multiplied by time in hours. Similarly, a watt-second is the amount of energy used by a 1W load in one second, or simply power in watts multiplied by time in seconds. The watt-second is also known as the "joule," after the physicist who first stated many of the fundamental ideas about energy and power, and is the standard unit of electrical energy usage. In practice, power companies charge for their product by the kilowatt-hour while photographers rate their strobe-light energy storage capabilities in watt-seconds or joules, and radio operators seldom worry about either since they are more concerned with the rate of energy use than with the total amount used.

How is Power Measured?

We've just met one way in which power is measured – in "watts." And we have learned that 1W is the rate at which energy is used in a circuit which operates at a potential of 1V and requires an energy flow of 1A. We also met the "kilowatt," which is 1000W. Now let's look at some of the other measurements of power.

Suppose for a start that we wanted to know how much power was required by a circuit operating at 100V dc, but that for some reason we had no ammeter with which to measure its current. We do know, however, that its resistance is 250Ω.

We can apply Ohm's Law using the known values of voltage and resistance to determine how much current flows. This tells us that current equals voltage divided by resistance, so we know that the current is 100/250 or 0.4A.

We can then plug this 0.4A figure into the power equation $P = EI$ to get power as 100V times 0.4A, or 40W.

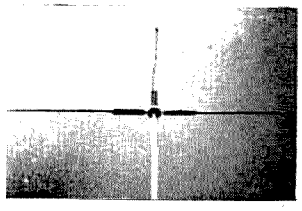
For a shortcut, we can combine the equation of Ohm's Law that tells us $I = E/R$ with the power equation $P = EI$ by substituting the entire right-hand half of the Ohm's Law equation into the power formula in place of the I. This gives us a new power formula, $P = EE/R$. Since E times E is usually written as "E squared" (E^2), this gives us $P = E^2/R$, which defines power in watts as the square of the applied voltage, divided by the circuit resistance.

The same thing can be done if we know current and resistance but do not know voltage. In this case, we use Ohm's Law to determine voltage ($E = IR$) and substitute the "IR" from that equation in place of the "E" in the power formula to get $P = IIR$, or $P = I^2R$. That is, power dissipation in a circuit is equal to the square of the current, multiplied by the resistance.

The relation between power dissipation, current flow, and resistance which we have just developed is extremely important throughout electricity and electronics. It's the reason, for instance, that the power distribution circuits which carry ac power around the country from generating plants to the ultimate users operate at such high voltages. By using high voltage, current can

be kept comparatively low while transmitting the same amount of power. Keeping current low reduces the I^2R loss in the power lines, so more of the energy gets to the ultimate user and less goes to provide a foot-warmer for stray birds.

It's also the reason why a high-Q tank circuit in a ham transmitter may get hot enough to melt its plastic coil supports, even when there's apparently very little power going anywhere. A tank circuit with high Q has high circulating current, which may be measured in the hundreds of amperes, and the wire of the coil has a definite minimum resistance. If circulating current is 100 amperes and coil wire resistance is only 0.01 ohm, the I^2R power dissipated in the wire is still 100 x 100 x 0.01 or 100W. And a hundred watts worth of heat is quite a bit; if you don't think so, touch a 100W light bulb after it's been on for an hour, or maybe the tip of a 100W soldering iron.



The three major ways of determining power in watts, then, are by multiplying voltage and current ($P = EI$), by relating voltage and resistance ($P = E^2/R$), and by relating current and resistance ($P = I^2R$). These equations, like Ohm's Law, work for all dc circuits, and for resistive ac circuits with certain restrictions.

The major restriction upon use of these equations with ac circuits involves the *units* of measurement to be used. With dc, a watt equals the power of a volt at a current of one ampere. When ac is introduced, the "voltage" and current are always changing – and this means that the "watt" becomes open to confusion unless we restrict things.

Even if we follow the conventional engineering standard and ignore all ac except the kind which has a sine waveform, both the current and the voltage are continually varying from a negative peak value through zero to a positive peak value and back again. To get a "power" calculation, we must choose which of these unlimited voltage and current levels to use.

While we might at first be tempted to use the "peak" levels, if we did we would find that "volts times amperes" would give us a figure that represented more power

UNIVERSAL ANTENNA BRACKET-MOUNT

Rugged, corrosion resistant aluminum casting, with four ⅜-24 studs, for 1¼" tube-mast mounting.

Accommodates up to 4 extra loading coils with Hustler 4-BTV trap vertical, for expanded bandwidth up to 240 KHz on 75/80 meters. (See article "Two on Top" by W6AJZ, 73 Magazine, May 1969.) Or use to build your own 5-band vertical antenna (Article "1-2-3-4 On a Mast" by W6IEL, Popular Electronics, August 1970).

Excellent foundation for Ham and CB ground plane radials, or "spider" for mounting spreaders on small cubical quads.

Only $7.95 postpaid anywhere in U.S. or Canada. Send postcard for detailed information, or order direct from —

KW BALUN KIT STILL ONLY $5!

The AMIDON Toroid Balun Kit makes a modern, compact antenna transformer that can be wired for either 4:1 or 1:1 impedance ratio. The balun is ideal for use between a coaxial feedline and a balanced antenna. It reduces coax radiation and properly balances the energy for application to the antenna's feedpoint. The balun also acts as an isolation device and removes the capacity of the coax from the antenna which extends the low SWR frequency range of the array. Baluns made from this kit can be used to advantage on these antenna types: Dipole, Quad, Beam, Inverted Vee, Windom and Folded Dipole.

than "volts times amperes" in a dc circuit does. In fact, the figure would be just twice as great as in a dc circuit.

This, of course, is not a happy state of affairs. A watt should be a watt, regardless of whether it's dissipated in ac or dc circuits.

If, instead of the "peak" levels, we use levels which will produce a "watts" figure just half as large, everything will come out as it should. But we cannot do this by using half the peak voltage and half the peak current, for that would give us half of a half, or one fourth, the power.

What we have to do is find a voltage level and a current level which multiply out properly. If we divide the peak value in each case by the square root of two, we will have such levels.

What's more, these levels turn out to be the "rms" or "effective" levels we have already met. In fact, the "rms" levels were chosen as the "normal" values for ac voltage and current specifically because they do provide power figures which are equal to those obtained with dc. Whenever ac power is mentioned, unless it's qualified with some sort of modifying word, what is meant is the power determined by multiplying rms voltage by rms current.

Another restriction on the determination of power in ac circuits comes from the fact that power can only be dissipated when voltage and current are in phase. That is, nothing but *resistance* can dissipate power. Ac circuits, however, normally contain reactance as well.

Reactance acts just as does resistance to limit voltage or current in the circuit – but this control is not achieved by dissipating the power into heat energy. Instead, the phase is altered. Since no power is dissipated by doing this, the effect cannot be expressed in "watts" or any other unit of power.

To cover such situations, the unit known as the "voltampere" was invented. Like power, it's obtained by multiplying rms volts times rms amperes, but it doesn't necessarily indicate any use of energy. If the circuit is composed of resistance only, its "voltampere" figure will be the same as its "power" figure; if reactance is present, there will be more "voltamperes" than "watts," and the difference between them indicates the amount of reactance. The ratio of "voltamperes" to "power" is known as the "power factor," and you may see it in the ratings for transformers or electric motors.

Now that we've seen how ac power is calculated and why the rms values of voltage and current are used, let's look at some of the modifiers often attached to the phrase – for instance, "average power."

This is a term most frequently used with respect to the power of an amplitude-modulated radio signal, and has nothing to do with "average voltage" or "average current." Instead, it's the average of the signal's rms power level, taken over several cycles of the modulating signal.

For this to make any sense, we must jump a little ahead of ourselves at this point and take a quick look at amplitude modulation (more exact discussions of modulation will come quite a bit later in this course). Figure 1 shows the

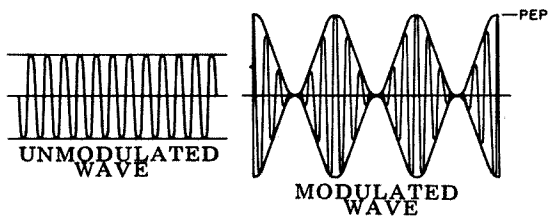

Fig. 1 Waveforms of unmodulated or "carrier" signal, and complete modulation envelope for 100% amplitude modulation are necessary to illustrate some of the various power measurements often encountered.Peak envelope power, for instance, is the power calculated from voltage and current at modulation peak, as indicated at right.

"envelope" waveforms of both a modulated and an unmodulated AM signal. You can see that the modulated waveform rises to higher peaks than does the unmodulated or "carrier" signal.

If the modulating signal is a sine wave, and if the maximum amount of modulation is applied as it is in Fig. 1, the total power of the modulated signal (averaged over several cycles of modulation) will be half again larger than that of the carrier. The "average power", then is 1.5 times

greater with such modulation than without.

"Instantaneous power," on the other hand, refers to the power figure that results from taking one specific instant during a cycle and multiplying the voltage at that instant by the current at the same instant. These are *not* rms values – the "instantaneous" values are used instead. If we choose the instant when both voltage and current are peak, the "instantaneous power" comes out to twice the "average power" – and in the modulated signal with its higher peaks, the maximum "instantaneous power" is four times as great as the carrier's "average power."

The maximum "instantaneous power" level possible for a modulated signal – that is, the instantaneous power at the peak of the modulation cycle – is called the "peak envelope power" or "PEP." This figure is often used to rate output power of SSB transmitters, and to compare the power levels of various types of modulation.

We have just noted that the average power of a fully modulated signal (if the modulation is itself a sine wave) is 1.5 times that of the carrier alone. The "extra" power is contained in the sidebands which are produced by modulation, and so is known as "sideband power." From this, we can say that "average power" of a modulated signal of any kind is equal to the "carrier power" plus the "sideband power."

"Audio power" is that power at audio frequency which furnishes, either directly or indirectly, the sideband power. If plate modulation is used, audio power and sideband power will be approximately the same number of watts (the only difference is that caused by the fact that the modulation process cannot be 100% efficient). The difference between the two in this case is that "audio power" exists as an af signal, while "sideband power" is at radio frequency.

All of these various kinds of power are related directly to the voltage and current which produce them, and all except instantaneous power and PEP are the product of rms voltage times rms current. Their relation to the "carrier" power level varies with the waveform of the modulating signal and the particular kind of modulation technique employed, and we'll go into that more deeply when we get to modulation.

When we attempt to measure the power involved in an ac signal which is *not* a sine wave, we have a problem. While it's theoretically possible (as we shall soon see) to analyze *any* ac waveform into a combination of sine waves, this is not a practical approach to power measurements.

The most accurate way to measure the power content of a non-sine-wave ac signal is to dissipate the power into heat by means of a suitable resistor, and use a thermometer to measure how much heat it produces. From this, we can determine the power figure by converting degrees-of-heat-rise to calories, and calories to watts.

Such an instrument is known as a "bolometer," and is often used in microwave work to measure the power of pulsed signals.

If the departure from a sine waveform is not extreme, many persons simply calculate peak instantaneous power from the voltages and currents as displayed on a scope, and divide that by two to get approximate rms power. Accuracy of this method depends on just how close to a sine wave the signal happens to be. For voice signals, it's not too accurate – but the error is such as to make you believe you have more power than is really present, so it turns out to be simply a safety factor in practice.

What is a Decibel?

Contrary to what you may believe or have heard, the decibel (abbreviated "dB" and often pronounced "dee bee") was *not* invented solely for the purpose of making an already complex situation more confusing. In fact, the whole idea behind the decibel was to make things simpler!

And once decibels are adequately understood, they do simplify matters. The problem is like that of making friends with a porcupine; no matter which direction you approach from, it's only too easy to get stabbed unexpectedly by something painful.

Most textbooks approach decibels from a mathematical viewpoint, which isn't such a bad idea, except that you don't really have to comprehend the math behind them in order to make good use of them. We'll try another approach.

In many situations involving a comparison between two values of the same quantity – such as the amount of light present in a room, or the intensity of sound produced by a PA system – it's not so much the *absolute* difference between the values that's important, as the *ratio* between them.

That is, you wouldn't compare the brightness of two different light bulbs by saying that one was "25 watts more powerful" than the other. Instead, you would say that it was "twice as bright."

If one bulb was a 25-watter and the other rated at 50 watts, you might expect twice the brightness from the doubling of power, but you wouldn't expect to keep getting twice the brightness every time you went up another 25W in power.

Actually, the relation between brightness and wattage of the bulb isn't really all that simple and we don't mean to imply that it is. Our purpose is to bring out the difference between the *ratio* of "twice" or "double," and the *absolute* increase of 25W.

Musical tones offer another example. On most pianos, the note known as "middle C" has a frequency of approximately 512 Hz. The next higher C is about 1024 Hz, and the C above that is about 2048 Hz. The absolute values determine whether the tone is at the top or bottom of the keyboard's range, but the 2-to-1 ratio is what makes it a C rather than a B or a D.

Now we bring decibels back into the picture. All that the decibel amounts to is a unit for the measurement of power *ratio* rather than any absolute value. Any time power is doubled, it has been increased by 3 dB, no matter what the starting point. If the power is cut in half, it has been decreased by 3 dB.

While the decibel is the unit normally used in all technical work, it is not the "basic" unit. The basic unit of power ratio is the "bel," named for Alexander Graham Bell of AT&T renown, and it's defined as being a power ratio of 10:1. The "decibel" is one-tenth of a "bel" – but it's not a 1:1 ratio (the 1:1 ratio is zero bels or 0 dB). And right here is one of those porcupine quills.

The problem is that *ratio* itself involves multiplication or division. A 2:1 ratio implies multiplication or division by 2, a 10:1 ratio by 10, and so forth. The *units* of ratio, though, are not multiplied or divided, but instead are added or subtracted. a 10:1 ratio is 10 dB. A 100:1 ratio is not 10 *times* 10 dB or 100 dB, but rather is 10 *plus* 10 dB or 20 dB.

If you're familiar with the mathematics of a log table or of exponents, you have probably realized by this point that the decibel behaves like the log of the true ratio. The bel, in fact, *is* the log of the power ratio, and since 10 dB equals 1 bel, the formula for calculating decibels becomes merely "10 times the log of the power ratio." If you have a log table handy, the ratio itself can be calculated by logs – but that's not required in order to make use of decibels, as we shall see shortly.

Strictly speaking, the bel and decibel are units for the measurement of *power* ratios and cannot be used for measuring anything else. This might appear to be rather confining until you recall that power is simply a measurement of the rate at which energy is used, so that whenever energy is actually being dissipated you have power whether you realize it or not.

The situation isn't helped any, though, by the fact that many people speak (incorrectly, as it happens) of "voltage decibels" and "current decibels."

These "voltage" and "current" decibels came into vogue because it's possible to calculate power when only voltage or current, and circuit resistance, are known. We saw this in the previous section of this installment, and developed a pair of "shortcut" equations by combining the power formula with the appropriate form of Ohm's Law.

Since decibels are calculated by first getting the ratio between two power figures, then taking the log of that ratio

and multiplying by 10, it's possible to plug the "shortcut" power equations in place of the actual power figures, and come up with a corresponding pair of decibel equations which apparently compare voltages or currents. Both the shortcut power equations involve squaring the voltage or current figure, and when we move this into the decibel equation we do the squaring by multiplying by 20 rather than 10.

But what we have is still a *power* ratio, and in addition we have introduced a restriction that both voltage figures (or current) must be in circuits of identical resistance.

Since a 2:1 power ratio comes out to 3 dB and a 2:1 voltage ratio comes out as a 6 dB, people began calling the decibel values obtained from the composite equations "voltage" or "current" decibels and the belief grew that they were somehow different from "power" dB.

Actually, there's no difference between one set of dB and any other. The apparent difference is actually the difference between a power ratio and a voltage ratio.

If we double the voltage present across a resistor without changing the resistance value, the current through it must also double (Ohm's Law proves this). That means that when we figure the power, we must multiply twice the voltage times twice the current, and we come out with a power ratio of 4:1.

A power ratio of 4:1 comes out to be 6 dB, and a voltage ratio of 2:1 is also 6 dB. Since a 2:1 voltage ratio across the same resistance (which you recall is a requirement for using the "voltage decibel" equation) is the same as a 4:1 power ratio, you can see that there's no difference in the decibels themselves whether we get them by voltage/current calculations, or by power calculations.

If you're going to use log tables to deal with decibels, here are the two equations:

$$\text{decibels} = 10(\log \text{power}_1 - \log \text{power}_2)$$

$$\text{decibels} = 20(\log \text{voltage}_1 - \log \text{voltage}_2)$$

For current, use the "voltage" equation but substitute current in place of voltage. For either equation, the larger of the two quantities is always used as the first, so that the result will always be positive.

But you don't need to use a log table or a slide rule – or even know what they're all about – to figure out decibels accurately enough for all practical purposes. All you need to do is memorize a couple of facts and four specific decibel values.

We've already met the facts – they are that decibels add together, so that if you know a 10:1 ratio is 10 dB, you can figure out a 100:1 ratio as being 20 dB and 30 dB as being 1000:1. The process can continue as long as need be. Adding dB multiplies the ratio, and subtracting dB devides the ratio. If 100:1 is 20 dB and 2:1 is 3 dB, then 50:1 is 20–3 or 17 dB.

Now for the values. One decibel is 1.25:1, or 5:4. Three dB is 2:1; 5 dB is 3.16:1, and 10 dB is 10:1. From these, we can get any other values we may need by adding and subtracting. For instance, 9 dB is 3+3+3 dB, or 2x2x2 or 8:1.

From just these values, you can find out how many decibels any specific ratio amounts to, or conversely what ratio is meant if you have a known number of decibels, because you can build up any number you want by proper addition or subtraction of 1, 3, 5, and 10.

For instance, how many decibels stronger than a 25W transmitter is a 500W one? First, we convert the absolute power figures of 500W and 25W to a ratio by dividing 500 by 25, and discover that the ratio is 20:1. Next, we divide the 20 by 10 and note down the 10 dB effect of that division; the resulting ratio is 2:1. But a 2:1 ratio is 3 dB, so we add 3 dB to the 10 we already have, and the answer is 13 dB.

Let's try another one. Good operating practice requires that all spurious products from a single sideband transmitter be at least 35 dB below the power level of the transmitted sideband output. If we have an SSB rig with a PEP of 150W, how much power can we let out as "garbage" without violating these standards?

This time, let's take care of the odd 5 dB first. To do so, we divide our 150W PEP figure by the 5 dB ratio equivalent, 3.16, and come up with about 47.4W. This would be 5 dB below the PEP, but we want to be 35 dB below, so we still have 30 dB to go. But 30 dB is a 1000:1 ratio, so

dividing 47.4W by 1000 gives us the answer – 0.0474W, or a little less than 50 mW PEP of garbage would be permissible.

With this technique, you don't need a log table or a slide rule to be a decibel expert – and comparison of power levels is as simple as adding and subtracting.

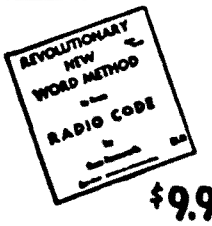
One point deserves special mention here; the S-meters on many receivers are calibrated in both "S-units" and "decibels over S9," and most operators believe an "S-unit" equals 6 dB.

Actually, however, the "dB" indicated on S-meters bear little if any resemblance to true decibels. We'll prove it:

Most S-meters will indicate a signal that is supposed to be "60 dB over S9." That means a signal having one million times the power of one which produces an S9 reading, which would require one thousand times the voltage of an S9 signal at the receiver input terminals.

Most S-meters, also, are calibrated to read "S9" at an input signal level of 25, 50, or 100 mV.

That means the "60 over 9" signal, if it really *were* 60 dB over S9, would be at least 25V at the receiver input. If the antenna is connected to the receiver via 52Ω coax, that 25V level would amount to about 12W of rf power coming into the receiver. Many transmitters which won't put out 12W to their own antennas, however, will produce solid "60 over 9" signals on receivers several miles distant! If the S-meters were anything like accurate, this would mean that the signal had to *gain* power between the transmitter and the antenna – but in fact it loses power rather rapidly.



Had enough of decibels for now? Let's move on to another subject which also deals with ratio – but ratio of "frequency" rather than of "power" or "energy."

What Are Harmonics?

Back in the first chapter of this course we made the acquaintance of ac, and met one of the major characteristics of any ac signal – its frequency.

An ac signal may have any frequency greater than zero, although most common ac signals lie in the range from around 10

JOHN SAYS "GLOBE PLOTTER" WORKS LIKE MAGIC

Picture yourself in your car on a very dark night, with a two-cell broad beam flashlight, looking for a house number. O.K.? Sorry, but all you can see is the house and a vague shadow where the house number is located. You can't read the numbers. Let's say you can adjust that flashlight to a very narrow beam of light. "Presto!" – like magic, you can see the numbers now as though it were daylight. Our GLOBE PLOTTER will do the very same thing for you with your present "beam" if it has a rotator. Picture this in your mind. The GLOBE PLOTTER is a beautifully colored six-inch-in-diameter globe of the world. It rests on three sturdy round pegs, embedded in a round rotating base which is calibrated in degrees from 0° to 360°. Down the front of the globe from the top to the bottom is a sturdy wire which follows the front contour of the globe only a fraction of an inch from the surface. To operate the GLOBE PLOTTER, rotate the disc and globe with your thumb and forefinger until the desired QTH falls directly under the wire indicator. Read off in degrees, and with your other hand press the lever on your rotator to the exact degree setting. This is all done in five seconds or less. You will be talking to the other station before the gang can figure out where to set their beam. It's not only a great breakthrough in direction finding, but it's also beautiful. Don't let the price fool you! It's priced low to sell, and you will have to agree it's worth double the price. $17.95 plus postage and handling today with your money order, and your GLOBE PLOTTER will be sent to you promptly. Do it today – you will be glad you did. TESTIMONIAL BY JOHN T. CANTRELL KØGVK

or 15 Hz up to several thousand MHz. Physicists consider light itself as an ac signal of exceptionally high frequency (so high, in fact, that it's not normally measured in hertz at all), and for some purposes it turns out to be convenient to treat dc as being an ac signal with a frequency of zero.

Since an ac signal may have any frequency at all within this unimaginably wide range, it's only natural that some signals must have frequencies which are exact multiples of those of other signals. For instance, a 24 Hz signal is at two times the frequency of a 12 Hz one, or 3 times that of an 8 Hz signal, or 4 times a 6 Hz signal, and so forth.

We can go the other way, too. For instance, if we start with an 8 Hz signal, we could have signals at 2 times 8 or 16 Hz, 3 times 8 or 24, and so forth all the way up until we run out of numbers.

The point is that no matter what the frequency of the signal with which we start, other signals may exist at frequencies which are exact multiples of our original. As it happens, these other signals bear some special relationships to our original signal, and for this reason are known as the "harmonics" of the original (which is itself known as the "fundamental frequency" signal or merely "the fundamental").

One of the special relationships between a fundamental and its harmonics involves their mutual timing. If we start all the signals from zero at the same instant, then whenever the fundamental's voltage (or current) waveform crosses zero, so will that of each harmonic.

This is always true, because of the definition of a harmonic as "an exact multiple" of the fundamental frequency. If the frequency is two times that of the fundamental, then during the time that the fundamental goes through one half of its cycle and gets back to zero, the harmonic will complete a full cycle and reach zero at the same instant. When the fundamental has completed one full cycle, the harmonic has completed two, and again they reach zero together. The harmonic also goes through zero when the fundamental is at either peak – but we don't care about that right now.

If the harmonic frequency is three times that of the fundamental rather than twice, then when the fundamental is half-way through its cycle and reaches zero, the harmonic will have completed one full cycle and will be half-way through another one. At the end of a full cycle of the fundamental, the harmonic will have completed three cycles.

Harmonics are identified as second, third, and so forth, according to the multiplying factor involved. The second harmonic is at a frequency two times that of the fundamental, the third at three times fundamental frequency, and so on. The "order" of a harmonic usually refers to its separation from the fundamental; second, third, and fourth harmonics are often called "low-order," while fifth and higher are known as "high-order." The dividing line between "low" and "high" harmonics, though, depends largely on the particular problem under discussion.

The same arguments which we just applied to the second and third harmonics apply to all of higher order as well. Those which are at even multiples (even harmonics) of the fundamental will be completing a cycle when the fundamental reaches the midpoint of its cycle, and odd harmonics (those at odd-numbered multiples) will be in the middle of a cycle when the fundamental is at midpoint.

Because the timing relationship between a signal and its harmonics is made constant in this manner by the definition of harmonic, we can talk about "relative phase" between a signal and its harmonics although in general, "phase" and refer only to timing differences between two signals of identical frequency.

That is, an odd harmonic which is "in phase" with its fundamental crosses zero at the same time as the fundamental, and is going in the same direction (whether positive or negative).

The same signal "180 degrees out of phase" with its fundamental will still cross zero at the same instant as the fundamental every time, but will be always going toward opposite polarity.

If the two are "90 degrees out of phase" with each other, the harmonic will be at a peak value whenever the fundamental crosses zero. (See Fig. 2 for an illustration of these phase relationships between a signal and its third harmonic.)

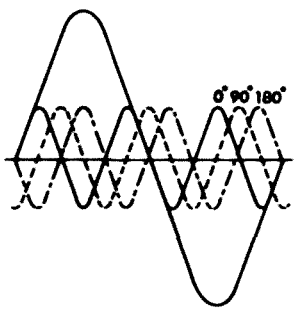

Fig. 2. Phase relationships between fundamental and odd harmonics are illustrated here using third harmonic. At 0 degrees, or in-phase condition, harmonic and fundamental both cross zero line at same time going in same direction. At 180 degrees, or opposite-phase condition, they cross in opposite directions. The 90-degree phase relationship is midway between these (dotted line).

The exact description of phase relationships between a signal and its harmonics depends to a large degree upon the order of the harmonic. Whether an even harmonic is "in phase" or "180 degrees out of phase" depends upon which half-cycle of fundamental you start from, as shown in Fig. 3 for the second harmonic.

Another special relationship between a signal and its harmonics involves the way in which they combine to produce signals which are not sine waves at all. Take, for example, a combination of fundamental and third harmonic such as that shown in Fig. 4.

When both these signals are present in a circuit which permits them to combine, the net energy at each instant is the total of the energy in both signals. At certain moments they add together, and at others they cancel; the result is the waveform shown by the heavy line in Fig. 4.

If we change the phase relationship between the two signals, the waveform changes, because the addition or cancellation occurs at different times.

Similarly, if we introduce still more harmonics into the mixture, we can produce far different waveforms.

When enough different harmonics are present, and with the phase of each being independent of all the rest, we can reproduce any ac signal at all. This is another reason why engineers deal only in sine waves although sine waveforms are rare in nature; any other signal may be treated as merely a combination of sine waves, each of appropriate phase and strength.

Even such decidedly non-sine waveforms as the square wave (Fig. 5C) can be built up from sine waves. Figure 4 showed the result of combining a fundamental and its third harmonic. Figure 5A shows what happens to this when the proper proportion of fifth harmonic is added, and Fig. 5B shows what happens when the first 100 odd harmonics are included; it's difficult to distinguish between the waveforms of Fig. 5B and Fig. 5C.

So now we have met the family of harmonics, and have seen that they are essential to most types of actual ac signals. Yet most discussion of harmonics centers upon methods of suppressing them, or preventing them in the first place. Why?

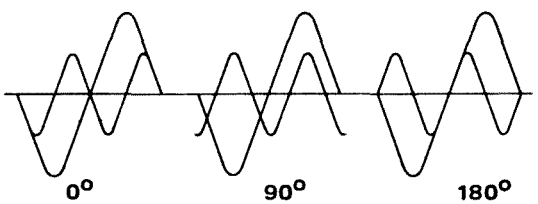

Fig. 3. Phase relation between fundamental and even harmonics (second is shown here) is a bit more confusing, since both the 0- (in-phase) and 180-degree relationships appear very similar.

A harmonic is good only if you want it. Like anything else, an unwanted harmonic or one which you cannot control is to be avoided whenever possible. FCC regulations prohibit transmission of excessive amounts of harmonic energy, and almost anything you can detect is considered to be "excessive." Yet we do make extensive use of harmonics in ham transmitters – always attempting to keep them under control.

Harmonics may be generated either deliberately or by accident, whenever a sine-wave signal is distorted by any means. If the signal was sine to begin with, and is not now, something must have been either added or taken away to make it different.

As it turns out, what was added was harmonic energy.

The distortion need not occur in an amplifier. *Any* action which distorts the signal will suffice. Most harmonic generation in ham transmitters, though, occurs in the amplifiers, because the "normal" rf power amplifier circuit distorts the signal greatly in the interests of handling high power with comparatively small tubes.

This distortion generates myriads of harmonics, because the waveform is very close to a square wave. All of them must be controlled. How to do so? That's our next subject.

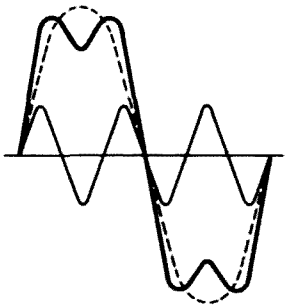

Fig. 4. Sine waves can be combined to produce any ac waveform. Combination of fundamental and third harmonic, shown here, produces tooth-shaped waveform (heavy line) which is first step toward square wave.

How Can Harmonics Be Controlled?

Now that we have met harmonics, and have seen that the only bad harmonic is one which we do not control, we're ready to try to find ways to control them effectively.

In general, harmonics can be controlled by either or both of two major routes. The first concentrates upon preventing their existence, while the second places the emphasis upon containing them so that they cannot escape.

Most practical situations require both types of control. The first, alone, is impractical and probably impossible as well, because all the efficient rf amplifier circuits capable of handling high power also generate harmonics prolifically. Without the first, the second becomes an unimaginably large job.

Both together, though, hold down the strength of the harmonics which are generated, and make them easier to bottle up.

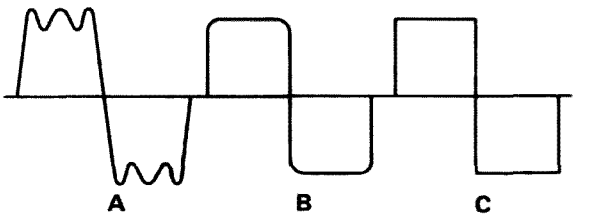

Fig. 5. Square wave can be considered as sine wave together with all its odd harmonics in proper proportions. At left (A) is result when fundamental, third, and fifth harmonics are mixed. Center (B) shows waveform when first 100 odd harmonics are included. Idealized square wave (C) is difficult to distinguish from version produced by first 100 odd harmonics; few scopes would be capable of telling which is which.

To find out how to keep harmonics from coming into existence, let's turn things around and see what we do to encourage harmonics whenever we deliberately want them (because most transmitters do make deliberate use of harmonics, in order to get improved frequency stability).

Deliberate harmonic generation is usually accomplished by circuits known as "frequency multipliers," which look like any other rf amplifiers so far as the schematics are concerned. What makes one generate harmonics for us is the specific manner in which it is operated.

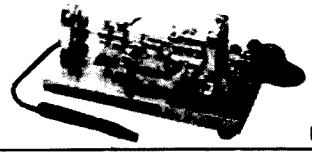
To get a good harmonic generator, we bias the tube's grid much more strongly than for normal amplification, so that its switching action becomes more abrupt; then we apply much more driving power than normal to the stage, again to make the switching as rapid as possible and the output waveform as close to square as we can get.

When we do this, the tube's output signal has a high percentage of harmonic energy, and it's a simple matter to pick off the one we want with a selective (high-Q) resonant circuit. Usually, we take either the second or the third, because it's difficult to get enough power at higher multiples in a single stage. VHF transmitters often use an 8.3 MHz crystal followed by a tripler to 25 MHz and a doubler to 50 MHz, before beginning real power amplification.

Now if we want to generate as *few* harmonics as possible, all we need do is

reverse this philosophy. We take special care to bias the tube only enough to get the job done, and to keep driving power at the lowest level capable of producing proper output. The output will then be as free of harmonics as we can get – but they're still present, so our job is not yet done.

If we increase the Q of our resonant output circuit, we will make it more selective and it can reject the harmonics more efficiently. This will reduce the harmonic level at the antenna. In an rf circuit, we can raise Q by increasing the capacitance and then reducing inductance to keep the circuit resonant. Most of the effective resistance of the circuit is in the coil, and so when we reduce inductance we reduce resistance as well. The resistance decreases more rapidly than the reactance, and Q goes up accordingly.



When we have reduced harmonics to the practical minimum by applying these ideas to all straight-through (input and output at same frequency) amplifier stages in a transmitter, we have almost exhausted the possibilities of the first method of harmonic control and it's time to turn our attention to the second – that of bottling up the remaining harmonic energy so that it cannot escape to cause trouble elsewhere.

Before we do so, though, one point needs special emphasis and a couple of tricks with harmonic generators deserve mention.

The point which we must emphasize is that a harmonic cannot be *generated* by anything which does not introduce distortion into the signal, but that the *radiation* of a harmonic can be suppressed by non-distorting devices.

In particular, neither a feedline nor an antenna can generate harmonics if it is in decent working condition; about the only thing in either which could *generate* a harmonic would be a corroded connection. However, if a harmonic is generated back in the transmitter, the feedline and the antenna can easily radiate it to the world – or just as easily can help you keep it contained.

Now for the harmonic-generator tricks. When we use a harmonic generator to double or triple a frequency, we want a single specific harmonic and we don't want any others if we can help it.

As it happens, there's a special type of circuit which can generate even harmonics but suppresses odd ones, and another circuit which generates odd harmonics and cancels out the even ones. Use of these circuits makes life much easier, because the selectivity of the output circuits doesn't have to do so much of the selection job.

The even-harmonic generator is usually called a "push-push" doubler and the schematic appears as Fig. 6. Here's how it works:

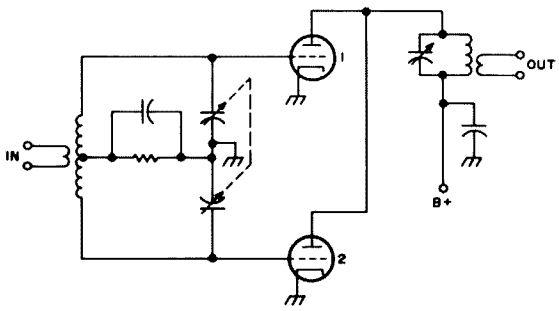

Fig. 6. This circuit, known as "push-push" multiplier, generates only even harmonics of input signal and cancels out fundamental and all odd harmonics.

The centertapped grid circuit divides the input signal into two independent signals, identical in strength but opposite in phase, and applies each to its own amplifier tube. Operating conditions for both amplifier tubes are made identical by the common grid resistance. Outputs at the plates of these tubes will be 180 degrees out of phase with each other at fundamental frequency, but the bias is chosen so that each output also contains an appreciable amount of second-harmonic energy.

These second-harmonic signals are in phase with each other (Fig. 7) despite the out-of-phase condition of the two halves of the fundamental signal.

When both plates are connected, in parallel, to the same tuned circuit, the fundamental portion of the output signal cancels itself out. No such cancellation occurs, however, for the second (or any

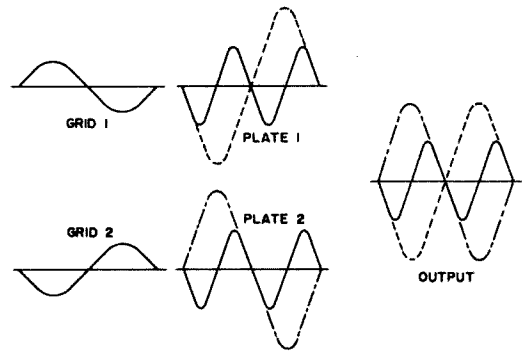

Fig. 7. Input and output waveforms show how push-push doubler works. Grid waveforms, at fundamental frequency, are equal in strength but opposite in phase. Same waveform, only amplified and reversed in phase, appears at plates of tubes – together with second-harmonic component introduced by tube's operating conditions. In output circuit, the two fundamental waveforms cancel each other out, leaving only the second harmonic.

even) harmonic, so by tuning the output circuit to the desired frequency we can recover the even-harmonic energy and couple it out to a later stage.

All odd harmonics are canceled, just as was the fundamental, because they are effectively 180 degrees out of phase with each other at the output.

If we want the odd rather than the even harmonics, a minor modification to the circuit as shown in Fig. 8 does the trick.

The input and amplification action is the same as in the "push-push" circuit. However, rather than the plates being connected in parallel, they are connected to the opposite ends of a "split" circuit which reverses the action of the input circuit, to combine the out-of-phase halves of the signal into a single, in-phase, output.

The recombination is accomplished by effectively reversing the phase of signals from one side, and leaving those from the other alone. This means that the previously in-phase even harmonics are now out of phase with each other, while the out-of-phase fundamental and odd harmonics are pulled into phase.

This circuit is known as the "push-pull" amplifier, because the phase relationships make it appear that half the circuit is "pushing" the signal while the other half is

"pulling" it and vice versa. It finds side use as a straight-through amplifier as well as a tripler, and always cancels out even harmonics without effect upon the odd harmonics or fundamental.

When we're trying to reduce harmonic generation to a minimum, use of either a push-push doubler or a push-pull tripler will help; either eliminates at least half the harmonics which might otherwise be generated in a frequency-multiplier stage.

Now let's move on to the other half of the harmonic-control situation and see how to bottle up or contain harmonics which we cannot avoid generating.

The starting point in containment of harmonics is to make it as difficult as possible for them to follow the normal signal-energy route. This means using enough tuned circuits in the normal path, and having adequate selectivity in each, so that harmonics will find it rough going.

To get selectivity we must have adequate "Q" in the resonant circuits. Attempting to get out the last particle of power by loading each stage to its limit or above is a sure way to reduce the Q of its tuned circuits, because Q is among other things a ratio of energy stored to energy released, and when we load a stage we force it to release energy. Harmonic output may skyrocket.

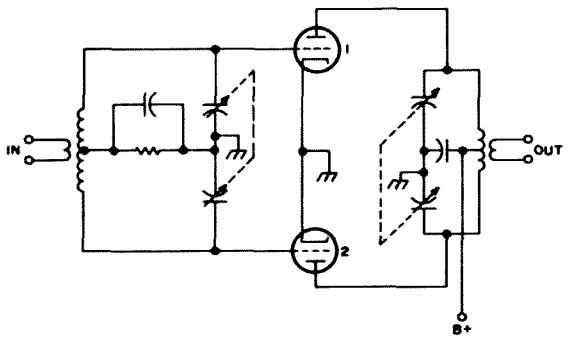

Fig. 8. Push-pull amplifier reverses action of push-push doubler to cancel out all even harmonics while amplifying fundamental or odd harmonics. If plate circuit is tuned to harmonic, it's a frequency multiplier, while if plate circuit is tuned to fundamental, it operates straight through.

Because tuned circuits cost money, and add additional controls which must be adjusted by the operator, many commercial rigs suffer a shortage of tuned circuits in the normal signal path.

We don't recommend redesigning equipment, but you don't have to. You can always add tuned circuits between the transmitter and the antenna by using an antenna tuner, despite the fact that many operators manage to radiate some sort of signal without one.

Another way of keeping down the harmonic output by containment is to be certain the feedline and antenna are well matched to each other, and that the feedline is properly grounded (if coax) or isolated (if open wire or twin lead) to prevent it from radiating on its own.

Proper antenna choice helps minimize harmonics. The popularity of "all-band" antennas helps us forget that any wire which works on 40 meters as well as it does on 80 cannot possibly help you reject the second harmonic of an 80-meter signal. Most "single band" antennas, on the other hand, have such high Q that they refuse to radiate signals at even harmonics of their band. They may perform nicely at odd harmonics, but the antenna tuner can easily take care of that by preventing the third harmonic from getting to the feedline.

When all these points have been covered, the only ways left for harmonic energy to get from the transmitter to the outside are by direct radiation from circuit components, and by conduction through wires which are not carrying the output signal (such as power leads, audio cables, etc.).

Direct radiation can be controlled by completely shielding the transmitter. If adequately done, this will make it impossible for rf to escape except by conduction on wires passing through the shield.

If we then add filters to each wire, to make certain that no energy travels in or on it except that which is supposed to be there, we can be fairly sure all harmonics are under control.

The filters may range from simple bypass capacitors on power lines, to complex arrangements of rf chokes, audio inductors, and capacitors, for lines which carry ac. Bypass capacitors often suffice.

WOW! AN/SSQ-23A Sonobuoy Only $14.95 Include $2.00 for postage and handling 20/2+2+2 = FN/FM

In fact, the normal legal requirements for control of harmonics are usually met without needing to shield and filter the equipment and its connections, but problems with television interference may make some shielding and filtering necessary.

We just mentioned filters – and that was getting ahead of ourselves by a fraction. In the next chapter, we'll go into filters and their action rather deeply, along with impedance matching and solid- state devices. . . . Staff ■

(Leaky Lines cont. from page 12)

ourselves out of business completely.

I want to tell you a little story. A very close and dear friend of mine owned a piece of property out on Long Island, and it had been in his family for generations. It was operated as a fish and game preserve where sportsmen could go and participate in their activities without any crowding or congestion. It was maintained by my friend through his own not inconsiderable resources, together with additional funds contributed by us, the others who used it. All of these were ardent conservationists, and all were fervent in their desire to preserve it and keep it from becoming just another fond, dead memory in a land in which such places are fast disappearing from the scene. All of us who used to wing shoot and angle there were quite convinced that we would succeed in protecting it from outside depredation. We felt that because we were doing what was clearly right, nobody would dream of changing things.

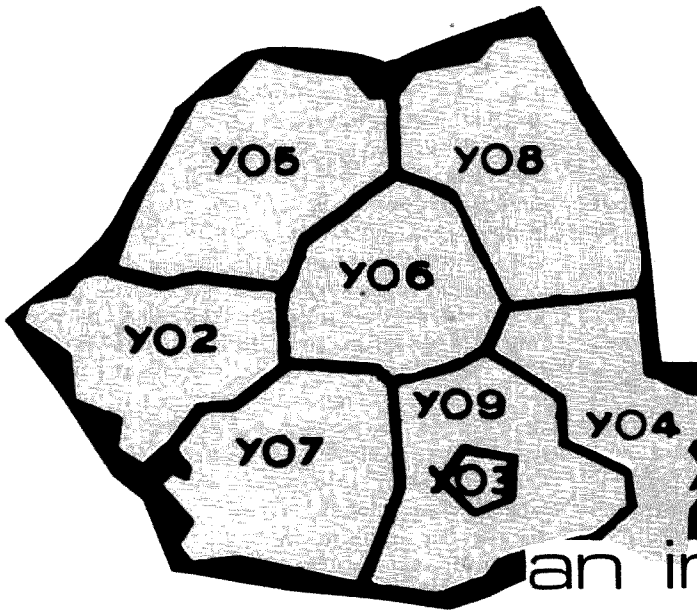
Then along came Mister Robert Moses, the former Parks Commissioner and high muckety-muck from New York City. He decided that this spot would make an ideal addition to the Parks System for the city. He filed for the property in the courts, and started official proceedings to take it over by what is called in law the "Right of Eminent Domain." My friend refused to sell, but in the end, he was literally forced to do so. Mr. Moses represented to the court that he needed to acquire it for the city so that it could be enjoyed by "all the people," instead of just an "aristocratic minority." And he succeeded in convincing the court that if private individuals were permitted to retain control, it would constitute a denial of the rights of the majority, and that this would be undemocratic. So, my friend was forced to relinguish ownership of a piece of prime land to the City of New York, and Mr. Moses lost no time in converting it to a recreational facility "for the people."

The duck blinds which used to line the river are now popcorn vendors, hotdog and pizza stands, and rest rooms. The herd of beautiful Japanese Sika deer has disappeared; so have the mallard, teal, and wood duck. The broad fields of millet and lespedeza which sheltered and fed pheasant and quail are now huge concrete and asphalt parking lots, where hundreds of cars and buses congest and pollute the air with their stinking exhaust fumes. The lovely little stream has literally become a cesspool, for those who bathe in it use it in precisely that fashion. The reverent silence which was unbroken save for the sounds of nature . . . birds, wind, rain, thunder . . . is now shattered by a maddening bedlam of transistor radios playing rock 'n roll, auto horns, screaming teenagers, loudmouthed and contemptuous misfits whose concept of the outdoors is concrete, steel, and glass. The grounds are strewn with fruit rinds, plastic containers, beer cans and bottles, discarded sundries made of liquid latex (the less said about which, the better.) In short, it

resembles the beach at Coney Island after a Fourth of July weekend. All in the name of "the people."

This happened because of one principal reason. The courts which swallowed Mr. Moses' grandiloquent plea in behalf of the "people" had absolutely no idea of the far deeper values of that place. They had never been shown. We all thought that they must surely understand the merits of our case by some natural instinct. We thought that anyone would tell the difference between right and wrong. We simply did not reckon with the awesome possibilities.

But nowadays, if Moses (or even Abraham or Isaac) were to try to pull a swindle like that, there would be an outraged outcry that would drown out the sound of Niagara. He would be swept away in the deluge of public indignation. Why? Because we have all been educated in the matter of pollution and conservation. Now we know that we must preserve the priceless heritage of our natural resources against those who seek constantly to exploit them for money, power, political gain, or even for the "people." There are far too many things in American life which have been utterly destroyed on the altar of forced collectivism, and if we are not alert to what is going on, we may find the same thing happening to amateur radio!



All the good intentions in the world cannot compensate for failure by default. Remember that old tale; For want of a nail the empire was lost? The feeble and impotent program of the League with respect to a real campaign of public relations is totally inadequate in representing and safeguarding the interests of almost 300,000 amateurs and the untold thousands yet to come. QST periodically (no pun intended) beats its tired tambourine about public relations. A photo is printed, showing one of our League functionaries posing with a mayor or chief of police or councilman, on the occasion of the unveiling of a bust of Guglielmo Marconi, or the first ham call license plates, or when some two meter hams coordinate the Split Lip, Kansas jug-blowing and Jew's harp tournament. Our activity is not a minor matter, to be treated like the grammar school spelling bee! Amateur radio is not a casual thing to be sloughed off so casually! Anyone who thinks it is, is just kidding himself. We have got to make sure that every legislator in this land is made familiar with the fuller and deeper significance of ham radio, than its use in controlling the floats in the Tournament of Roses, ski tournaments or boat regattas! We have got to make sure that the general public understands that in our ranks there reposes a nucleus of well-seasoned communications personnel, fully trained and equipped to assume vital obligations and duties, prepared to function in cases of national crisis and peril. We must educate Americans so that they will stop thinking of us (if they ever think of us at all) in terms of a bunch of hobbyists, playing around with toys and gadgets. We are not the same as model railroaders, antique collectors, mushroom pickers, bird watchers, weekend golf nuts, rug weavers, skin divers, folk singers, amateur plumbers, hikers or spelunkers! We are not scrabble players or spare time hypnotists and magicians. While we are certainly engaged in an activity which we enjoy, our interest is not a hobby! It is a *service!* And don't let anybody, but anybody, ever forget it!

The only way we can begin to do the job which needs doing, is to establish a properly functioning information office in Washington, D.C., with full-time people working at full time jobs, seeking influence in government circles, so that no one can throw a sneak punch while we're not looking. And make no mistake about it . . . there are many interests at this very moment, scheming and plotting, seeking ways in which to destroy our privilege, so they can get their hands on our frequencies, and use them for their own purposes. Any ham who feels secure about the amateur spectrum in today's dog-eat-dog world is either an ostrich or an imbecile! Any ham who would not be willing to bend all his energies and efforts toward insuring the future of amateur radio is either stupid or a scoundrel! And the exact same statement applies to any organization – let the chips fall where they may!

Before World War II, there were many voices which purred softly in our ears, "We don't have a thing to fear from abroad. Why should we waste all our money in order to arm ourselves against an attack which will never come? Our oceans will protect us." Does this sound familiar? Well, the folly of such short-sighted ideas was clearly comprehended, thankfully, and we were able to survive. We did not heed this siren song, chanted by doubletalkers who tried to lull us into a sense of false security, while plotting our destruction at the same time. I do not think that this comparison is at all far-fetched. We are being threatened at this very moment by forces which actively seek to curtail our privilege or limit it. If we do not summon up the will and moxie to fight against these groups, we may soon discover one fine day that we are beyond the point of no return. Then it will be too late to do anything about it.

Can we allow our most prestigious single organization to continue on its present blithe course, denying or minimizing the dire necessity for decisive action, while all of our competitors are consolidating their strength for a stab in the back? For to me, a CB lobby in Washington means only one thing . . . a grab for more frequencies at our expense!

Well, how about it? Isn't it high time and beyond, that every ARRL director and officer be bombarded with mail, instructing him to call for a change in the League's old approach to this vital question? I urge and entreat you to give this your most profound attention and consideration. It may be the very last chance we will ever have. Please think about it. 73. . .K2AGZ ■

YO an interesting DX

George Pataki, ex YO2BO, YO2KAC
34–24 78th Street
Jackson Heights NY 11372

Romania, the YO land, is a beautiful country located in South Central Europe on the Black Sea, north of the Danube. It has wide plains, which are excellent for farming, sheep and cattle raising; hills with large vineyards; and the famous Carpathian Mountains covered with deep forests rich in coal, iron, gold, copper, and salt. The cities, growing industrial centers, have good schools and universities. Romania's oil fields and refineries are known worldwide, as is its nicest region: Transylvania.

Romania has eight amateur districts; from YO2 to YO9. Bucharest, the capital, is YO3. Its neighbors are HA, YU, LZ, UO5, and UB5. In YO-land amateurs are organized by the (Romanian Federation of Radio Amateurs) which maintains a large staff. Some of them are at the central headquarters in Bucharest, but most of them are in charge of the district radio clubs all over the country. The district radio clubs have their own councils which guide the activities of the rest of the clubs in the district, and the individual amateurs.

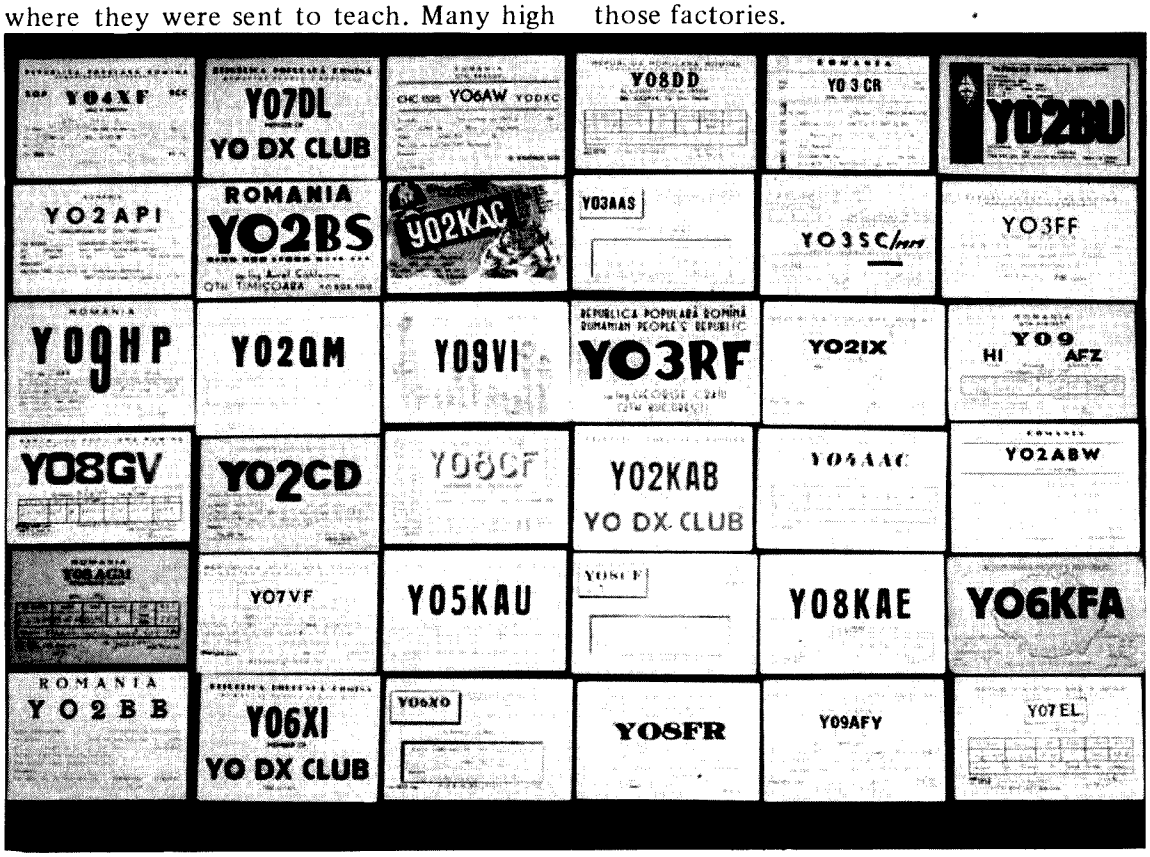
There are two basic forms of activity; the club and the individual station; co-operation between them is strong and useful for both. In YO-land there are a little over 1200 licensed radio amateurs.

The Club Stations

The club stations are easy to identify; they have a K after the number indicating the district. For example YO8KAN is a radio club in the city of Bacau. The Romanians, being very sociable, love to belong to a club. There they meet friends, operate the club station, do some work in the club's shop, read books or magazines in the library, get advice from the more experienced, or – this is very important – they can boast of the latest DX QSO or show around a rare QSL card.

The main tasks of the district radio clubs, which are financially supported by the government, are to guide, advice, teach, organize, and give material help to the other clubs and individual stations in the district.

The following district club stations, each having many operators, are very active on the air: YO2KAB in the important university city and industrial center of Timisoara, "the city of gardens"; YO3KSD in Bucharest, the modern capital of the YO-land, YO4KCA in Constantza, the famous port on the Black Sea; YO5KAU in Oradea, the city of hospitality, located in western Romania on the Tisza Plain; YO5KAI in Cluj, the capital of Transylvania, known for its very friendly



inhabitants; YO6KAF in Brasov, an 800-year-old town in the heart of the Carpathians, YO6KAL in beautiful Sibiu, an ancient town of medieval appearance; YO7KAJ in Craiova, a large industrial city situated on the Danube plain; YO8KAE in Iassy, the cultural and university center of Moldavia; YO8KGA in Suceava, center of the Bukovina region, noted for its 15th and 16th century monasteries, covered with lovely and authentic frescoes; and YO9KAG in Ploiesti, well-known for its rich oil fields.

In the capital city of Bucharest, YO3KAA is the club station of the Central Radio Club, the headquarters of the Romanian amateurs, and YO3KBN is its second station.

Besides district clubs there are many other clubs. For example, many universities have their own radio clubs. These are generally well-equipped, with a group of enthusiastic students operating the station. YO5KDK is the club station of the Pedagogic Institute of Cluj. After graduation, many of its operators, in love with amateur radio, organize new clubs in the schools where they were sent to teach. Many high schools also have radio clubs. YO4KCE in Galatzi was built and is operated by the organizing teacher and his best students. The teachers and the parents like to see the kids spending their spare time in a useful way. The students learn basic electronics and code. By operating the club station they are also increasing their knowledge in world geography, in foreign languages, etc.

In every city or village in Romania there is a "pioneers' palace" where the children can learn things normally outside the school cirriculum. YO2KAC, the club station of the pioneers' palace from Timisoara and YO9KDP of Cimpina are operated mainly by young high school students. Under the supervision of their teachers, they also do all the construction work and the maintenance of their station.

Many factories also have amateur radio clubs. For instance, YO3KBC is the station of a large electronics plant in Bucharest; YO5KDL is the radio club of a shoe factory in Oradea, and YO6KEM is the club station of a textile factory near Sibiu. These club stations were built entirely by technicians and engineers employed by those factories.

Some of the Romanian QSL cards received by W, K amateurs.

Aurel (YO2BS) Leo (YO2BM), and George (YO2BB) during their SSB expedition on the peak of the Semenic mountain. The receiver is a Lafayette HA-350 and the transmitter is homemade, built by George.

The Individual Stations

Many club members and operators of club stations also have individual stations at their homes. Some of them began in radio years ago as young pioneers. Mircea, YO2QM, and George, YO3FU, former operators of YO2KAC, are today top DX men. Aurel, YO2BS, who started his hobby as an operator of the district radio club YO2KAB, is now a broadcast chief engineer. George, YO3RF, is an internationally known oldtimer from Bucharest and cofounder of the YO DX Club. He has 260 countries confirmed and received 150 awards and certificates. George is very active on his own station and equally active in club affairs, teaching and helping the new generations of hams.

Cornel, YO3SC/MM, is on the trawler "Constantza." he is working a lot of DX and is visiting personally quite a few of the fellows he contacts. Another very active "Maritime mobile" is Stefan, YO4WV/MM.

Dietmar, YO7VS (ex-OE5ZIM, -OK8AAJ) is a radio technician for the Romanian Airlines in Craiova. He is an excellent DX man but he is more famous for his activity on VHF. On 144 MHz, Dietmar worked with 18 European countries, and his record is 1330 miles.

Using the meteor scatter technique he made 14 QSOs, the farthest with UA1DZ with only 30W input, at a distance of 1134 miles. Presently he is looking for a W–YO moonbounce QSO. Amateurs interested in this kind of experiment should contact him directly: P.O. Box 63, Craiova, Romania.

In Romania, there is a tendency to involve every active ham in club activity. Some teach code, others theory. Some are in charge of the shop or the library or the QSL bureau. Others are with the club station. There are committees for VHF, for field days, for organizing public exhibitions with gear built by amateurs. Other hams are managers for different YO awards and certificates.

A good example of teamwork was

shown in July 1968 by YO2BB, YO2BM, and YO2BS. They installed a rig in a chalet on the peak of the Semenic Mountain, on the southeast corner of the Carpathians. The altitude was 4760 ft; the weather was cold and rainy. But for 10 continuous days, their station worked hundreds of DX stations on 15, 20, and 80 meters. They used a homemade 100W SSB transmitter built by YO2BB, a Lafayette HA-350 receiver, a single-element quad for 15m and longwires for 80 and 20m.

Amateur radio activity in Romania is regarded as a sport and the amateurs are considered sportsmen. They often participate in competitions. The scores obtained on various national and international shortwave contests, code proficiency competitions, the results of the "foxhunts," like the quality in designing and building ham gear, determine the rank of an amateur radio sportsman.

For very high achievements, the National Counsel for Physical Education and Sport could confer special distinctions and honorary titles. A short time ago the following top YO hams received the "Master of Sport" title: Victor, YO6AW, from Brasov; Victor, YO7DO, from Craiova; and George, YO3RF; Petre, YO3FF; Vasile, YO3CR, from Bucharest. Vasile has been a ham since 1948, and has made over 10,000 QSOs. He also has nearly 200 countries confirmed, has more than 180 awards and certificates and is very active in club committees.

The competition among the hams is strong, but friendly. Many times an experienced ham will have around him at the club or in his home a group of youngsters, who help him and learn from him at the same time. The average age of the YO ham is below 30 and the number of licensed amateurs is growing rapidly.

In many tiny villages, as soon as electric power is introduced a beginner will build an amateur radio station. He is usually a teacher, or the agronomist, or the doctor of the village. Soon, others join him and spend their evenings together, watching him making QSO after QSO, then helping him build a new transmitter or install an antenna. And suddenly a new club is born.

YO awards

The Romanian Federation of Radio Amateurs issues 20 different awards, under the following general rules;

- Bands: 3.5; 7; 14; 21; 18 and 145 MHz.
- Mode: CW, AM, SSB, Mixed.
- Mode: CW, AM, SSB, mixed.
- All contacts have to be confirmed by QSL cards, YO cards being in the applicant's possession. Exceptions to this rule may be granted for QSOs made during the international contests.
- YO awards are not issued for various modes, but each class is a separate award.

The application and the log will be sent to: Central Radio Club, Box 1395, Bucharest 5, Romania. The log will be certified either by the awards manager of the association, or by two licensed amateurs, having checked the validity of the QSL cards.

The fee for any award and class is 7 IRCs or $1 (packing and mailing included).

All SWLs may get these awards in accordance with the rules.

The awards will be issued only after the YO stations listed in the application log have received the applicants QSL card. When there are fears that cards have been lost, the applicant is urged to send new QSL cards for the YO hams, together with his application.

Here are some of the YO awards:

YO-WAD (Worked All YO Districts). The award is issued for two-way contacts with YO stations located in all YO districts, namely: YO2, YO3, YO4, YO5, YO6, YO7, YO8, YO9.

The award has 3 classes:

- Class 1: for working all 8 districts,
- Class 2: for working 6 districts,
- Class 3: for working 4 districts.

Each YO district worked will be awarded by a specific seal on the certificate.

A district is considered to be fully worked, after two-way contacts with a minimum number of YO stations located in that district, depending on the applicant's location zone, as follows:

YO–AM (YO Alma Mater). This festive award is issued to celebrate the 100th anniversary of Bucharest University.

Location zone	Number of QSOs needed for each district		
	Class 1	Class 2	Class 3
15, 16, 20	10	6	3
14, 17, 21, 33, 34	6	4	2
All other zones	3	2	1
YO hams	15	10	5

A YO station may be worked but once.

YO–AM (YO Alma Mater). This festive award is issued to celebrate the 100th anniversary of Bucharest University.

Depending on his location, the applicant has to gather the following number of points:

Location zone	Needed points	Points scored per contact				
		3.5	7	14	21	28 MHz
15, 16, 20	60	3	1	1	4	8
14, 17, 21, 33, 34	40	4	2	1	3	6
All other zones	20	8	3	1	2	4

Working the same YO station on several bands, the points scored for these contacts will be multiplied by 2 for 2 bands, by 3 for 3 bands, by 4 for 4 bands, and by 5 for 5 bands. For instance: A ham located in zone 33 had 4 contacts with the same station on 3.5; 7; 14; 21 MHz bands. The overall score for these contacts will be: 4+2+1+3=10x4=40 points, which is enough to get the award.

YO–UBZ (Worked Balkans Peace Zone). This award is issued in 3 classes, in accordance with the following rules:

(a) European stations must carry out two-way contacts with a minimum number of countries and districts as follows:

– Class 1: 6 countries and 18 districts
– Class 2: 5 countries and 15 districts
– Class 3: 4 countries and 12 districts including a minimum of 6 YO districts.

(b) Stations outside Europe:

– Class 1: 5 countries and 10 districts
– Class 2: 4 countries and 15 districts
– Class 3: 4 countries and 12 districts including a minimum of 3 YO districts.

Balkan countries and districts considered for this award are:

1. Bulgaria LZ1, LZ2
2. Greece SV
3. Crete SV
4. Dodecanese SV
5. Turkey TA (European part)
6. Albania ZA
7. Romania YO2, YO3, YO4, YO5, YO6, YO7, YO8, YO9.
8. Yugoslavia YU1, YU2, YU3, YU4, YU5, YU6.

The award is also issued for two-way contacts with one YO station, and two different stations in two different countries, on 2m band.

YO–10 x 10 (Worked 10 YO on 10 Meters). There are needed 10 two-way contacts with 10 YO stations on 10m band.

A YO station may be worked but once, regardless the mode of the contact. There are similar awards for all bands (15 on 15m, 20 on 20m, etc.)

YO–DX–C (Worked YO DX Club Members). There are needed two-way contacts with YO DX club members, as follows:

Romanian hams	10 QSOs
Hams in European countries	5 QSOs
Hams in the rest of the world	2 QSOs

The members of the YO DX Club specify this quality of their QSL cards.

Foreign amateurs completing the required conditions for the award during a YO contest, may apply for honorary membership in the YO DX Club.

YO–45–P (Worked Parallel 45). There are needed contacts with radio amateur stations of the countries located on 45th parallel:

North America: W7, W0, W9, W8, VE3, W1, VE1, FP8
Europe: F, I, YU, YO, UB5, UA1, 3, 4, 6
Asia: UL7, UI8, JT1, BY–BV, UA0, JA.

MULTI-ANTENNA COUPLER

New!

Eliminates Antenna Switching

Shown above: Model 3, for 10/15/20 meters. Terminals: SO-239 $29.95 ppd.

- Change bands without having to switch antennas!
- Combine your antennas into a multi-band antenna system while retaining optimum antenna performance on each band!
- Coupler feeds any combination of antennas from a single transmission line! Saves operating time! Saves coax and switches!
- Coupler isolates the line from all antennas but the one in use!
- Works with all types of antennas! Handles full legal power!
- Models available for any bands, 2 to 160 meters! Weatherproof!

Write for free information on a coupler for your antenna system, listing antennas and bands used. Non-amateur frequencies available. Indicate impedance and type of line used.

POST OFFICE BOX 458, OCEAN BLUFF, MASSACHUSETTS 02065

Campaigning for ARRL Directors

It's nearing campaign time for directorships in the ARRL, and a lot of good men – and bad – will be actively seeking office. You readers have practically convinced me that the best way to improve the League is from the inside, so maybe an effective group of directors would be the right start.

So . . . how about it? Do you know of any candidates who are especially suited to serve? Or who aren't? Write 73 and give us the lowdown on the prospective candidates in your division.

And how about the directors already in office? How are they performing? You *can* do something. Write your division director a letter and ask how he feels about issues you consider important. Does he think a lobbyist in Washington would help ham radio? How does he feel about incentive licensing? What are his views on repeater rulemaking? About the increase in license fees? Does he plan to put any pressure on the boys at headquarters?

Find out if he keeps informed on League affairs. Ask him if he knows what lawsuits (involving amateurs) the League is helping with. What kind of help is the League offering? How many dollars? How much of the League attorney's time?

You hold a lot of power in your hand as a League member. And you can use it very effectively by telling the whole amateur world which individual you think is best qualified to hold office in your division.

. . . K6MVH ■

Please Use Your Zip Code When Writing 73

PEP's *SPECIAL!*

CIRCUIT BOARD COLLOSSAL

Loaded with components up to $100.00 value. Bought out one supply house—FIRST come—FIRST served!

All Different! All Complete! First Line Units!

If you don't feel that you got your money's worth—full return guaranteed.

3 DIFFERENT GROUPINGS TO CHOOSE FROM

GROUP A – **Actual Value $15.00 – PEP Price $1.25**

SAMPLE A–1: 200 diode – 7 transistors – over 50 resistors – complete with board.

SAMPLE A–2: Four I. C. Mounting Blocks – 3transistors – over 25 resistors – complete with board.

GROUP B – **Actual Value $20.00 – PEP Price $1.75**

SAMPLE B-1: 8 I. C. Mounting blocks – over 50 resistors – 32 transistors – over 30 diodes – complete with board.

SAMPLE B-2: 32 transistors – over 100 resistors – capacitors – over 15 diodes – complete with board.

GROUP C – **Actual Value $50.00 – PEP Price $4.50**

SAMPLE C-1: 22 in-line I.C.s – over 75 diodes – 20 trans. – over 50 resistors – capacitors – complete with board.

SAMPLE C-2: 22 in-line I.C.s over 50 diodes – over 50 resist – capacitors – complete with board.

12X100 MM ROD $1.25

– Class 1: 18 contacts with 18 countries

– Class 2: 12 contacts with 12 countries

– Class 3: 6 contacts with 6 countries.

One contact with each country. A YO contact is obligatory in all cases.

Valid contacts: after January 1, 1960

YO–25–M (Worked Meridian 25)

There are needed contacts with amateur stations of the countries on the 25th meridian:

Europe: LA, OH, UP2, UQ2, UR2, UC2, UB5, YO, LZ, SV

Africa: 5A, SU, TT8, ST, TL8, 9Q5, 9J2 (VQ2), ZE, ZS1, 2, 4, 5, 6.

– Class 1: 18 contacts with 18 countries

– Class 2: 12 contacts with 12 countries

– Class 3: 6 contacts with 6 countries.

One contact with each country. A YO contact is obligatory in all cases.

YO–20–Z (Worked Zone 20). This award is issued in three classes, for contacts made with amateur stations of the countries belonging to zone 20:

Bulgaria (LZ), Crete (SV), Cyprus (5B4,ZC4), Dodecanese (SV), Greece (SV), Israel (4X4), Jordan (JY), Lebanon (OD5), Romania (YO), Syria (YK), Turkey (TA) as follows:

Location zone	Minimum No. of countries worked		
	Class 1	Class 2	Class 3
15, 16, 20, 21 34	10	8	6
14, 17, 22, 23, 33, 35, 36, 37	8	6	4
All other zones	6	4	2

A YO contact is obligatory in all cases.

YO–5 ON 5 (Worked 5 Continents on 5 Bands). There are needed 5 two-way contacts with 5 DX continents, each on a different band; 3.5; 14; 21; 28 MHz.

The pan pipes are played in Romania's southern provinces (YO3, YO4, YO7, and YO9).

There are 6 continents: Asia, Africa, Europe, North America, South America and Oceania. Own continent does not count for this award.

Additionally are needed a number of YO contacts as follows:

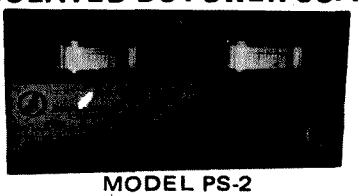
European stations: 3 YO contacts

DX stations: 2 YO contacts

YO–LC (Worked YO Large Cities). There are needed anumber od contacts with YO stations residing in the large cities of Romania:

Bucharest	Lugoj
Alexandria	Medgidia
Arad	Medias
Bacau	Oras Gheorghiu-Dej
Baia Mare	Oradea
Birlad	Petrosani
Botosani	Piatra Neamt
Brasov	Pitesti
Braila	Ploiesti
Buzau	Resita
Calarasi	Roman
Cimpina	Rosiorii de Vede
Cimpulung Muscel	Rimnicu-Vilcea
Cluj	Sibiu
Constanta	Sighetul Marmatiei
Craiova	Sighisoara
Deva	Suceava
Fagaras	Timisoara
Focsani	Tirgul Mures
Galati	Turda
Giurgiu	Tulcea
Hunedoara	Turnu-Severin
Iasi	

Only one contact is allowed with each of the cities mentioned above, regardless of band, or mode.



– Class 1: 30 cities
– Class 2: 20 cities
– Class 3: 10 cities

YO–NC (Worked Namesake Calls). This award is issued for at least 5 two-way contacts between partners having the same personal 1, 2, or 3 call letters after the district (or state) figure.

For instance: I1ACD, JA1ACD, LU1ACD, WA1ACD, PY2ACD, etc. The same station may be worked but once.

Radio amateurs having a callsign with two call letters after the figure, must make

REGULATED DC POWER SUPPLY

MODEL PS-2

The model PS-2 regulated power supply is designed to meet the needs of the experimenter, technician, engineer, service facility, etc. It features variable output voltage and can deliver an output current of 2.0 amps continuously. The high degree of reliability and ruggedness of all-silicon, solid state circuitry has been incorporated in this compact inexpensive power supply. **SPECIAL PRICE $34.95**

RG 196 AU 50 ohm teflon coaxial cable. Outside diameter .080" RF loss .29 db per foot at 400 Mhz. Silver plated shielding and conductor. Used for internal chassis wiring, antenna coupling, RF coupling between stages, etc. Random lengths from 35 foot to 150 foot. Colors: black, red, brown, blue, grey, orange. Regular price- 23¢ per foot. Our price 5¢ per foot $3.00 per 100 ft.
455 Khz ceramic filters type BF-455-A. These filters will help to sharpen the selectivity of most sets using 455 Khz IF's. Use across cathode bias resistor in place of a capacitor, or in transistorized sets, across the emitter bias resistor. Impedance is 20 ohms at 455Khz., DC resistance is infinite. Impedance increases rapidly as you leave 455 Khz. Plan your own LC filter circuits at very low cost.

also a "namesake" contact with a YO station.

Some of these awards are easy to obtain, others are more difficult. It is a worthwhile effort trying to get any of them. Larry, K2UMM, found that he satisfied the requirements for 9 different YO awards. He made up the logs and sent for them right away.

Romanian hams QSL almost 100% and it takes approximately 3—4 months to get these beautiful awards.

In YO land, the hams cannot subscribe to the western radio publications and they are always appreciative when they receive some old copies of 73, QST, CQ or Callbooks.

Romania is a very interesting country. Its natural beauties and the friendliness of its inhabitants attracts more and more tourists. The YO amateurs stretch the rules of hospitality when a foreign amateur visits their country. In a short period of time the following visiting amateurs got the red-carpet treatment: Franco, I1FO, from Milan, Italy; Zbyszko, SP5ZK, from Warsaw, Poland; Janos, Ha5AM, from Budapest, Hungary; Ludwig, DM2CHM, from Leipzig, Germany; Jim, W8FXP, from Jamestown, Ohio; George, K8NEY, from Albion, Michigan; and Lee, W6MNN, from Gridley, California.

Working an amateur in another country is a little like being there. By talking to a ham you can learn about his life, his country, his goals. Why don't you try to learn a little about a far away but interesting land, YO country?

. . .YO2KAC

"Get this, some lid's giving the call UFO!"

"He started building it 3 weeks, 8 blown fuses, two hundred dollars ago."

Neater Cabling with Nylon Cord

The November 1968 issue of 73 contained an article describing some of the fine points of cabling.

After your cabling is complete and the cord ends cut off to 5/8" or so, apply the flame of a match or cigarette lighter. Take care not to burn the cable or components. The *NYLON* will melt very rapidly and form a lump at the junction with the wiring. This will simultaneously accomplish two ends. The lump will prevent the end of the cord from pulling through the knot and loosening the cabling, and at the same time the usual frayed end will disappear into a neater, more finished looking termination.

G.E. MODEL AK-4 Clamp on Voltmeter–Ammeter – New with leather case and test leads.
Shipping wt. 6 lbs $59.50

STARRETT MASTER PRECISION LEVEL #199 – New in wooden case.
Shipping wt. 10 lbs. $50.00

SET OF 3 STARRETT MICROMETERS – 1" to 3" – New in wooden case.
Shipping wt. 10 lbs $59.50

MODEL 28 KSR TELETYPE KEYBOARD – good condition.
Shipping wt. 30 lbs. $95.00

100 MFD – 3000 volt DC Capacitor 14" x 6" x 8".
Shipping wt. 40 lbs. $25.00

30 VOLT CENTER TAPPED TRANSFORMER – 115 VAC primary – 24 to 30 volt secondary at 10 amps or 12 to 15 volts at 20 amps.
Shipping wt. 15 lbs. $10.00

6.3 VOLT Filament transformer – at 10 amps.
Shipping wt. 2 lbs. ..... $ 3.95

BURGLAR ALARM FOIL TAPE – 300 foot roll.
Shipping wt. 1½ lbs. ..... $ 3.50

BURGLAR ALARM KEY SWITCH
Shipping wt. 1 lb. ..... $ 4.30

BURGLAR ALARM MAGNETIC SWITCH – SPST.
Shipping wt. ½ lb. ..... $ 2.50

BURGLAR ALARM DOOR CORDS
Shipping wt. 1 lb. ..... $ 1.00

Minimum order $5.00. Sorry, no catalog at this time. Write for specific items. Watch for our ads in 73. Stop in and see us when you're in St. Louis.

the permaflex key

- both a twin lever & straight hand key in a pivotless 2 paddle design.
- gives instant choice of automatic semi-automatic & straight hand keying when used through an electronic keyer.
- use directly with any transmitter
- 8 amp. gold diffused silver contacts adjust from 0-.060" & 5-50 grams.
- distinctive blue paddles are of rugged G-10 fiberglass epoxy.
- cabinet is 16 gauge polished chrome steel: 1.95" sq. x 3.75", paddles extend 1.25", weight 10 oz.
- silicone rubber feet for stability.
- 100% US made & guaranteed for 1 yr.

Repeaters

Your articles and backing for repeaters (FM) and associated operation are great, although your open-repeater-directory was not fully accurate. It was, however, stupendous, and of very effective help during my recent trip across the country and back. Maybe in a year or so, when the FCC gets a decent repeater rules concluded, you can call for info and publish a good, up-to-date list, under separate cover and for $1, with a new directory published yearly. Lots of luck.

Ray Bilger W3TDF

Directories are hard to keep up-to-date, but we're trying. The update currently being prepared has more than 100 new repeater entries plus about 100 changes in existing relays.

. . . Ken

Propagation

Please convey my thanks to your propagation analyst, Mr. John Nelson. His successive forecasts of three poor Sunday's in a row have been 100% accurate from this QTH. So thanks for this service. . .very much appreciated.

Neil Johnson W2OLU
74 Pine Tree
Tappan NY

Our analyst has received national acclaim and many honors for his predictions, many of which baffled even government experts.

. . . Ken

Favoritism

Rev. Peter Gonos (K6GZN) takes the FCC to task for not giving a blind person special consideration ("Letters," June 1970). I agree that the examiner was a grouch, but publishing vague accusations is not the way to handle this situation. Public servants with a public-be-damned attitude can be removed from contact with the public if one complains in the right places. I assume K6GZN could name names, place, time, and other pertinent facts.

Robert Newman WA7IEH
Box 283
Estacada OR

Censorship

When I picked up a copy of the FM Repeater issue of 73 at a local ham store, I was very favorably impressed.

I then noticed a column which mentioned the writer's objection to Latin America-to-Miami phone patches (he'd rather that *he* use the frequencies). Well, he's entitled to his opinion, though I'd say DX phone patching is "more important" than DX ragchewing.

He then goes on to suggest (very obliquely, of course) that we ship the Latin Americans in the

Miami area back where they came from. He thus shows his ignorance of what belongs in an amatuer radio magazine, and, perhaps, of what it means to be an American, and what makes this country great.

Anyone who could write something like that is beyond reaching, but where was the editor? I hope to see a retraction in a future issue of 73, so that I may, in good conscience, subscribe to what appears to be an excellent radio magazine, when it sticks to that area.

Michael Gershman WA3OOB
11550 Stewart Lane
Silver Spring MD

You are calling for censorship. . .are you really in favor of that? Do you really feel that I should not print things in 73 that I do not agree with? 73 prides itself for its policy of publishing all intelligent sides to various issues.

. . . Wayne

Feedback

The following is an adaptation of an experiment common in most basic college physics courses.

There is an easy way to automate the comparison of light intensities used in KICLL's wattmeter. (August 73) Mount the two bulbs rigidly and place a small square of shopping bag paper, which has a spot marked in the center, with margarine or some other light oil, exactly equidistant between the two bulbs. When the bulbs have the same intensity, the spot on the paper will seem to disappear. The paper must not be exposed to strong external sources during measurements. This method should also greatly increase accuracy.

Alan P. Biddle WA4SCA/7
Box 10866
Tuscon AZ

The League and 73

I notice you punching up the ARRL which I think needs to get up with times. I don't subscribe to QST; for one reason, it costs too much for the couple of writeups I could get some use out of once in a while. The rest of the magazine is filled with contests and League doings, and when you save a pile of QST you got about 9 times as much paper as you need to fumble through to find something on that antenna or what have you. I do think ARRL is doing a good job on the code practice sessions and I do think that our extremists should quit QRMing that session each night for the short time they are on. After all, they have been doing it for years now so the oldtimers should know it's there.

my feet in preparing for the General class examination. Having had some electronic instruction at Fort Monmouth back in my Army days, I have concentrated mostly on the code, believing that the theory wouldn't take much effort. I have been brushing up on theory for quite some time by studying an NRI course, supplemented with a couple of AMECO books and several of those published by the ARRL. It would seem that this would be sufficient preparation for the FCC exam. However, I will have to admit that I have never *really* understood some of the very basic principles of electricity and electronics and I have been relying on my ability to memorize what I have repeatedly studied, hoping that someday the understanding would finally dawn.

Last weekend I stopped by the local electronics store to pick up a copy of QST and I happened to notice on the cover of 73 that here was a new study series on getting the General ticket, so I bought both the July and August issues. I can't explain what a stroke of good fortune this has turned out to be for me. I had just about decided that thorough understanding of electronic and electrical theory required some natural ability that I happened to be born without.

Thanks to 73 I now have a much better understanding of the relationship of circuit components, voltage and current in electrical circuits, and that of resistance versus reactance. Looking back on the past, I can see that my particular problem has been that when I would read something I didn't quite clearly understand, I would skip through that section of the material with a vague idea of what the writer was trying to convey and go on to something easier to comprehend. This, obviously, has hindered my ability to approach new knowledge with comparative ease.

More specifically, I have been able to understand how each electrical component works by itself and have learned the characteristics of various circuits, but I have always had trouble understanding the interaction of the components of circuits and the formulas used to arrive at answers to required values. I am anxious to study the next installment and I feel that when I take the exam for the General ticket I will be grateful to 73 for giving me a sorely needed lift.

Having gained from studying this material, I began reading some of the other articles in the two issues and have discovered that 73 is the most refreshing ham publication I have read. To a beginner it is a big help to know that someone is interested in his efforts to become an amateur and willing to be of help, rather than taking the attitude that amateur radio is for a selected group in which membership is by invitation only.

John Leach
Metairie LA

Hobby License

Apparently your left hand does not know what your right hand does! I refer to your coupon asking that the FCC give up the 220 MHz band to a hobby type service requiring no examination.

In your editorial you make the statement, "Since the ARRL has set aside $100,000 for the defense of our amateur frequencies it seems

logical to me that it is up to them to make a definite move in this direction." Can you explain to me whi in one statement you indicate the ARRL is not defending our frequencies to the utmost, yet in another portion you are attempting to give away one segment of our frequencies to a group of people in the same category as the CB'ers?

You indicate in your Action Coupon, "Amateur radio has been stalled for seven years now. . ." Apparently you have not participated in the hobby of amateur radio for seven years because I can hardly see indications of amateur radio being stalled. It would seem to me that amateur radio has made more progress in the last ten years than they had in the preceding ten years.

I cannot see how giving 220 MHz to a group of people without examination could correct the present chaotic conditions in CB. If you will think back a few years you will remember citizens radio originally was in the 450 MHz band and was used very little by CB'ers.

Robert Johnson WA0 PVW
5544 Blue Ridge Blvd
Raytown MO

The proposal is not to GIVE part of 220 away. It is to USE part of 220 to attract more hams. For the past seven years the number of new amateurs has been declining.

. . . Ken

FM Calling Channel?

The frequency must of course be one not presently used, or used by the least number of persons. I would suggest that 146.910 be considered.

Robert S. Katson W1HBH
59 Meadow Brook Dr.
Monroe CT

Do we really need it? 146.94 is admittedly a national repeater output frequency, but it IS monitored by just about everyone on FM. FM'ers in repeater areas can operate through their local systems and get a contact almost anytime, particularly where there is an emergency. Where there is no repeater, there is still .94. When it is so easy to contact another station on .94, why try to set up another channel — one that probably wouldn't be monitored anyway? Repeater transmissions are usually kept short enough to

GUNSMOKE?

Blow your mind on our back issue bargain bunch, 30 (count 'em) assorted (we hope) back issues, all before 1968, for the incredibly low price of $6 postpaid (hardly pays for the postage). These are packed by slave labor (to cut costs) so please ignore notes calling for help, etc. that may be slipped into the bundles. **73 Gunsmoke, Peterborough NH 03458.** Send cash, check or negotiable securities.

allow any user to get in within a minute or less. And if users get out of the habit of "tail-ending" other users, a brief monitoring period would be available at the end of each station's transmission. Who could ask for a more efficient emergency communications setup?

. . . Ken

Article Policies

Some other ham magazines may take years to pay for an article, but you guys are something! You paid me $20 for a short article which you never printed (sent to you 1 year ago).

Gabe Gargiulo WA1GFJ
160 Elm
North Haven CT

We liked your article and bought it. Now it's working its way toward the top of the heap.

. . . Ken

From the Lunatic Fringe. . .

I have been reading your magazine for many years and have enjoyed it but I never felt that your comments on the ARRL, and your advice and insinuations were in good tast or even good sense.

I do feel that you are doing ham radio and hams a great injustice, since your attacks on the ARRL do incite the lunatic fringe that has infiltrated ham radio, and these degenerate vicious slobs play such tricks as jamming of the CW practice sessions, hurting new hams or potential hams who are trying to get that code practice, which is being denied them. In short, this is at least one of several forms of damage and injury, your tirades may be responsible for. Only the lunatic fringe and the weak minded would respond to those articles and only in the modes I have mentioned.

Also I noticed that when that gang of long-haired cowards utilized the college radio clubs to propagate their destructive and idiotic policies on the air and on ham bands, those who wrote to your magazine and objected to same were answered with jeering and smart alecky retorts. If you don't think that such use of the ham bands *could* very easily result in total loss of ham privileges, you are not fit to be running a ham magazine.

I have decided not to renew my subscription, and if enough of us oldtimers feel the same about it, you may find yourself going into bankruptcy, unless of course, you are being financed by Russia, Cuba, or dope sales.

Jacob Dubrusky W2LVR
Box 482, Flushing
Queens, NYC NY

Good Grief! *. . . Ken*

Code

I have been reading with great interest the comments by some hams about the new licensing requirements. . .particularly about code requirements. I would very much like to become a ham operator. Only one thing keeps me from fulfilling that desire: CODE.

I have spent endless hours trying to acquire a code speed sufficient to get a license, but have

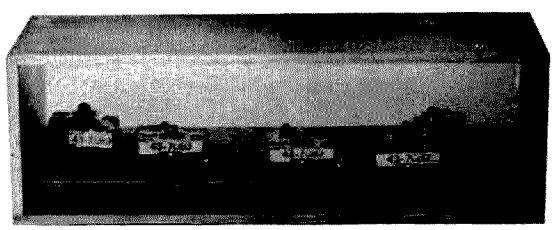
never been able to pass the test. At one time I received three hours of code training daily, five days a week for six months; but at the end I could not pass a 16 wpm test.

However, I would make a good ham operator, as far as technical ability is concerned. I have held a First Class radiotelephone license for over 25 years. During that time I have been actively occupied in radio and electronics, in many different areas. The technical test would be no problem and I might even contribute some worthwhile ideas to ham radio.

I don't believe that code will ever completely die out, but it has been replaced in many ways with other types of transmissions. Now you can even buy an automatic code sender that will convert typed characters to code equivalents. Very little would be lost to the ham world if noncode operators were licensed. Those who wished to operate with code could pass a supplemental code test.

But please let's not keep up the howl... "anyone can pass the code if they really try," because I have really tried – and can't!



Ernest T. Robarge

Satisfied Lifer

The time has come for another auto de fe. Please enroll my second son for life, for which I enclose $50. You might be interested to know that this is the third lifetime subscription to your magazine I've given away. The idea is to lure the recipients into the more technical end of the sport.

73 Reader Service Coupon

Now we don't say that every single reader must buy every last product advertised in 73. We believe that, but we don't say it. The very least every reader can do is to put on a show of interest in the products herein advertised. To make this a simple task, even for the laziest reader (now there is a contest for you!), we have cleverly arranged the advertising index to double as a readers service coupon. All you have to do is tear it out (or photocopy it) and send it in with the appropriate boxes marked. (We have a prize for the most boxes marked . . . a silent prayer of thanks from the publisher). We'll accept postcards, slips of paper, or almost anything else that lists the companies you want to hear from and your address.

No one likes to go into a store without buying something, right? It is the same with these information requests. You will be expected to buy something. Oh, it doesn't have to be a $50,000 antenna system, but it should be something modest . . . a transceiver . . . a linear . . . you know. We'll leave the decision up to you, knowing that we can trust you to do the right thing.

And we are definitely not saying that the use of this service coupon has any curative powers, but we cannot but notice that many readers report remarkable relief from simple backache, headaches, lumbago, and acid indigestion after sending in their coupon. Why take any chances?

November MCMLXX — Monthly Ham News of the World — 73 Magazine

ELEVENTH ANNUAL NOVEMBER ISSUE

Through thick and thicker 73 has, to the disappointment of its detractors, somehow managed to survive. This survival has frequently been quite marginal, as the gaunt but dedicated little group which publishes the magazine will testify.

One of the things that has kept morale high at 73 is the ability to publish humorous little items which are obvious only to the more intelligent readers, items such as the announcements of new certificates for amateurs contacting the editors of the other ham magazines, knowing full well that these chaps are inactive and have been either for years or life, and have their call letters as a subterfuge because they are editors.

It is an interesting statistic that 73 has, in its ten years of life, published almost as many technical and construction articles as QST has in fifty years! In its short lifetime 73 pioneered first the Nuvistor, then the transistor, and now the IC. The large number of articles published has allowed 73 to cover all aspects of the amateur radio hobby while still pushing the new developments such as ATV, RTTY, and FM.

The editorials in 73, though often accused of being anti-ARRL by League stalwarts who either have not read them or else have read them carelessly, are proamateur radio and anti any person or group who is doing battle by our Nell. Where the ARRL has done particularly despicable things such as at the New York World's Fair, in the Don Miller affair, and things like that, 73 is critical. Would you have it any other way?

No 73 Display At Hudson Convention

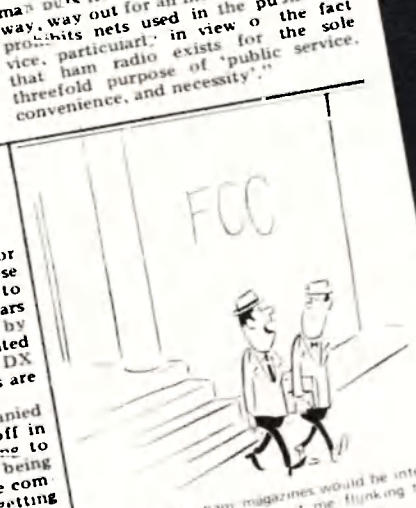
Despite assurances from several ARRL officials that a 73 display and booth at the New York Hudson Division ARRL Convention was out of the question, both the publisher and editor tried valiantly to convince ARRL Director Daniels to let the magazine in. He flatly and steadfastly refused to permit 73 to exhibit either in its own booth or in conjunction with any other exhibit.

Hudson Division ARRL members should be proud of Director Daniels' strength of conviction, no matter what fairness and decency would seem to demand of him.

ZA2RPS COMES THROUGH

The OH2BH expedition to Albania in August was over almost before it started, with under 800 contacts made before being shut down by authorities. Thus not too many amateurs were convinced that Frank Turek DL7FT would be able to pull off his promised try at getting on from ZA.

As reported in the West Coast DX Bulletin, Frank was supposed to start operation about September 15, but was only heard for a short time. The rumor mills started grinding at full tilt. 1. He would be on CW only. 2. He would favor California stations. 3. He was back in Germany and being worked from home. 4. His papers were not in order and he was not allowed into Albania. 5. He was on the air but from outside Albania. 6. The transmitter was giving trouble. It was a tense time for the DX'ers indeed.



On September 15th Frank and DJ0UJ opened up full bore and spent full time working everyone available until 0800 Friday (18th). Few serious DX'ers missed working Albania this time.

EYEBANK DEFIES FCC

In spite of the notice of illegal operation issued to operators of the renowned eyebank net by the Federal Communications Commission, the net is continuing to function routinely. The FCC says the eyebank net is illegal because it was formed originally by the Lions Club, a nonamateur organization. But hams don't agree with the ruling. "Public opinion, ... one amateur, is on our side. ... When the FCC gets enough power to jeopardize the lives of American citizenry, things are bad. But when the Commission actually uses that power, things are intolerable." The only way to bring the matter to a head, he indicated, was to ignore the FCC ruling and wait for the fireworks.

In Washington, FCC staff members are themselves more than a bit embarrassed by the situation. James Barr, chief of the FCC's Safety and Special Services, blames the hams for the predicament. It was a ham who brought the whole thing about, he said, because he wanted a literal interpretation of a somewhat ambiguous ruling. "Somebody asked a question and we had to give a straightforward answer. ... It would be better if they didn't ask the question."

Some hams, though, throw the blame back on Barr. His interpretation of the ruling, they say, borders on the sublime. As one noted amateur spokesman puts it: "The Fed has got to reach way, way out for an interpretation that prohibits nets used in the public service, particularly in view of the fact that ham radio exists for the sole threefold purpose of 'public service, convenience, and necessity'."

"Which of the ham magazines would be interested in a news item about me flunking the General 73 times?"

YI MAY BE ACTIVATED

Iraq is now the most unworked country in the world and, considering the Mideast situation, activity there at this time seems unlikely. Martin OH2BH promises to make a major try from the Finnish embassy ... This boast might be dismissed if it were not for his history of coming through on these promises. Martin was the first one to make it from Albania in many years and his operation there, followed by DL7FT, took 3A off the most wanted list for just about all of the top DX hunters. The October 17th pileups are frightening to contemplate.

Martin expects to be accompanied by OH2SE and they will stop off in Lebanon for a week before going to YI. One more document is being awaited before everything will be complete. The DX fraternity is getting edgy, beam headings for Iraq are being posted on operating desks, and airmail envelopes for the QSLs are already being addressed in expectation.

73 Magazine is published monthly by 73, Inc,. Peterbcrough, New Hampshire 03458. Subscription rates are $6 for one year in North America and U.S. Zip Code areas overseas, $7 per one year elsewhere. Two years $10 in U.S. and $12 overseas. Three years $14, and $16 overseas. Second class postage paid at Peterborough, N.H. and at additional mailing offices. Printed at Menasha, Wisconsin 54952 USA. *Entire contents copyright 1970 by 73, Inc., Peterborough, N.H. 03458.* *Phone: 603-924-3873.* *The magazine would be a whole lot thicker if you would let manufacturers know that you appreciate their support of 73. We could print a big lump of pages and go out in a glorious blaze of bankruptcy, but we prefer to be conservative and give you the number of pages the ads will pay for. If you can help convince advertisers to use 73 you will have a bigger and more enjoyable magazine. If you let them advertise in the other magazines instead then you get skinny reading.*

November MCMLXX | Monthly Ham News of the World | 73 Magazine

NEW PROPOSALS FOR ITU AIRED BY FCC

The latest Commission proposals for presentation to the 1971 World Administrative Radio Conference (WARC) of the International Telecommunication Union (ITU) to be held in Geneva, Switzerland, in 1971 have been issued by the Commission in Docket 18294.

A proposal by educational groups to allocate the 108 MHz frequency band for FM direct satellite broadcast was rejected because the Commission said that the signal from the satellite would represent a potential interference source over roughly one-third of the world. The current U.S. proposal covers a multiplicity of channels in the 88–100 MHz band.

A proposal suggested by some educational groups to reserve the 470–890 MHz band for direct satellite-to-home broadcast, the Commission stated, is consistent with the Commission's footnote accommodation of television broadcasting from space in the frequency band 614–890 MHz.

The suggestion by these groups to reserve the 2500–2690 MHz band exclusively for educational TV, public TV services, and other educational and noncommercial communications was not adopted by the Commission. Comments were invited, however, with respect to definite proposals to use this band in a manner compatible with other existing or proposed uses.

designated non-Government communication-satellite service bands for use as up-links.

The Commission retained in its proposals for the broadcasting satellite service a definition of the term "direct reception" as encompassing both individual reception by members of the general public and by those engaged in community reception-group viewing or listening. The Commission explained that its proposal visualized an evolutionary process beginning as a communication-satellite service to conventional earth stations for program distribution, progressing to a process in which service could be rendered to smaller earth stations for local distribution systems, and finally becoming a direct satellite-to-the-home service.

The Commission modified its proposals to include the requests of amateur radio service organizations that power flux density limitations not be imposed against the service, but that the service be governed by the normal constraints inherent to secondary status and regional allocations under which they have conducted terrestrial operations over the years – with the added stipulation that space techniques be permitted in the shared bands only if a reliable means of telecommand is provided to control emissions so as to prevent interference to stations of a primary service in the band. The Commission also suggested that amateur groups be given authority to use exclusive worldwide bands in the high frequency spectrum for space applications.

To minimize the probability of radio interference to space and planetary studies by radio astronomers, the Commission proposed that the WARC adopt a resolution urging the ITU member governments not to transmit from spacecraft in certain frequency bands in the region above the earth's ionosphere or from locations that could cause interference on the far side of the moon. It also suggested that the band 21.850–21.870 MHz be allocated exclusively to the radio astronomy service.

Interested parties were invited to file comments on these proposals by September 23, 1970, and replies by October 5, 1970. The Commission said it anticipated that the formal United States proposals would be transmitted to the Secretary General of the ITU on or about January 1, 1971, and that it would not expect to give favorable consideration to requests for extension of time for filing comments.

FCC Waives Third-Party Rule For Australis-Oscar

The U.S. and Australia have agreed to a temporary exemption to the international limitations on third-party communications, the FCC says. Chief James E. Barr, FCC Safety and Special Services Bureau, confirmed the exemption in a letter to E.J. Wilkinson, the director general of Australia's version of the FCC.

Barr said the waiver would be valid "between certain Australian amateur stations and United States amateur stations to permit the exchange of information on matters relating to the next amateur satellite experiments." The arrangement is effective now and will remain in effect until "four months after the satellite ceases to transmit."

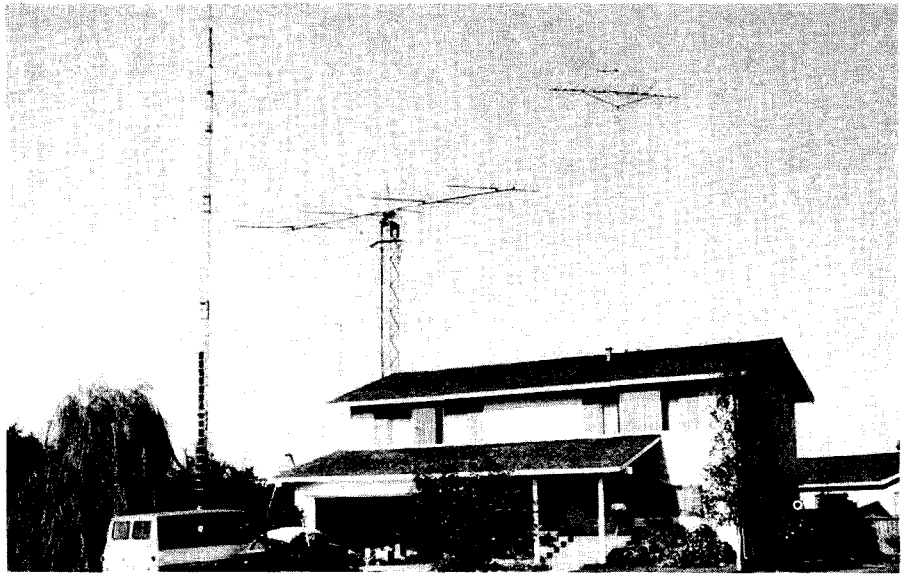
HAM LOSES FIGHT TO KEEP ANTENNAS UP

The current U.S. proposal for the use of the 2550–2690 MHz band contemplates space-to-earth transmissions in the earth sciences satellite service, with one or two sophisticated earth stations, remotely located, using extremely sensitive receiving systems capable of using power flux densities well below the sensitivity of Instructional Television Fixed Service receivers; and, in the 2500–2550 MHz band, communication satellite operations in Alaska, space-to-earth. In each case, the band would be shared with terrestrial services.

Broadcasting network interests, commenting on Commission proposals, expressed general agreement with tentative U.S. proposals, but stated that they are exploring alternative domestic satellite and terrestrial program distribution systems and may comment later on frequency needs.

The Commission had proposed earlier that there be sharing between the broadcasting-satellite and communication-satellite services in the 11.7–12.2 GHz band, with the communication-satellite service limited solely to the distribution of television program material. It decided that limiting the communications-satellite service solely to the distribution of TV program material would waste spectrum space, in view of the uncertain status of the broadcast-satellite service, and removed the limitation from its proposals.

On the question of choosing an up-link to send program material to the satellite for broadcasting in another band allocated to the broadcasting-satellite service, the Commission said that since broadcasting is normally a Commission-licensed function, it had



FCC Denies Proposal To Change EXTRA CLASS Requirement

A petition by Anthony R. Gorgano requesting amendment of Sections 97.21 and 97.23 of the rules to delete the 20 wpm code requirement from the amateur Extra license examination has been denied by the Fed.

In support of his request, Mr. Gorgano argued that only 13 words per minute is required for an amateur Extra license under Article 41 of the Radio Regulations, Geneva, 1959. He contended that improvement in the amateur radio service and advancement in skills in communication are a result of new techniques and experiments such as amateur satellites, slow-scan television, facsimile and repeaters, and single sideband, and that these advancements in voice communications skills owe nothing to the ability to expertly send and receive Morse code.

The Commission said that although it agreed that the 13 wpm code requirement is adequate to comply with international regulations and that code ability is unrelated to voice communications, it would, nevertheless, continue its practice of expecting candidates for the highest class of amateur licenses to possess more than a minimum acceptable level of competency in the communicating and technical phases of the art.

Which leads one to wonder why the FCC does not require today's amateurs to be skilled in such other unrelated communications media as smoke signaling, semaphore, drum-beating, and letter writing.

When Mike Staal (K6MYL), of San Jose, California, was ordered to lower his antennas because of a normally unenforced ordinance, he applied for a variance. At a public hearing, the local planning commission denied his request.

So Mike appealed the decision and attended another hearing. His neighbors stated that his antennas "detracted from the character of the neighborhood." Under closer scrutiny, however, the neighbors were thinking beyond "character." Some complained of his antennas "causing garbled reception on TV, stereo, and radio sets."

A local newspaper reported that Mike had suggested to one woman neighbor that the interference might be attributable to inherent problems within her own electronic equipment. According to the lady, she paid $50 subsequently for "unneeded" repairs The local newspaper quoted the woman as summing up her feelings with, "He's a pest."

Mike Staal isn't standing pat just yet. He has engaged a local attorney–ham and intends to press the issue. He also has notified ARRL headquarters and requested the League's assistance. In a four-page letter to John Huntoon (League's general manager), Mike Staal capped his request for aid:

Nine times out of ten if a ham's neighbors can watch TV, and or listen to their hi-fi stereo systems in peace – what the ham does antenna-wise or otherwise is strictly ignored. I hope the League and headquarters can begin some action to change the events that are bound to occur if the present situation continues.

1970 ARRL Roanoke Division Convention

The 1970 ARRL Roanoke Division Convention will be held in Raleigh, North Carolina, sponsored by the Raleigh Amateur Radio Society. Activities will begin on Saturday, October 31 and continue through Sunday, November 1. Governor Robert W. Scott will proclaim the following week (November 1 through November 7) as Amateur Radio Week in North Carolina in recognition of the public and community service performed by licensed amateur radio operators.

The convention, almost a year in planning, will include in its program a full variety of features to hold the interests of all devotees of amateur radio as well as their XYLs. Featured speakers will be highlighted throughout the convention, during both the individual programs and at the main banquet.

On Friday, October 30 from 1600–2200 EST, a talk-in to convention headquarters will be conducted on 75 meter SSB, 6 meter SSB, and 2 meter FM. The talk-in will continue from 0800–1200 EST on Saturday, October 31 for those arriving on that day.

Activities, commencing at 1000 EST on Saturday, October 31, will include items of interest such as a DX forum (hosted by the North Carolina DX Association), MARS programs, RACES and CD programs, manufacturers presentations, NET forum, FM and repeater discussions, state-of-the-art and space communications programs, and many more. Of particular interest will be the ARRL forum attended by Vic Clark, W4KFC, our \$2.75 per person with advance banquet tickets \$8.00 per person, a total of \$10.75. Registration at the time of the convention will be \$3.00 per person and banquet tickets will be \$8.50 per person, a total of \$11.50 at the door. Due to a limited number of persons able to attend the banquet, tickets will be sold on a first come–first served basis so get your requests in early. Hotel reservations will be available for those desiring them and will be made and confirmed by the pre-registration committee on request.

Watch your mailbox for further announcements concerning one of the finest ARRL Roanoke Division conventions ever held. Plan to come to Raleigh, North Carolina's capital city, for the 1970 ARRL Roanoke Division Convention on October 31–November 1.

Trillium Weekend

November 20–21, 1970

Trillium Weekend contest will be held by The Ontario Trilliums from 0300 GMT November 21 (7:30 p.m. EST Nov. 20) thru 0300 GMT November 22, 1970.

The Trilliums being the host club will call "CQ TW." All others will call "CQ TOT."

Exchange signal report, name, QTH, and Trilliums will give their club numbers. CW and fone contacts will each count as 5 points. Low-power

Annual Indiana QSO Party

This contest, sponsored by IUPUI Amateur Radio Club, will take place from 1900 GMT Saturday December 5 to 0600 GMT December 6, and from 1600 GMT to 2400 GMT on December 6. It is open to all amateurs. Same station may be worked on different mode and different bands. The exchange will be QSO number, report and state, province or country. Indiana may work other Indiana stations. Suggested frequencies: CW, 3535, 7035, 14035, 21035, 28035; PHONE, 3955, 7265, 14295, 21395, 28600, 50400 kHz. Scoring system: Score one point for each

TELEPHONE PIONEER QSO PARTY

by W2SNJ

The Stanley S. Holmes chapter of Ham Pioneers invites all telephone pioneer ham radio operators in the United States and Canada to participate in contacting as many individual members as possible and to reach members in as many different chapters as possible.

The QSO party will start at 1900 hours GMT, Saturday, December 5, 1970, and will end at 0500 hours GMT on Monday, December 7, 1970. All bands may be used and the same station may be worked on more than one band.

Phone User: Call "CQ Telephone Pioneers."

CW User: Call "CQTP"

Score one point for signal report exchange with a Pioneer in any chapter, and one point for exchanging reports with each different chapter.

Send log extract showing date, time, station worked, chapter name and number and contact number, not later than January 5, 1971 to:

Frank J. Wojcik W2SNJ
Stanley S. Holmes Chapter
Telephone Pioneers of America
100 Central Avenue
Keaney, New Jersey 07032

Swap Shop

Monroe County Radio Communications Association announces a Swap & Shop on M-50, 4 miles west of Monroe, Mich. Oct. 11, from 10 a.m. to 4 p.m. Doors open at 8 a.m.

multiplier of 1.25 for all transmitters running 150W CW, 150W AM, 300W PEP, and under.

Each Trillium station may be contacted twice. For example; one fone contact and one CW contact (same band), or two fone contacts (different band), or two CW contacts (different band). No cross band or cross mode operation allowed. CW contacts must be made below 3.725, 7.150, and 14.100.

Logs must show: date, time in GMT, RST, band and mode, TOT number, as well as name and address and claimed score. All logs must be signed by the operator.

Nonmember with the highest score will receive a Trillium Plaque. Each participant who submits a log (one contact will qualify) will be eligible for a lucky draw.

The TOT gals will operate all frequencies and modes on 80, 40, and 20 meters during contest time. If you can't find them, check the following net controlled frequencies. There will also be a mystery station in operation. Working the mystery station will give you 10 bonus points.

Frequency	Date	Time (GMT)
3.855	Nov. 21	0300*
3.685	Nov. 21	0200**
7.240	Nov. 21	1300
7.103	Nov. 21	1430
14.280	Nov. 21	1830
14.140	Nov. 21	2000
14.035	Nov. 21	2130

*7:30 p.m. EST Nov. 20)
**9:00 p.m. EST Nov. 20

Send logs to Betty Peterson VE3ASZ, 19 Innismore Cres., Scarboro, Ontario, Canada. Logs must be postmarked not later than December 31, 1970, and received not later than January 15, 1971.

Roanoke Division Director, and league officials from headquarters.

A flea market will be conducted all day Saturday with a CW contest, a homebrew contest, and a QSL Card contest on Sunday morning.

Highlight of the convention will be the banquet to be held on Saturday night featuring a well known and very entertaining speaker. Climaxing Saturday's activities, cerimonies of the Royal Order of the Wouff Houng, the amateur secret society of the ARRL, will be held at midnight.

Latest radio gear and related equipment from several manufacturers will be on display at convention headquarters during the day Saturday.

Girls, we haven't forgotten you. The XYLs are planning a fantastic luncheon, complete with speaker and mementos of your visit, followed by a shopping spree in Raleigh's modern North Hills Shopping Center, a completely enclosed. all weather center with inside access to all stores. Transportation will be provided to and from the Shopping Center. There will be a ladies hospitality room on Saturday for your entertainment with coffee, snacks, and a presentation by Merle Norman Cosmetics. In addition, a suite of rooms has been reserved just for the girls so you can freshen up, prop up your feet, straighten your seams, etc. Cost of the luncheon and transportation for the shopping spree is $3.50 for pre-registration or $3.75 at the time of the convention.

Convention headquarters is the Statler Hilton Inn, located at 1707 Hillsborough Street in Raleigh, just a short drive from all major highways into Raleigh.

While pre-registration is scheduled to close on October 20, registrations will be available at the time of the convention. Pre-registration will be

contact and multiply by the number of states, provinces, or countries. Out of state stations use the number of different countries worked for the multiplier. Awards: Certificates will go to the first place winner in each state, province, or country and first place in Indiana counties. A special award will be given to the highest scoring station in and out of state. The mailing deadline is December 31, 1970. Send your log to Contest Chairman, Thomas J. Thamann, WA9MXG, 5013 Nowland Ave., Indianapolis, Indiana 46201. For results please include SASE.

Book Review --

The Fifth Edition of SINGLE SIDEBAND FOR THE RADIO AMATEUR has been revised to include some up-to-date theory and practice. With a great deal of new material, a new emphasis has been placed on the application of solid-state devices in sideband radio equipment.

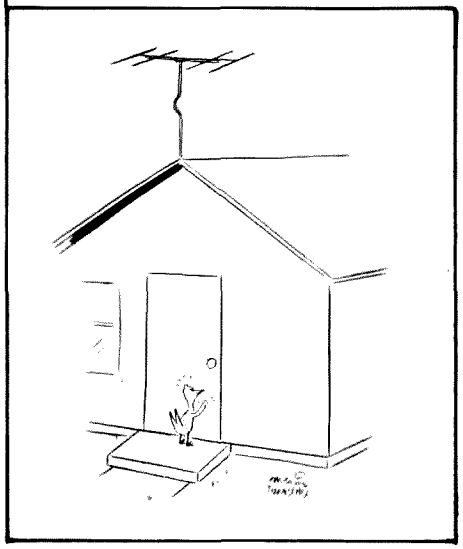
Among the thirty-odd articles (reprinted from QST) are those describing station accessories, receivers, phasing and crystal-filter SSB exciters, sideband transceivers and transverters, plus five linear amplifiers. One new entry is a solid-state transceiver covering the 80–10 meter amateur bands plus a communications receiver using phase-lock techniques.

73's evaluation: A useful book for the sincere SSB enthusiast with a penchant for building. But don't expect transistors and ICs on every page. The book is basically last year's model jazzed up with semiconductor circuits sprinkled sparsely hither and thither.

Donations $1.25 in advance, $1.50 at the door. Prizes, auction, free parking, many contests. Talk in: 146.94, 52.525, 50.4, 3.930.

RSO CONVENTION

The Windsor Amateur Radio Club will be hosting the annual Radio Society of Ontario (RSO) convention 1970 this coming October 23–24th.



Date: October 23–24, 1970 (Fri. & Sat.)

Place: Holiday Inn, Riverside Drive, Windsor, Ontario, Canada. (Across the river from Detroit, Mich.)

Registration: OM, $4; YL, $3; Students, $2.

Talk-in stations on 75 and 146.94 FM. Programs for the ladies. Door prizes. Manufacturers' displays, etc.

Tentative forums include RSO, antennas, amateur TV, FM, servicing and homebrew, RTTY, solid state, and more.

Inter-Regional Allocations Changed By FCC

Parts 2, Table of Frequency Allocations, and 97, Amateur Radio Service, have been amended to incorporate the provisions of Nos. 117 and 156, and Resolution No. 10 of the 1959 Geneva International Radio Regulations for international contacts by amateurs in the 7000–7300 kHz band. The amendments become effective October 9, 1970.

In No. 156 (Table of Frequency Allocations – 10 kHz to 40 GHz) the 7000–7100 kHz band is allocated exclusively to the amateur service on a worldwide basis. The 7100–7300 kHz band is allocated in Regions 1 and 3 to the broadcasting service and in Region 2 (Western Hemisphere) to the amateur service. No. 117 requires that stations of one service in one region must not cause harmful interference to stations of another service in the other region or regions. Resolution No. 10 provides that inter-regional amateur contacts should be only in the 7000–7100 kHz band and that administrations should make every effort to see that the broadcasting service in the 7100–7300 kHz band in Regions 1 and 3 cause no interference to the amateur service in Region 2.

In its order, the FCC listed a seven-point rule change, as follows:

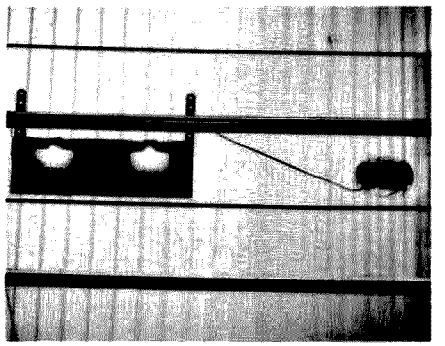
1. Among the International Radio Regulations adopted as a result of the Ordinary Administrative Radio Conference, Geneva, 1959, are Numbers 117 and 156. In No. 156, which incorporates the Table of Frequency Allocations – 10 kHz to 40 GHz, the band Regions or sub-Regions, a band of frequencies is allocated to different services having equal priority, the basic principle is the equality of right to operate. Therefore, stations of one service in one Region must operate so as not to cause harmful interference to stations of another service in the other Region or Regions.

2. Resolution No. 10 gives additional force and effect to Numbers 117 and 156, as they apply to the Amateur and Broadcasting Services. It resolves that inter-Regional amateur contacts should be only in the band 7000–7100 kHz and that administrations should make every effort to ensure that the Broadcasting Service in the band 7100–7300 kHz, in Regions 1 and 3, does not cause interference to the Amateur Service in Region 2.

3. To reflect these provisions in the Commission's Rules and Regulations, Part 2, Section 2.106, the Table of Frequency Allocations, is amended, and a new NG62 footnote is added following the Table.

4. Likewise, Section 97.61 is amended to delete the current "limitation (3)" as it now reads and to modify "limitation (4)." The new "limitation (3)" and "limitation (4)" incorporate the provisions of Numbers 117, 156, and the new footnote NG62 after the listing of the 3800–4000 kHz frequency band and after all of the listings of the 7000–7300 kHz band in the chart. Appendix 2 to Part 97 is also amended to include the text of Resolution No. 10.

CHANNELIZING MADE FREE SERVICE TO CHICAGO AREA FM HAMS



The people at Spectronics Inc., of Oak Park, Illinois, have initiated a unique little service that should prove appealing to the local 2 meter FM crowd. They have installed a well calibrated FM receiver in the store and connected two large easy-to-read meters – one to monitor deviation level and the other to indicate frequency.

They installed the meters near the front window of their store so that FM'ers can pull up in their mobiles and get accurate readouts of the two most critical transmit characteristics.

Art Housholder, manager of the firm, said the receiver in the store was always left on anyway, so why not allow it to be used by Spectronics customers as a standard?

Apparently, Spectronics' 2 meter FM customers approve of the idea, because there always seems to be a lineup of vehicles outside the window. It's kind of a drag, though, some customers complain. Parking is at a premium in the neighborhood, anyway; and local hams kind of feel guilty parking out fron and blocking the view when they're dropping in for no better reason than to buy something.

As one local puts it, "There's so many people coming and going that you really can't feel comfortable overhauling your rig out front unless you do it at 3 a.m.

Customers of Spectronics (near Chicago) can get their mobile FM units shaped up if they do it in front of the store. In the window are large meters to indicate frequency and deviation of strong signals.

7000–7100 kHz is allocated on a worldwide basis exclusively to the Amateur Service and the band 7100–7300 kHz is allocated in Regions 1 and 3 to the Broadcasting Service and that where, in adjacent

FCC Violators Get More Than Warnings

The FCC continues its crackdown on violations, and is toughening its bite, as the following actions will attest.

August 27 – JOHN W. SATTERTHWAITE, III, FAYETTEVILLE, N.C., licensee of amateur radio station WB4FOS. Ordered the license revoked, effective October 6, for repeated violation of Section 1.89 of the Rules by failing to reply to official communications (SS-302-70).

August 28 – MARTIN C. HIGGINS, LA CRESCENTA, CALIF., licensee of amateur radio station WA6AGX. Ordered the license revoked, effective October 7, for repeated violation of Section 308(b) of the Communications Act of 1934, as amended, and Section 1.89 of the Rules by failing to reply to official communications requesting information (SS-290-70).

September 3 – STEVE M. FRIED, BROOKLYN, NEW YORK, licensee of amateur radio station K2PTS. Ordered to show cause why the license should not be revoked for repeated violation of Section 1.89 of the Rules by failing to reply to official communications (SS-054-71).

GETTYSBURG OFFICE EXAMS TERMINATED

Effective September 4, 1970, amateur operator examinations will no longer be given at the FCC's Gettysburg, Pa., office. Alternate locations for examinations will be available at the Commission's offices at Balitmore, Md., Washington, D.C., and Philadelphia, Pa.

DOCTORS HONORED

At the recent annual meeting in Chicago of the Medical Amateur Radio Council, Ltd., six physician hams were awarded certificates of merit for service to the world via amateur radio.

Those honored were all MARCO members.

The Medical net meets every day on 7260 kHz at 0100 GMT, and 14.280 MHz at 0200 GMT for phone traffic, and on CW at 7060 kHz at 0230 and 14.060 MHz at 0230 GMT; the former on Mondays, the latter on Fridays.

The council is a charitable and scientific membership corporation to meet medical–electronic and radio communication needs. Its purpose is to establish personal communication among its members and their ham colleagues for dissemination of factual medical, electronics, and communication information both theoretical and practical. MARCO has members throughout the world who are either doctors of medicine, dentistry, veterinary medicine, or of other allied sciences. It also has other associate and affiliate members who are medical students, pharmacists, registered nurses, or in other allied medical professions.

First Modulated GaAs Injection Laser?

Ralph Campbell (W4KAE), of Lexington, Ky., announces that he has successfully modulated and detected an injection laser made of gallium arsenide. His equipment consists of an RCA TA-7610, whose nominal peak output is 10W operating on a wavelength of 9050 angstroms.

Pulse repetition rate was 8 kHz; transmitting optics an F/1.2 zoom projection lens, frequency modulated by voice and a Sonalert singing signal. The receiver was a United Detector Technology type PIN-6LC with CA-3035 integrated circuit (modified for video bandwidths) and a one-shot multivibrator for FM detection. Although previous range limit was 2.4 miles with a pulsed 7W (peak) unit, expected range of the newly developed equipment is up to 20 miles line-of-sight, with photomultipliers. Schottky-barrier photodiodes and FF600 fotofets are recommended for solid-state detection. Campbell is writing a book on gallium arsenide injection lasers, for publication in 1971.

Ham Auction

The Chicago Amateur Radio Club, W9CAF, will hold a ham auction on Sunday, October 25, 1970. Location is St. Viator Hall, 3608 N. Kedvale (3 p.m.). For info call CO-7-3724 or KI-5-3622.

EXPO 71

According to the latest Amateur Call Book, the number of new licenses has gone down in the past few years. The main theme of the Expo 71 exhibition will be to reawaken the interest in both the amateur in his hobby and also those of the public leaning in that direction.

Expo 71 will be a family affair, with a Kiddy Ride Park and Indian Village for the kids. A trailer camper area, and restaurant on the park site.

AMERICAN RADIO CLUB REGIONS

Charter applications have been received from several groups in response to the article on page one of the August Amateur Radio News Page of 73.

In the works are charter petitions from the following groups:

Lone Star Region (Houston, Texas)

Lincoln Trail Region (Urbana, Illinois)

Swampland Region (Metarie, Louisiana)

Gold Coast Region (Miami, Florida)

The American Radio Club will accept bids from groups of radio amateurs interested in establishing Chartered Regions of the Club. Send a list of the founding members (five or more), the area included in the Chartered Region and the name of the proposed Region to the American Radio Club, % 73 Magazine, Peterborough, N.H. 03458.

SELL: SX-100, speaker $110; Valliant $100; Apache $75; SB-10 $45. WANTED: AR-22 Rotor control. Bob Miller WA6MTY, 1377 Newport, Long Beach CA 90804.

HEATH HW-32-A, almost new; HP-13 supply, mike, and Newtronics mobile antenna — all for $110.00. Will ship: WA4TST, 507 Pinecone, Waycross GA 31501.

CHARTER JET FLIGHT to SAROC. Roundtrip New York City to Las Vegas $229.00, depart JFK 10:00 a.m. January 7th. Roundtrip Chicago to Las Vegas $199.00, depart O'Hare 12:00 noon January 7th. Return January 10th. Includes meals and drinks aloft, Flamingo Hotel Room three nights double occupancy, transportation and baggage in and out of Flamingo Hotel, dinner show, midnight show, Saturday buffet luncheon, Sunday buffet breakfast, SAROC tickets, tax and gratuity. $60.00 will confirm reservation, includes one dollar service fee. Final payment due before November 25th. Flight cancellation or written request for deposit refund will be accepted until December 1st. SAROC, Box 73, Boulder City NV 89005.

INSENSED AT INCENTIVE LICENSING? You and your club can actually do something about it. Send for free petition requesting incentive licensing apply only to ARRL members since ARRL proposed the changes. Send SASE to Committee to Preserve Amateur Radio, Box 99, Annapolis Junction MD 20701.

SALE: Pick up W2BDS "Big Bertha" plus rotator system, stacked 20m 646X, stacked 15m 532X, stacked 10m 523X, complete with phasing lines, remote controlled 8 pos. coax switch plus 40m 329X. Not everyone can afford, but — if you have desire and "mon" — come — take it away. Only $9,495.22 offered by M.D. Ercolino (201) 775-7254 before noon or (201) 531-4990 afternoon.

SB101 and **HP23A**. Factory aligned 8/69. Package with Turner 454X, bug, Heath swr bridge. Complete station, excellent condition; $275. WA2EWK, Kitchell Road, Convent NJ 07961.

SELL: Gonset G-76 transceiver 80 through 6 with ac/dc supplies, $195.00. WANTED: Collins 312B4. State price and condition. W7TMF, 1254 Heather Lane SE, Salem OR 97302.

FOR SALE CAP transceiver Heath HW-18-1 4602.5 and 4630 kHz. Assembled and tested never used. Insured and shipped for $120.00. J.D. Clowdus, Box 73, Springer OK 73458.

SUCCESSFUL HAMS invest in W6SAI Handbooks for top-man results! Cubical Quad Handbook, $3.95; Beam Antenna Handbook, $4.95; VHF Handbook, $3.95; Better Shortwave Reception, $3.95; Electronic Construction Practices, $3.95. Sold by leading ham dealers. On orders to publisher, please add 20¢ per book for handling/postage. Radio Publications, Inc., Box 149-C, Wilton CT 06897.

COLOR ORGAN KITS $7.50. IC power supplies $2.75 to $8.50. Computer grade electrolytic capacitors $.35. Xmtr transistor TRW PT3690 $2. Used variacs. Nuvistors. Catalog. Murphy, 204 Roslyn Ave., Carle Place NY 11514.

DERRICK ELECTRONICS will not be undersold on new Swan equipment. We'll beat any legitimate deal. Check around, then write. 108 East El Paso, Broken Arrow OK 74012.

WANTED! Numerous back issues of different radio magazines. Huge Free List. Trading old radio shows, airchecks, interested in commercial movie material. Thomas King, Auxier KY.

ROCHESTER, N.Y. will again be headquarters for the huge W.N.Y. Hamfest, VHF Conference and Flea Market, May 15, 1970.

Editorial:
An Old Timer Looks At The League

by George Brook Taylor W4PZS

Many of us feel deluded and disappointed in the way our hobby has been going the past few years . . .the League and its dictatorial policy toward its membership and its incompetent direction . . .the FCC for blindly accepting an injudicious proposal made by the League, that has resulted in the chopping up and cally motivated it cannot without bias represent its membership or the other U.S. amateurs in Washington.

Censorship in QST is enforced as in a military operation. Check it out. Write a clear sensible letter in opposition to one of their proposals, explain in careful detail why it will be detrimental, unworkable, or unfair. It will *never* be published! The membership has to be composed of Yes Men. If you want to get along in the League

REGENCY SCANNERS: Hi-band 8-channel $105, low-band 8-channel $109. With all accessories. Excellent condition. R. Coburn, PO Box 92, Manchester NH 03105.

SALE: Autronic keyer, key. Brand new condx; value $79.50, $19.95. Best offer by 15 November takes both. Rev. Windolph W9NHO, Quincy College, Quincy IL 62301.

RED HOT! 5RK Delta tri-bander — sensational break through in Delta Loop design. Proven outstanding DX ant. Highest quality — also heavy duty high performance quads. Check our low prices. Island Electronics, 4103 Ave. S, Galveston TX 77550.

GET YOUR "FIRST!" Memorize, study—"1970 Tests-Answers" for FCC First Class License, plus "Self-Study Ability Test." Proven. $5.00. Command, Box 26348-S, San Francisco CA 94126.

GONSETT COMMUNICATOR II for 2 meters. Asking $65.00 plus shipping. Sound electrically and physically. Edward Van Hise, 50 Gardenview Terrace, Apt. 9, Hightstown NJ 08520.

TRADE, SELL: SP-600-JX General Coverage Receiver (vfo & crystalled channels) for FM base station usable as repeater. O.C. Powell, 214 Chandler Rd., Goldsboro NC 27530.

ALLIED 5-band SSB transceiver and ac supply, A2517/2518 (reg. $450), new, only $325. R4B, new, $375. Sochor, 419 S. Euclid, Oak Park IL 60302.

BUY, TRADE, SELL: Used amateur receivers. Steven Kullmer, Evergreen Hatchery, Dysart IA 52224.

WANT TO buy or trade for 1-177 tube checker. D. Plotter, 2844 San Gabriel, Austin TX 70802.

WANTED: Receivers for 160 and 2m. Examples: Ameco All Wave Rx; Allied A-2515; etc. W2SPB, 1325 Laurel Ave., Ocean NJ 07712.

SELL: Two Synchro tape machines (Remington Typewriter/Friden Tape/Card Punch and Reader) $150. Operation instructions and manuals for Friden units only. Some tape and cards included. Complete description in late 1968 issues of 73. Tektronix 511AD $95. Tektronix 514AD $150. Manuals, probes, and some spare tubes included. Richard E. Lee, 660 Poinsettia Ave., Titusville FL 32780.

TELETYPE PICTURES FOR SALE: Volume 2, 16 pages containing 50 pictures $2.00. Volume 3 coming $1.50. Also audio and perforated tapes. W9DGV-c, 2210-30th St., Rock Island IL 61201.

NOVICE CRYSTALS: 40—15m $1.38; 80m $1.83. Free Flyer. Nat Stinnette Electronics, Umatilla FL 32784.

GREENE . . . center dipole insulator with . . .or . . .without balun . . .see November 73, page 107.

SAROC January 7—10, 1971. Flamingo Hotel Convention Center, Las Vegas, Nevada. Sponsored by Southern Nevada ARC, Inc., Box 73, Boulder City, Nevada. Advance registration $14.50 per person accepted until January 4, regular registration at door, includes Flamingo Hotel Late Show and drinks, Sunday breakfast, cocktail parties, technical seminars and meetings, ARRL, DX, FM, MARS, QCWA, WCARS-7255, WPSS-3952, and WSSBA. Ladies Program. Flamingo Hotel SAROC room rate $12.00 plus room tax, per night, single or double occupancy January 3 thru 12, 1971. Mail accommodations request to Flamingo Hotel. Mail advance registration to SAROC. W7PRM, Club President, SAROC Convention Chairman.

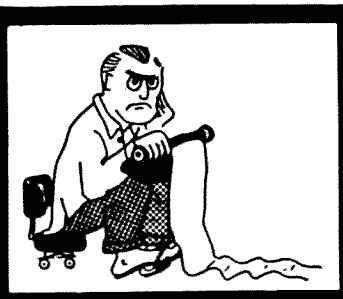
DTL INTEGRATED CIRCUITS: Guaranteed new — gates 70¢, buffers 80¢, F/F 90¢, dual F/F $1.15. Add 20¢ for postage. Also other inexpensive parts. Lists & prices from Mitch-Lan Electronics Co., Dept. 1170, PO Box 4822, Panorama City CA 91412.

butchering of our already overcrowded bands. Yet, even with such catastrophic events we still have a wonderful hobby.

Much is heard today about the lack of growth of amateur radio. Incentive licensing undoubtedly accounts for this condition. After the League started this fiasco and caused widespread dissension in the amateur ranks, the hobby began to lose favor and attractiveness to the newcomer and many an oldtimer quit in disgust.

The FCC has proved by its actions it knows little about the amateur and his problems and cares even less. The amateur is indeed a second-class citizen as far as the FCC is concerned. Several independent polls showed amateurs to be overwhelmingly against incentive licensing. The FCC received thousands of protest letters that did not adhere to their 14 copy rule. The 14 copy rule may be necessary and correct for the application for a formal rule change. It should *not* apply to all correspondence, such as an expression of views by the individual licensee to the FCC. These should be given full consideration. Obviously they were ignored. This 14 copy FCC red tape should be cut.

A quarter of a million licensees should have representation on the FCC board. The FCC should revoke incentive licensing immediately. It is an unnecessary expense to the heavily overburdened taxpayer. It is wasteful use of the time of the FCC examiners when its *only* accomplishment is to inflate the ego of the licensee.



The League has proved its ineffectiveness to the U.S. amateurs in its refusal to open a Washington bureau and register as a lobby. We know the reason – they are afraid they may lose some of their government tax and mailing privileges they now unjustly enjoy. The League is so politi- you do what you are told.

Vote a good regional director into office. He starts making noise, adding up figures, asking embarrassing questions, opening closed doors, and he soon finds himself on the outside. You hear about the secret prior meetings, the demands, the deals, the instructions to the directors.

A few years ago the League made much about what a big annual million-dollar operation their publishing business had become; then a few months later, when they decided to solicit contributions and gifts for their new building, they suddenly became the poor-boy, never again was their big business mentioned or a financial report printed on their pages. You did find many bouquets, sweet bouquets scattered throughout telling how wonderful is the League. They harp endlessly how everyone that is not a member or a contributor to the building fund is a free-loader. The *League* is the *real* free-loader. They have been free-loading their writers and the U.S. taxpayers for years.

The League should *reform*, have its house thoroughly cleaned, and free itself of government subsidies and special benefits. Only then can it properly function and be a democratic organization fit to properly represent the U.S. amateur radio operators.

Until 1964 I wore my ARRL lapel pin with pride; but after that I became so ashamed of the League I removed it. To show the League my disgust for several years when I sent in my annual dues I asked for it to be a subscription to the magazine only as I no longer desired membership. Finally, in October 1967 when the FCC gratified the League by enacting the incentive licensing thing, that was for me the death certificate of the ARRL and QST.

NEVER SAY DIE

...de W2NSD/1

EDITORIAL BY WAYNE GREEN

In this day of women's liberation movements perhaps we should examine our attitude toward our wives. Perhaps not. As long as they hold their jobs, bring home enough money to help buy a new rig now and then, bring the meals into the shack between schedules and don't plan nights out during contests, maybe we should agree with them.

A woman is as good at some jobs as a man any day. She is better at many. And if she is as good, why shouldn't she be paid just as much. Particularly if she is your wife.

Of course if you are the employer, then your perspective may be biased and you may have a poor attitude toward the argument. Employers tend to cloud the basic issues with irrelevant factors in order to justify their own greed or even their own subconscious wish to dominate women.

For instance some employers will plead that it takes an employee about six months on the job, man or woman, before they know their work well enough to function efficiently. The six month training period can cost the employer plenty as the result of errors. One wrong ad in a magazine and $400 to $600 goes down the tubes . . . or more if the advertiser cancels $6000 worth of ads as a result. The employee is sorry and promises to do better.

Once trained, what are the differences between a man and a woman on the same job? Very little in many cases. Lots in others. The employer has nothing whatever to worry about as long as the woman has no children who can get sick and need care, has a husband that is not going to get a job elsewhere, and does not get pregnant.

You may find this hard to believe, but I personally know of a publisher in New Hampshire who has a women's lib wife and pays man-type salaries to his women employees. So far this year three of his highest paid employees, girls that he trained for many months, left the state because their husbands moved. This is a poor example of company loyalty, admittedly, for the employer is out who knows how many thousands of dollars. If he'd hired men for the jobs they might still be there. The publisher is left wondering whether the equal pay policy isn't awfully one-sided.

Is the solution unmarried girls? Not on your buttonhook, these gals will get married at the drop of a proposal to the first bum that offers to rescue them from that miserable sweatshop where they while away their coffeebreaks, extended lunches, and rest periods. Seriously, though, many gals do bring the same sense of dedication and enthusiasm to their work as a man, even though they may realize that their true goal is bringing up their family and keeping it happy.

Women's lib will get a big shot in the arm when the girls can come up with reasonable answers for those misguided employers who figure that women should be paid less because they bring in less in the long run. Should men stay home with the sick children half of the time? Should men change their jobs if the wife gets a better job in another city? Should we start working hard on some practical system for the men to have the babies, thus freeing women from morning sickness and the delivery room? Or perhaps we are getting ready to go back to the old system where the woman stops work for a few minutes, has her baby, and goes back to work. Are we mollycoddling our women too much with this free vacation in the hospital arrangement?

Hear! Hear!

One nice thing about driving in Europe is that you don't have to keep one eye always peeled for the fuzz. In the U.S., where speed limit signs are everywhere and the limits proclaimed often impractical and ignored, it behooves the driver to watch for radar, hidden patrol cars, and such.

My mind has been greatly eased by a new book, "Take Your Traffic Ticket To Court – And Win!" This book, written by a retired judge, should enable anyone to win just about any traffic ticket case. Why line up at the cashier's window and pay that fine? Do you take it for granted that the police always correctly interpret the vehicle code? Do you pay the fine to save time and trouble even when you know you're really not guilty? If you're shelling out more and enjoying it less, this book will help you to insure your legal rights.

Leaky Lines

AN EDITORIAL by DAVE MANN K2AGZ

1 DANIEL LANE, KINNELON NJ 07405

At first blush the "Hobby Class" license proposed in July's issue of 73 excited resistance on my part. I felt, as do many others, that we ought not to favor any class of license which would not have an accompanying hurdle of code and theory attached to it, so that there would be some means by which the unfit or otherwise unacceptable might be weeded out. And then I got to thinking seriously about it . . . I mean objectively; weighing the alternatives; trying to envision the results which might come about as a result. Although I would not have liked to admit it at first, I now feel constrained to state that I have changed my mind concerning the subject. And I will tell you why.

Recent actions relating to the amateur service do not indicate any marked inclination on the part of FCC to consider our problems as seriously as it considers its own. Their principal action, which was supposedly implemented for the best interests of amateur radio, that is, incentive licensing, was brought about as a result of ARRL suggestions. The change did not originate with the Commission. Or, if it did, way back in the past, it was kept alive by ARRL, which the FCC regards as the spokesman for all hams. Most of their other actions; creation of Citizens Band, raising fees for licenses and renewals . . . these and others are indicative of the fact that we are hardly at the top of FCC's list of priorities. We have sometimes noticed an apparent unwillingness to crack down hard on violators of FCC regulations who happen to be nonhams, particularly CB'ers and commercial intruders into our spectrum. Such persistent flouters of the laws have not only gotten away with their illegalities, they continue unabated.

It is clear that the FCC, understaffed and underfunded, is far too busy with commercial radio, television, telephone, communications satellites, radioteletype, wire services, and others, to be able to devote themselves more than casually to the ham bands. That is why we must continue our policy of self-policing. That is why we must devise and suggest the changes that will improve our condition in the scheme of things. If the Commission, sometimes all too prone to reject wise suggestions in favor of unwise ones, is too busy and harassed to find avenues for our growth, then we ourselves must do so.

The effects of the presently constituted Citizen Band allocation are too well known to have to be recapitulated here. Those for whom this service was originally created have not been able to make full use of it, due to excessive misuse by hobby-oriented persons seeking an outlet for their repressed energies, but unwilling to devote any study or thought to obtaining amateur licenses. There have been some efforts among the CB'ers themselves to halt this travesty . . . to build a nationwide organization similar to ARRL, so that all quasi-ham activities in CB . . . civil defense, fire watch, road patrolling, small boat safety, etc., might be coordinated in a constructive fashion. They are aware that this is the only way in which a program of self-policing, such as our own, can minimize the numbers of inveterate violators in their ranks. These efforts have not been notably successful. To be sure, there are clubs and associations, such as REACT, which are currently trying. But the deliberate violators constitute such a staggering percentage, that it is unrealistic to expect REACT and others to be sufficiently broad-based that a significant dent can be made.

In many instances we amateurs are blamed for interference which originates with this illegal CB operation. We have had to face indignant neighbors, demanding a cessation of our legitimate activity, when the true culprits have been local CB hobbyists. Since we are visible in our communities, operating openly, and since TV repairmen are notorious sometimes for attributing reception difficulties to the "ham with the big antenna tower in the next block," the problems continue unabated, and we must constantly deal with repeated efforts to limit amateur radio, while the 27 MHz lunacy goes on and on and on, like a communicable disease, unchecked.

The creation of this hobby license would effectively lessen these irritating conditions. It would open a viable source of income to the manufacturers of radio equipment, and would undoubtedly result in higher pay envelopes for many of the hams who are employed in the electronics industry. It would provide a large source of additional revenue to the FCC. It would assist greatly in the development of new VHF techniques. It would liberate 27 MHz for the legitimate use of those whose livelihood may

(cont. on page 96)

Death of a Rig

We should be ashamed. All of us. The ham fraternity has collectively brought sufficient pressure to bear on one of our most reputable manufacturers that a fresh and necessary unit of exceptional design was dropped. The manufacturer – Swan Electronics – will lose money because of tooling and design expenses that will never be recouped. The amateurs lose because they'll not get the benefit of a truly great transceiver design approach. And all because a few ham do-gooders jumped to some irrational conclusions.

But let me start from the beginning: Engineering thinkers at Swan had noted the lack of activity on 10 meters and put their heads together to see what they could do about it. Here's what they learned: When 10 meters is open for comparatively long periods, the band gets progressively more populated.

It seems obvious that amateurs enjoy working 10 meters, but not many people monitor enough to know when the band is open and when it is not. As a consequence, many openings come and go witnout hams around to take advantage of them. What 10 meters needs, Swan said, is a surefire and quick method of knowing when 10 is usable for DX.

One excellent solution was the one adopted by Swan – simply incorporate an 11-meter receive capability in a 10-meter transceiver. With all the nearly constant signals on the 11-meter CB channels, an opening could be detected there almost instantly. Then the operator need but fire up the 10-meter transmitter (which won't work on 11, by the way) and put out a call.

With enough hams using the system, everyone benefits: 10 gets active, openings no longer go unnoticed, and another dying band gains renewed popularity.

A good idea? At 73, we thought so. But there were a handful of loudmouths who didn't. They wrote to Swan. They wrote to the FCC. They wrote to the ham journals, including 73, where their comments were filed where they belong – in the wastebasket.

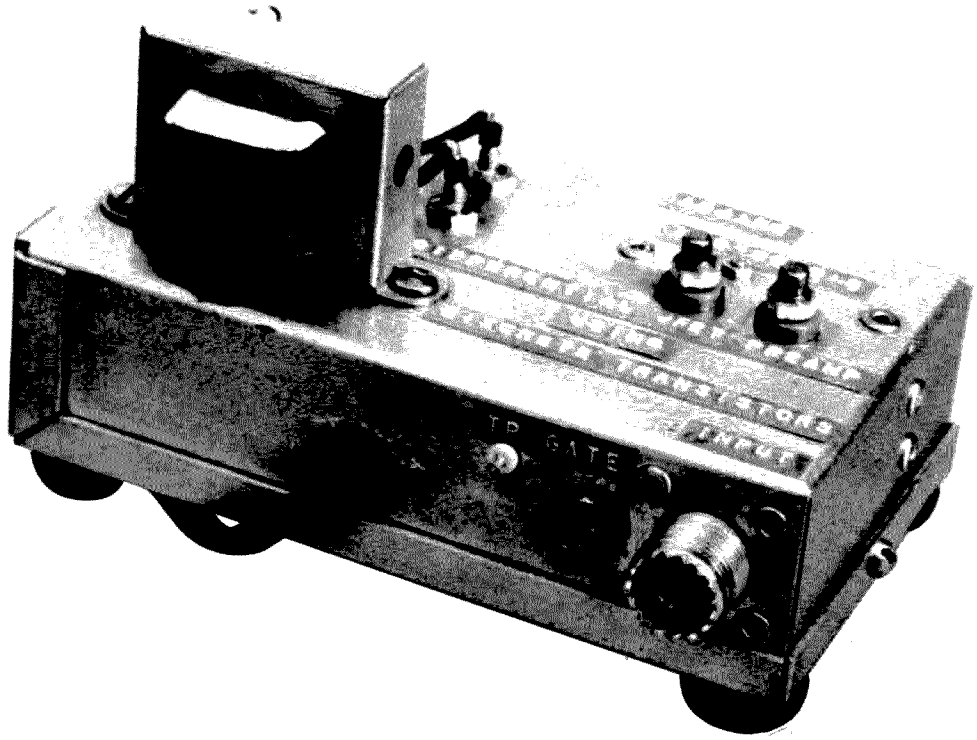
Their complaint? Swan's new transceiver (No. 1011) can transmit and receive on 10 meters, but they feel its "receive only" capability for 11 meters would encourage CB'ers to buy and modify for illegal operation on the CB channels.

It apparently didn't occur to the whiners that any linear that will operate on 10 will operate on 11 meters; that many manufacturers – including a few "respectable" ham manufacturers are actually building and selling high-power linears *exclusively for* the CB channels. They didn't take note of the fact that virtually any transceiver that operates on 10 can be made to operate on 11. Such facts eluded them. All they could see was an 11-meter receive capability built into a 10-meter transceiver – and that was enough to get them going.

As editor of 73, I'd like to put in my two cents worth: First, the ham radio field is not a lucrative market. Manufacturers are – as often as not – in this aspect of the business because of personal management ties to amateur radio. Partially for this reason we amateurs should do our best to encourage and support these manufacturers (whose profit margins are far too narrow considering the engineering, development, and marketing efforts that must be expended for every item produced).

Second, I consider it blue-sky speculation for any amateur or group to assume that any manufacturer's products are going to be used for any purpose other than that for which they were designed. Take the case of the Swan 1011, for example. There seems to be three possible misapplications: (1) CB'ers could conceivably buy the transceiver and modify it for 11-meter transmit operation; (2) CB'ers could conceivably buy the unit and use it for illegal operation on 10 meters; (3) hams could buy it and use it for unlicensed operation on 11 meters.

From my experience in the CB field (I am also editor of a national CB magazine), I feel it is safe to say that not one CB'er in two hundred has the technical capability to successfully complete the necessary transmitter modifications – which takes care of item (1).



As far as item (2) is concerned, I believe that there aren't many CB'ers who are interested in joining us hams on 10 meters. I see every action notice that follows up an FCC violation, and do not remember a single case in the past 10 months where a CB'er has been nailed for operating on the ham band. Some CB'ers operate DX illegally; some use "skip" names instead of assigned calls; some run high power; some ragchew illegally; some have unlawful antenna setups. But there is no indication that any of them are infiltrating the ham bands.

Item (3) should speak for itself; how many amateurs do you know who would go out of their way to bootleg on CB? Enough said.

But the damage has been done. Swan only recently announced the 1011 addition to its line. Now, just weeks later, the addition is canceled. Swan's letter to ham dealers reads:

> For the first time in our history we have introduced a new model transceiver that has met with the disapproval of a number of our radio amateur customers. Letters we have received indicate a serious concern that the 1011 will be operated on the 10 meter band by CB'ers or other unlicensed

(cont. on page 97)

DIFFERENTIAL J-FET PREAMPLIFIER

Ralph W. Campbell W4KAE
316 Mariemont Drive
Lexington KY 40505

How about trying a J-FET (usually pronounced "jay-fet") preamplifier using discrete transistors, in the *differential* configuration? "Differential" is circuitry best known through work with integrated circuits; but there is no reason why we can't use "discretes" to achieve the results we seek. The amplifier presented here is the result of searching through various amateur and professional publications for the lowest-noise solid-state circuit – revealing little "new" – except for this mode of operation.

I turned to RCA's IC-41 linear integrated circuit manual for comparison of various bipolar IC hookups; the RCA CA-3028 looked most interesting, so I then chose Motorola's MFE-2000 as a discrete J-FET replacement. The RCA CA-3028 boasted 0.5 dB better noise figure in the differential mode, as compared with the cascode circuit. Hopefully, a similar "edge" in performance should exist with the J-FETs. The interesting thing about this new circuitry is that one semiconductor is in an "idling" position, while the other device does the amplifying! This results in two advantages: (1) The high-gain transistor (which may oscillate) can be made the

idler; or even a lower-gain, cheaper J-FET with the same noise figure can be plugged in; and (2) noise reduction with balanced, push-pull input, is achieved. Junction field-effect transistors (J-FETs) have further advantages, such as superior resistance to overloading, wide dynamic range with the higher drain voltages, and ease of input matching.

With exception of low-noise multiple devices (two J-FETs diffused on a single chip) these discrete transistors solved noise problems readily apparent to the ear. After listening tests, the 2 meter noise reduction seems about 1 dB; however, as to actual noise figure (not with the gain provided), I would assume only 0.5 dB to be the real improvement.

Another advantage with the differential mode is that neutralization requirements are greatly reduced. A tee section decoupler stopped all tendency for oscillation, even when higher-gain MFE-2001s were substituted. With a spot noise figure of 1.6 dB typical, we have a great 2 meter preamplifier! While I don't do more than estimate noise figure and gain, it is true that attempts were made to use University of Kentucky measuring equipment, but it was not operational.

Theory

Design of the preamplifier is straightforward. Dc biasing is just like vacuum tubes, except the supply voltage is much lower. I followed WIDTY's *Field Effect Transistor Primer*, (73 Magazine, Dec. 1965), and I must admit both "experimenter" and "paper" design techniques were applied. To get going on the "paper" design, I used the normalized FET transfer curve presented in that article, and referred to Motorola's *Semiconductor Data Book*, 3rd Edition, to determine pinchoff voltage V_P. Values given are 4.0V for V_P and 10 mA for I_{DSS}. With regard to Fig. 1, 10 mA and 6 mA are marked on the vertical axis for values of I_D; and the 0.6 ratio point is selected as described below. In case you've guessed 6 mA is the operating drain current!

Gate-to-source voltage is normalized or divided as with I_{DDS} and, since we have I_{DDS} set to be 10 mA and V_P at 4.0V, the loadline can be determined by dividing 4V by 10 mA, which works out to be 0.4 in normalized kilohms. The reason for using kilohms is that this saves time; and to check this scale plotting factor, simply extend the R_S=1 kΩ line until it intersects the upper right-hand coordinates.

The unknown ratios are now found. This is so easy that I used the "unknown" I_D/I_{DDS} ratio (above) by accident. Since we know the load line is to be 400Ω, it is drawn between the 300Ω and 500Ω lines already present on Fig. 1. (For clarity, I've extended the 400Ω line beyond the upper horizontal axis.) Now, where this line intersects the transfer curve (running parameter) we see a vertical and horizontal intercept at the 0.6 and 0.24 points for our ratios of I_D/I_{DSS} and V_{GS}/V_P, respectively. The use of this information can help the designer choose the operating point for any values up to 30 mA or 25V with the Motorola MFE-2000.

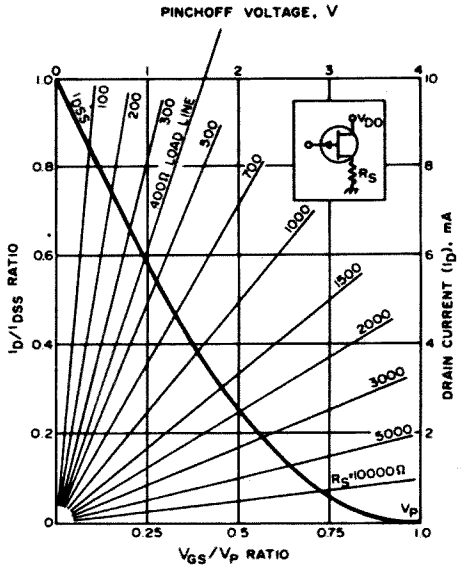


Fig. 1. Normalized FET transfer curves with typical operating parameters. Coils are: L1—2t 18 AWG, ¼ in. dia; L2—12t ct 18 AWG, ¼ in. dia; L3—10T 18 AWG bore, 3/16 in. dia; L4—2t 18 AWG (interwound), 3/16 in. dia.

Measurements

The operating point voltage was measured to be −1.2V, and operating

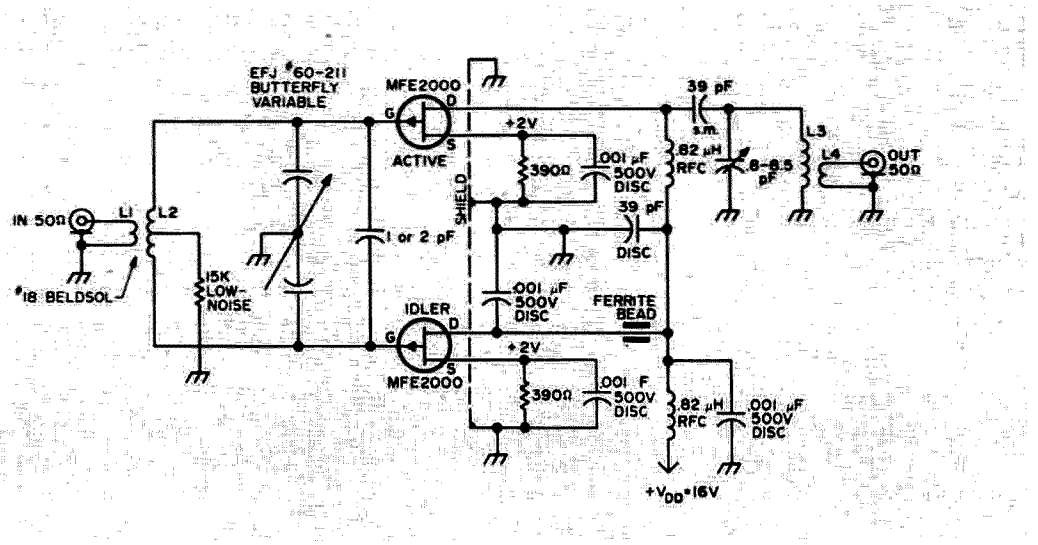

Fig. 2. Low noise J-Fet preamplifier for 2 meters.

current was measured at 5.5 mA. Gain of the J-FET differential preamplifier was found to be 3 S-units.

Choosing the gate-leak resistor was a matter of consulting the literature, where I found a circuit using TIS-88s (similar to 2N4416), which had a 27 kΩ gate return resistor. Having two MFE-2000s, I took about half-value for this resistance for both transistors operating in parallel.

Construction

The lead photo shows the top view of the differential J-FET preamplifier whose circuit appears in Fig. 2. This unit is built within an LMB 531EL endlock aluminum chassis. Note that each capacitor there is a large Ferroxcube ferrite bead (56-590-3B), which prevents man-made noise from entering the enclosure. The standoff on the side of the enclosure is the test point for drain-to-ground voltage checks. "Pop" rivets are seen in their use as interunit shield fasteners for the partition inside.

For the preamp, I used a 0.8–8.5 pF gold-plated piston capacitor. (The piston trimmer is shown in the closeups.) Other types of pistons having the same capacity and capacity range would work as well; however, the gold plating probably improves resettability and lowers rf surface ground losses.

Between the glass tank circuit and shield partition is the tee decoupling network, which is dc fed from the voltage doubler power supply. The common leg of the tee is resting on a 240 pF button bypass (value not critical), while to the right and left are the Miller molded, shielded 9240-707 rf chokes.

A feedthrough fitting is connected through the partition wall of the internal shield to the right-hand (single) drain connection; and the 39 pF silver-mica blocking capacitor rests against the chassis end plate. The shield partition tongue is bent to fit, and soldered onto the body of the partition. This makes a firm contact with the preamp bottom cover, when in place.

To the upper left of the shield is a piece of RG-174/U coaxial cable which connects to the test point.

A tubular ceramic capacitor across the variable capacitor (see closeup photo) provides signal resonance at the unmeshed position. The insures minimum noise characteristics, through the tuning range. The fixed capacitor should be to have a value within the operating range of the variable. This technique, by the way, also prevents false noise dips or peaks.

The power supply (Fig. 3) is a conventional full-wave voltage doubler with a trimming and surge resistor in series with the 6.3V secondary. Drain-to-source volt-

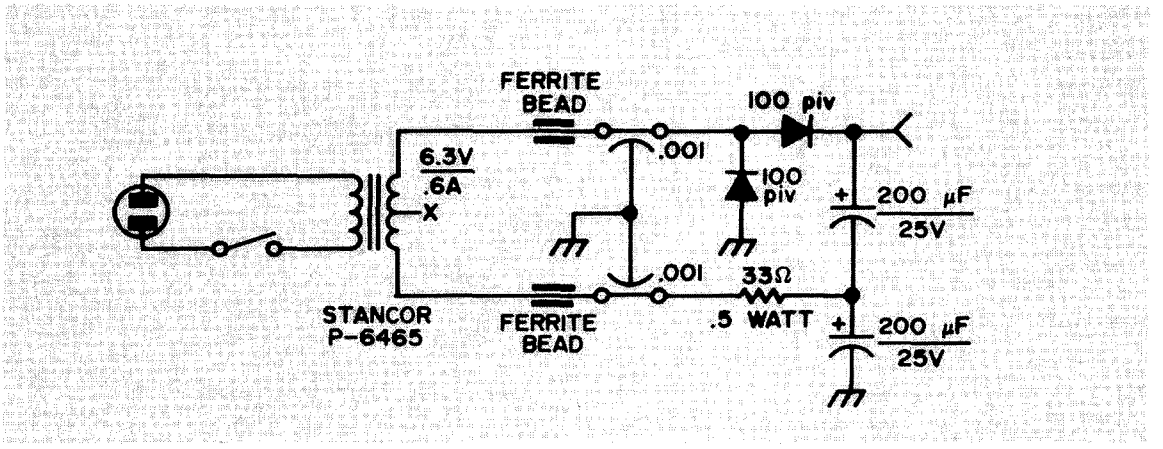

Fig. 3. Power Supply.

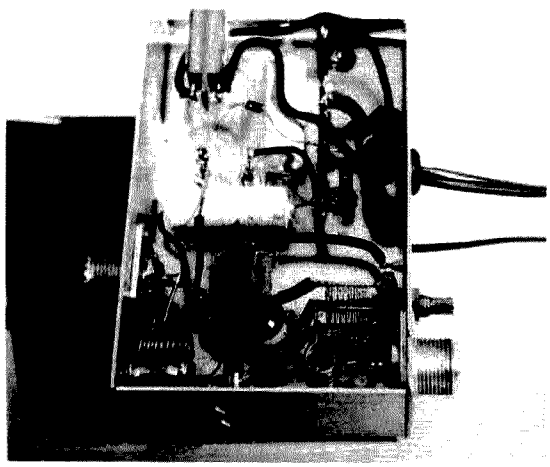
age "trimming" of the power supply is done with this surge resistor. Use of the tee should completely eliminate all oscillation.

Alignment & Adjustment

Noise figure estimating is always a curious business, since the variables involved depend upon usually inaccurate assumptions about generator impedance, signal level, and transmission line matching. One big problem was how to find a signal or noise dip. With a balanced differential input I found either a pair of dips at either end of the butterfly tuning range or a pair of peaks at these range ends. Between, I observed either a small peak or small dip, depending upon signal levels being fed to the preamp.

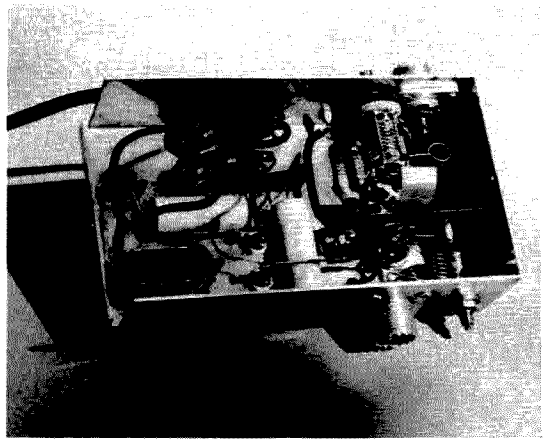


Before dipping and peaking adjustments were made, I used a Heathkit tunnel-dipper to place resonance at 144 MHz. This was with the input variable at the minimum capacity setting, the J-FETs in their sockets, drain and gate bias voltages present, and with the output piston capacitor adjusted for maximum capacity. Under these conditions, I realized the next thing to do was to load the balanced input tank circuit with 1–2 pF to keep the actual tuning range *below* resonance at signal frequencies, since lowest noise figure is always obtained this way. Strong signals (milliwatts) from my International Crystal 2 meter frequency standard resulted in two peaks at either end of the butterfly range, with a small dip in between. What this meant was that the J-FETs were absorbing several milliwatts of power at the crystal standard frequency, behaving like a generator and a load with the coaxial line voltage dropping between range-end peaks as conditions of maximum-power-transfer were approached. This doesn't mean the front-end input terminal was purely a resistance: The front end is probably matched to the resistance and reactance present; but the resistive condition, alone, is the load seen by the balanced tank circuit looking into the gate terminals. This procedure is the "strong-signal" method of obtaining lowest noise figure in the differential mode. Now here's another:

Most amateurs probably don't have a safe strong-signal source; so the weak-signal method is offered as an alternative. Using the Ameco TX-62 exciter, I found I could set the drive to minimum and, with the spotting switch, found it to be possible to send a weak signal (microwatts) into the differential J-FET preamplifier for noise adjustments. Of course, it is desirable to have the input fed from a terminated coaxial connector capacitively coupled through the open contacts of a Dow-Key SPDT relay. The termination used was a shielded CesCo PL-52 CB radio 5W dummy load. With the termination switched in and the desired weak signal from the Ameco exciter, I adjusted the capacitor for a peak between the two range-end dips. Confirming this as the low-noise point is easily checked by switching back and forth from dummy load to antenna (during a period of minimum band activity).

An explanation of circuit conditions would probably show that peaking occurred at the microwatt level, with the highly reactive generator coupling making the weak-signal source impedance appear very high. This would make any response other than resistive (matched at the gate terminals) immeasurable.

Operation



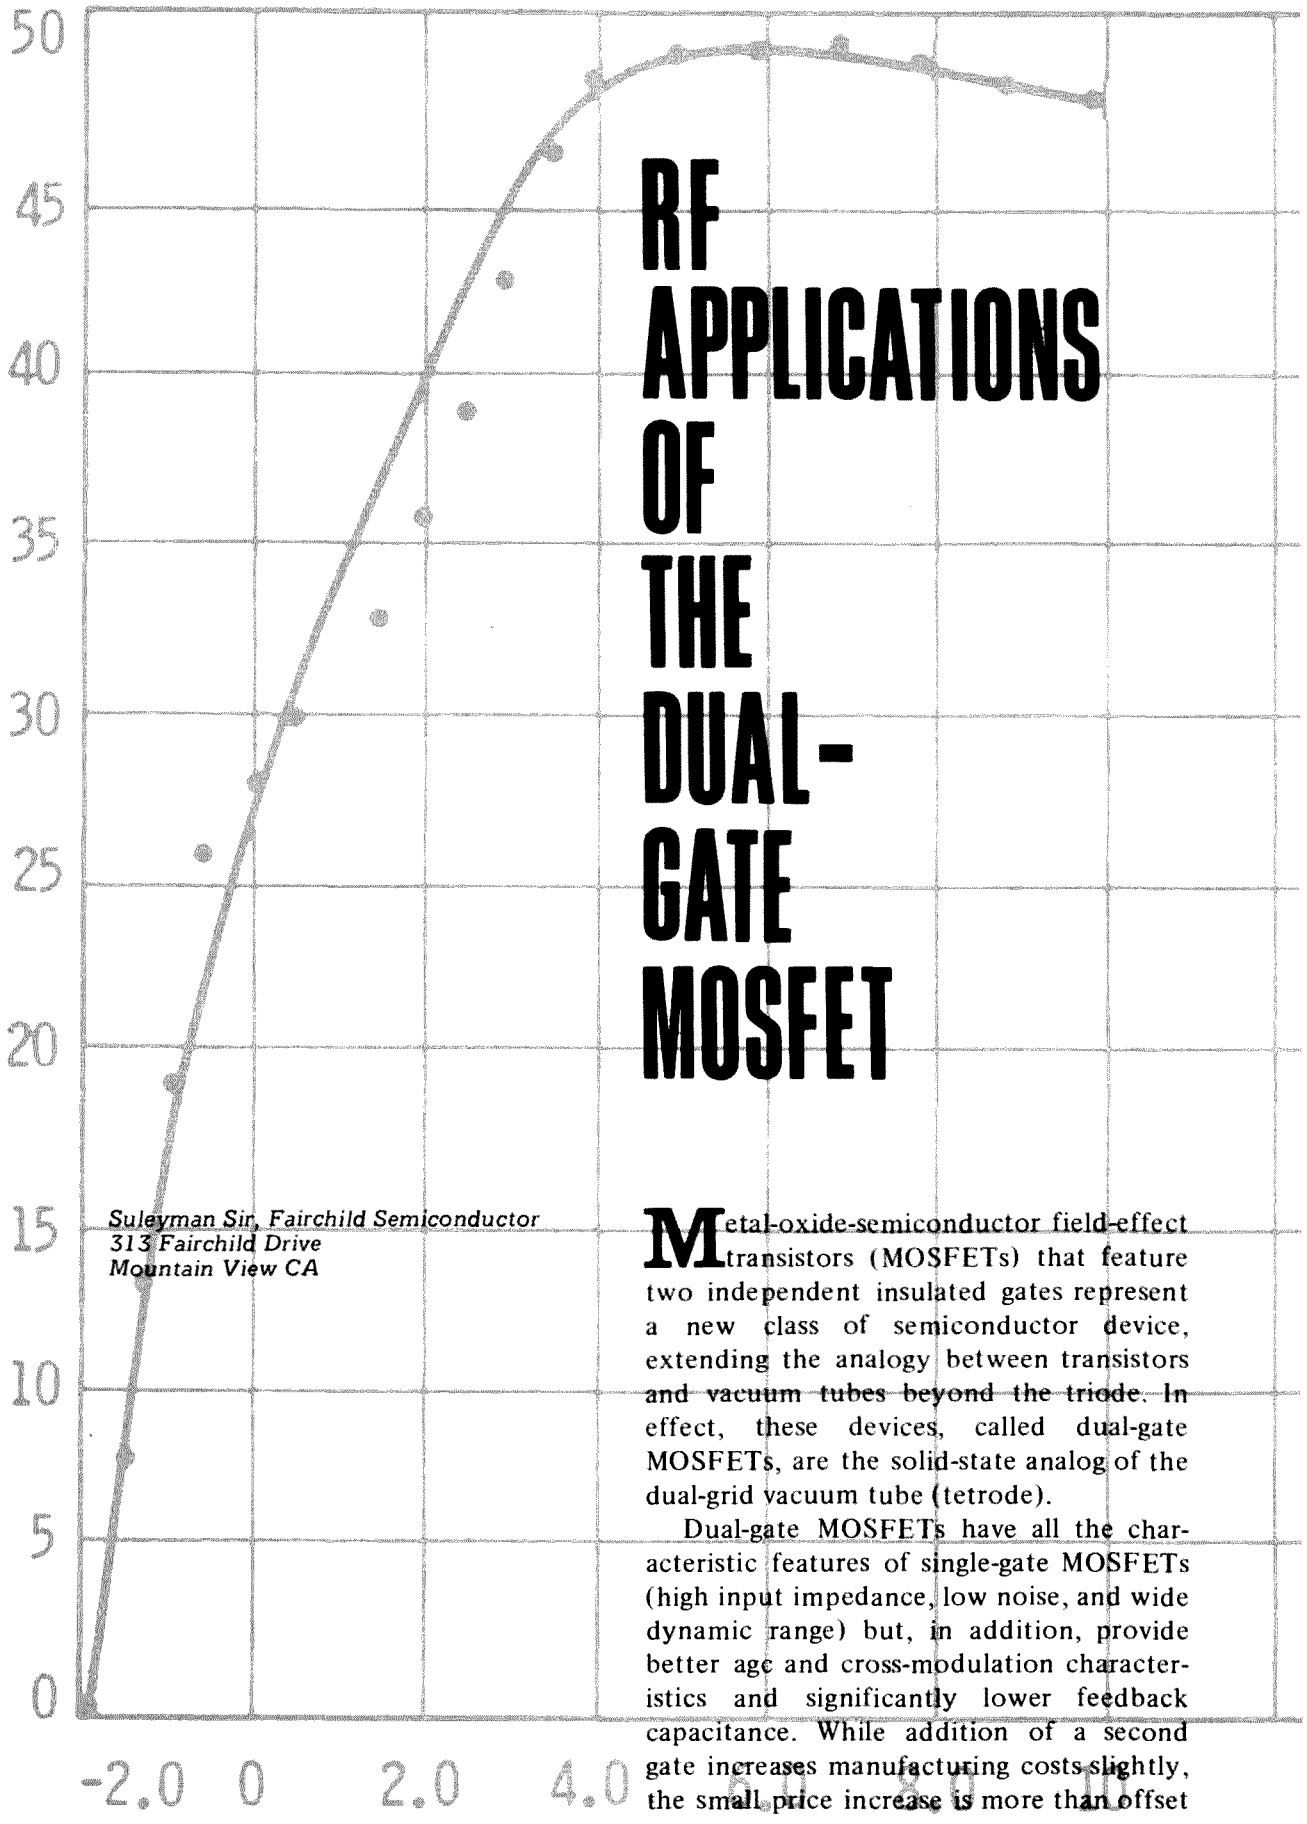
The differential J-FET preamplifier has been a pleasure to use. Not even locals overload my receiving equipment and the noise figure is so low I can hear transmission line noise (observed on incoming signals with separate antennas of about the same gain) when comparing RG-9 or RG-8 with a similar length of Aluminum Foamflex cable. I might add that without the

low-noise line, little can be achieved in "system" noise reduction, when dealing with the ever-present thermal agitation noise prevalent in most VHF gear.

The MFE-2000 J-FETs by Motorola showed very little tendency to oscillate using the differential amplifier configuration. I tried MFE-2001s, a higher-gain version, which did oscillate with one transistor of the pair chosen; however, the noise figure appeared to be the same.

Only one transistor is fully operative in the differential mode: but if you think the noise doesn't go up upon removal of the idling J-FET, just try removing it on a weak signal! Even a quick retune with a

single active FET will show more noise than with two.



Use of the transfer curve brought out so clearly in W1DTY's primer should find extensive application in "power" FET work: For one thing, the normalized character of the curve can be altered to fit any device (including FETs like the CP-650 and CP-651, by Crystalonics) for operation in the power-gate region. For another, the curve can be force-fitted to suit both depletion and enhancement modes.

Conclusion

Regardless of how accurate a "paper" design is, always test the unit thoroughly in the laboratory before reconciling results with it. The "experimenter" method is always a valid check. Before building the unit described in this article, make sure you're using low-noise coax such as Amphenol 21-539 or Communications Products Aluminum Foamflex, or a very short length of the regular kind. The reason is that without the feedline having this characteristic, chances are you will not be able to notice "less noise" on incoming DX signals.

I would encourage others to try their hands at FET designs similar to this. And don't forget: If your receiving equipment doesn't use at least one three-lead semiconductor device in the first stages – it may be obsolete!

RF APPLICATIONS OF THE DUAL-GATE MOSFET

Suleyman Sir, Fairchild Semiconductor
313 Fairchild Drive
Mountain View CA

Metal-oxide-semiconductor field-effect transistors (MOSFETs) that feature two independent insulated gates represent a new class of semiconductor device, extending the analogy between transistors and vacuum tubes beyond the triode. In effect, these devices, called dual-gate MOSFETs, are the solid-state analog of the dual-grid vacuum tube (tetrode).

Dual-gate MOSFETs have all the characteristic features of single-gate MOSFETs (high input impedance, low noise, and wide dynamic range) but, in addition, provide better agc and cross-modulation characteristics and significantly lower feedback capacitance. While addition of a second gate increases manufacturing costs slightly, the small price increase is more than offset

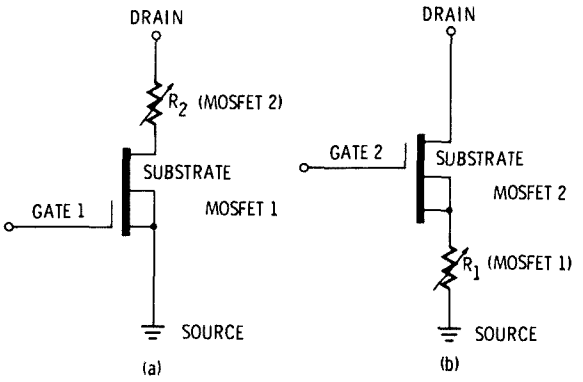

Fig. 1. Two equivalent MOSFET circuits to show signal injection at (a) gate 1 and (b) gate 2.

by eliminating the need for some components normally required in conventional MOSFET circuits.

The special characteristics of dual-gate MOSFETs make these devices ideal as UHF, VHF, and FM amplifiers, VHF and FM mixers, and i-f amplifiers.

Circuit Performance

Dual-gate MOSFETs, like other FETs and bipolar transistors, are used for signal amplification. The signal can be injected at either of the two gates, but normally gate 1 is used for signal injection and gate 2 for gain control. This preference can be explained by analyzing the two alternative equivalent MOSFET circuits shown in Fig. 1. Figure 1a shows the equivalent circuit with signal applied to gate 1, and gate 2 ac-grounded. In this mode, when the dc bias of gate 2 is changed, MOSFET 2 acts as a variable-load resistor on MOSFET 1, representing a gain change.

By contrast, Fig. 1b shows the equivalent circuit with signal applied to gate 2, and gate 1 ac-grounded. In this mode, gate 1 is used for gain control and MOSFET 1 acts as a series source resistor. As the dc bias voltage on gate 1 is changed, the value of the source resistor will increase or decrease, and gain control is accomplished. However, this mode of operation results in lower gain because of the degenerative series resistor, and since gate 2 is closer to the drain, the feedback capacitance is higher compared with the other mode of operation.

When the device is operated as shown in Fig. 1a, the MOSFET is analogous to the common-cathode, common-grid cascode tube amplifier used for high degree of isolation between input and output stages.

Dual-gate MOSFETs have the following advantages over the triode MOSFETs.

- Low feedback (reverse-transfer) capacitance, which allows the device to operate as a very stable amplifier.
- Excellent agc performance with an agc range of approximately 50 dB. This characteristic makes the device ideal for use in front-end applications. The agc range of Fairchild's FT0601 is shown in Fig. 2.

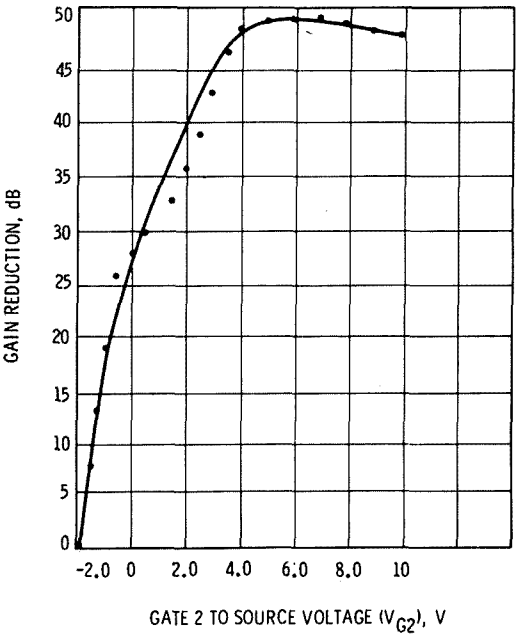

Fig. 2. Agc performance of the FT0601 (V_D = 15V, F = 200 MHz).

- Good cross-modulation performance. Dual-gate MOSFETs have square-law transfer characteristics; therefore, they are suitable for amplifiers that require minimum cross-modulation distortion.
- Uniform and fixed input and output conductances, which do not change greatly with the agc voltage. This can be seen in Fig. 3, which shows the

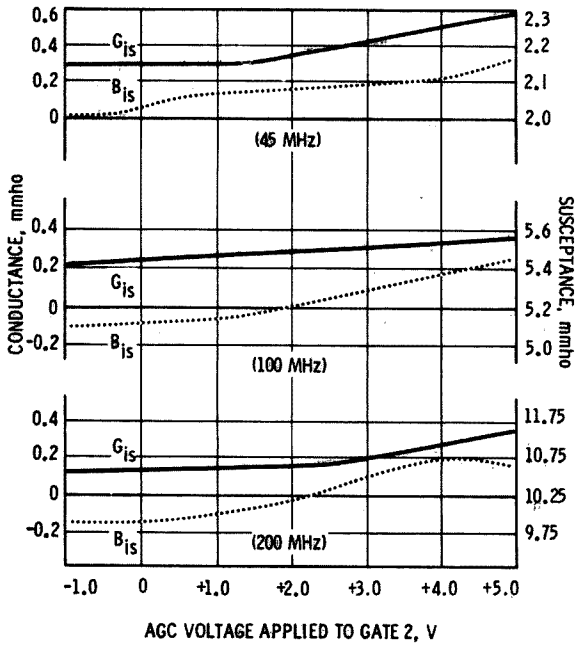

Fig. 3. Admittances of the FT0601 as a function of agc voltage.

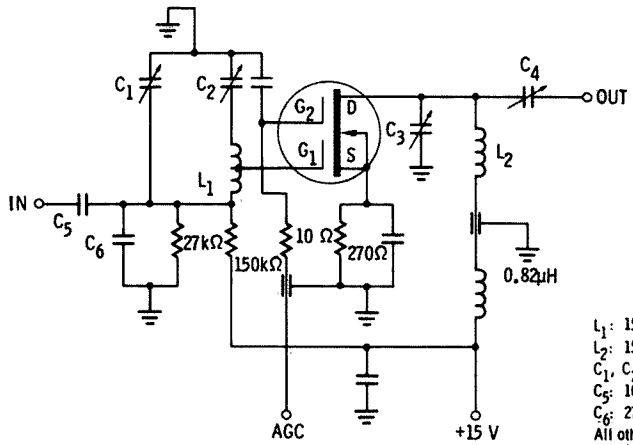
input and output conductances and susceptances of the FT0601 as a function of the agc voltage. This characteristic of the FT0601 makes the device suitable for tuned amplifiers.



- Diode protection of both gates, which eliminates the possibility of device destruction due to buildup of static electricity.

RF Applications

Dual-gate MOSFETs offer two important advantages over bipolar devices in rf applications. First, agc operation is made easier because of the separate signal and agc gates. Secondly, their input admittance does not change with agc; consequently, the performance (center frequency) of MOSFET tuned amplifiers is unaffected. The chief rf applications of the FT0601, listed below, utilize these advantages.

VHF Amplifier. Good-quality receivers use automatic gain control at the front end to improve reception for a wide range of input signal levels. For agc operation, dual-gate MOSFETs have a built-in advantage owing to their separate gates, especially in the VHF region. VHF amplifiers built with the FT0601 eliminate cross-modulation distortion, decrease receiver noise, and avoid shifting of the receiver's center frequency. Figure 4 is a circuit schematic of a VHF amplifier using the FT0601.

VHF Mixer. The FT0601 has good gain throughout the VHF band and can be used as a front-end amplifier. However, the device has a nonlinear transfer function region and, therefore, it can also be used as a VHF mixer to provide conversion gain. The mixing action takes place in the least linear section of the VHF band, and the gain is obtained where the device is completely linear. Therefore, when a VHF mixer is designed, a compromise is needed between gain and mixing action, and, as a rule, gain is sacrificed. The conversion gain is defined as the ratio of i-f power output to rf power input.

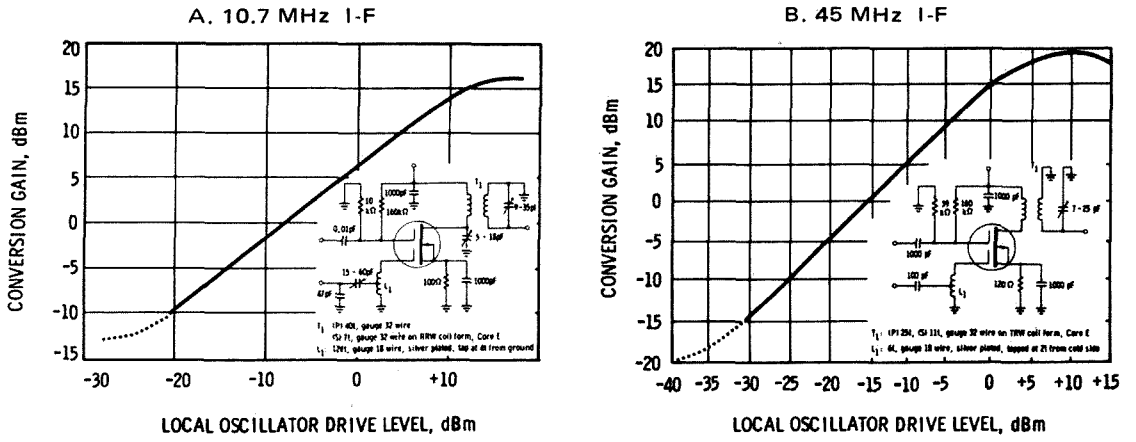

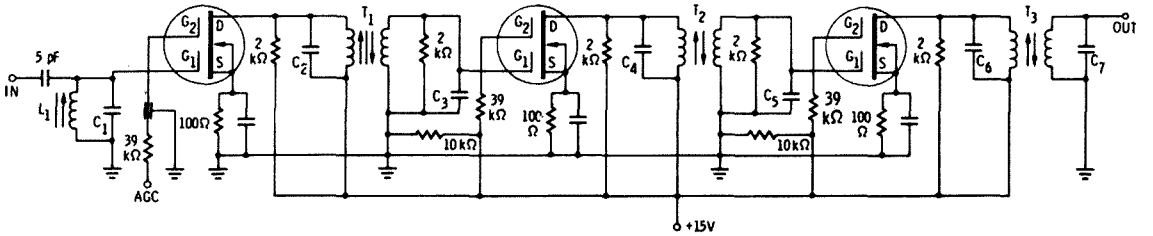

Fig. 5. Conversion gain vs local oscillator drive level for the FT0601.

The amplifier provides optimum rf power gain with the FT0601 when the drain current varies between 8 and 10 mA, while the mixing action takes place at drain currents of 3 to 4 mA. Our experiments indicated that best conversion gain is obtained when the device is biased at 5 to 6 mA of drain current.

local oscillator drive level, and the circuits used to measure the conversion gain are shown in Fig. 5 for 10.7 MHz and 45 MHz. We designed these circuits with emphasis on stability and high gain, thus the chosen bandwidths are not optimum: 1 MHz for the 10.7 MHz signal and about 2 MHz for the 45 MHz signal.

Fig. 6. 45 MHz i-f strip using the FT0601.

When a dual-gate MOSFET is used as a VHF mixer, the local oscillator and rf signals can be applied to separate gates. We obtained the best conversion gain with the rf signal applied to gate 1 and the local oscillator signal to gate 2. We biased gate 1 to dc ground and applied the rf signal to this gate through a conjugately matched network; but did not conjugately match the network to the i-f impedance of the device to avoid the possibility of oscillation. The conversion gain as a function of

IF Strip

Dual-gate MOSFETs are suitable for i-f strips where the Q of the tuning circuit is critical. We built a 45 MHz strip using a FT0601s in all stages. However, to avoid instability, a large amount of mismatch was needed in all stages; therefore, we loaded the stages with 2 kΩ input and output admittances. The circuit schematic of the strip and the performance data are shown in Fig. 6.

Remote Quad Tuning

The cubical quad has become one of the most popular beam antennas for the DX'er. But something less than popular is the problem of tuning the parasitic wire reflector for optimum performance. Many weary miles of tower climbing, seasoned with ripe expletives, have been expended on this labor of love. Field strength meters, arm-waving assistants, neighboring hams, and even CB handsets have been pressed into service. . .after all of which there is lasting doubt that the beast is really adjusted right on the nose. How much happier if this onerous task could be accomplished in the relative comfort of the shack!

Well, pilgrim, your search is over. For tuning a quad can be relegated to the mere twist of a knob as you relax at the operating position.

Whether homebrew or commercial, the length of the quad reflector is commonly cut for one wavelength, identical to the driven element. Tuning is provided by inserting the appropriate amount of inductive reactance – dependent upon spacing from the driven element – to produce the necessary phase shift in the reflector for maximum forward gain or front-to-back ratio.

Figure 1 illustrates three popular methods for adjusting inductive reactance at the reflector. Figure 1A uses an adjustable shorted stub which exhibits an inductive reactance at its open end, the value of which depends upon the position of the shorting bar; 1B incorporates an open stub, the length of which is made greater than ¼ wavelength, so that it similarly exhibits an inductive reactance which can be varied by the capacitor. Figure 1C uses a suitable coil with an adjustable tap, and is the method included with a number of commercially manufactured quads.

As old hands will know, the actual adjustment is quite critical for maximum performance. For example, I have found that with the method of Fig. 1A, plus or minus ¼ in. in positioning the shorting bar

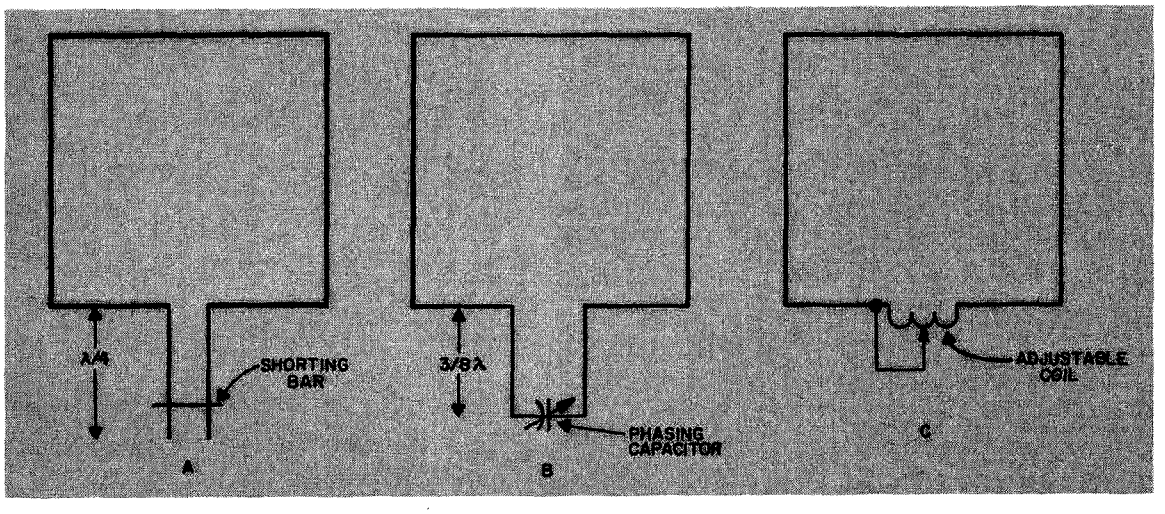

Fig. 1. Basic methods of tuning quad reflectors.

makes the difference between a directional quad and bidirectional stacked dipoles.

The remote method of tuning my quad reflector is an adaptation of Fig. 1B. Since an open-ended stub greater than ¼ wavelength is inductive at its terminals, it follows that extending the length of the stub by any multiple of half wavelengths will produce the same inductive value at the terminals. Connecting a variable capacitor across one end of this extended stub will enable the value of inductive reactance at the other end to be varied.

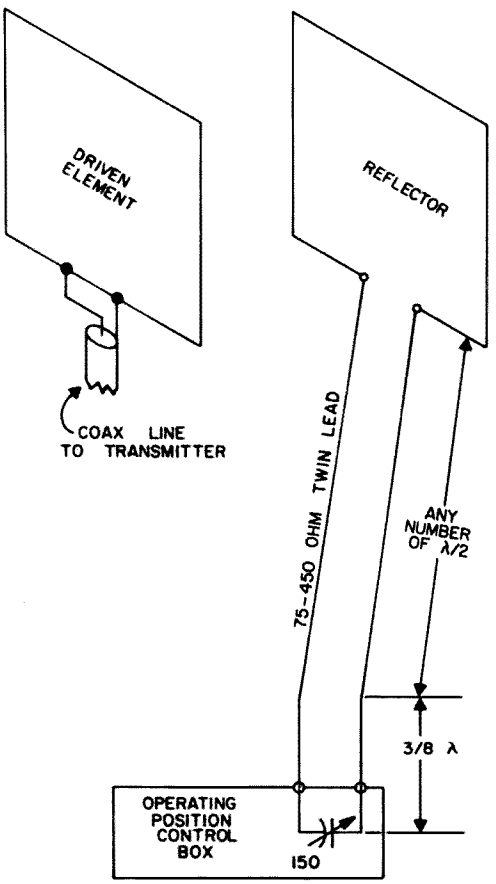

Fig. 2. Arrangement for remote tuned stub.

In plain words, you cut a length of transmission line to the number of half-waves needed to reach from the quad reflector to your operating position, plus an additional 3/8 wavelength. The adjusting capacitor at the operating end may be about 150 pF (variable receiving type). Figure 2 illustrates the setup.

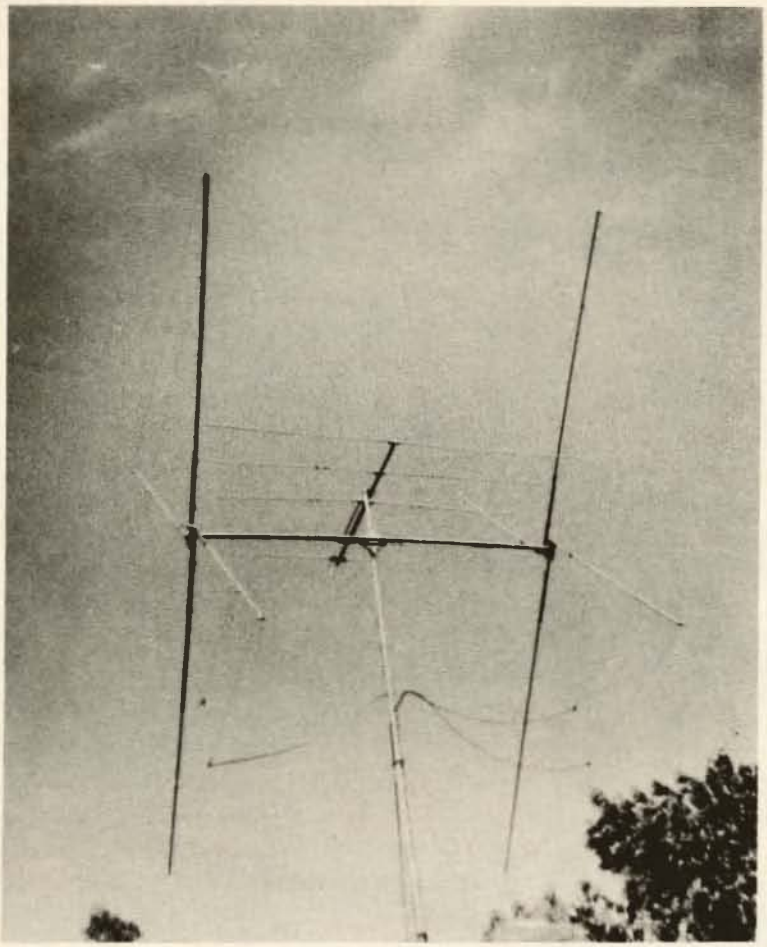
Transmission line used for the elongated stub would ideally be on the open wire, 300–450Ω type. However, if this is physically impractical, 300Ω TV line will work almost as well, though moisture on the line may result in reactance variations out of the adjusting capacitor's range. The best solution was found to be the tubular, foam-filled, low-loss 300Ω TV line, which exhibited minimum variations when exposed to rain or snow.

In calculating overall stub length, the velocity factor of the actual line used must be applied. Taking the basic stub length to the 3/8 wavelength, the formula will be

$$\frac{351}{f(MHz)} \times V \times M$$

where f = resonant frequency of the driven element and V = velocity factor of the type of line used for the stub. Added to the basic stub length must be a length of line suitable to run from antenna to operating position, for which the formula is

$$\frac{468}{f(MHz)} \times V$$



where m = the multiplier to achieve the length required.

For example, using 300Ω TV line with a velocity factor of 0.82 for a resonant frequency of 28.5 MHz, the basic stub length would be 351/28.5 x 0.82 = 10.0 ft. Supposing antenna-to-shack distance is a 50 ft run – an additional length calculated as 468/28.5 x 0.82 x 3 = 40.2 ft. The length of the basic stub, plus the half-wave multiple extension will then total 50.2 ft.

Velocity factors for readily available balanced lines suitable for constructing the elongated stub are as follows:

a) Open wire (any impedance) V = 0.975
b) Flat TV line (300Ω) V = 0.82
c) Tubular TV line (300Ω) V = 0.82
d) Flat TV "twin lead" (75Ω) V = 0.68

Once you have the elongated stub cut to the required length, and connected to the open terminals of the reflector, connect the variable capacitor to the operating end and turn the quad back on to a ground-wave signal; another local ham or a signal generator with short antenna positioned a few wavelengths away. Vary the capacitor and watch the receiver S-meter for a null

10 and 15 meter quad with remote tuning stubs.

on the signal. If none is noted it will be necessary to carefully prune the stub to bring the inductive value into the range of the capacitor. Cut off no more than 2 in. at a time, reconnect the capacitor and try again. Repeat this process until varying the capacitor produces the desired null. Finally prune the stub just enough to bring the null to the mid-value of the capacitor.

It is assumed that the driven element has been resonated and matched to the transmission line before adjusting the reflector stub. Once the stub has been pruned, and power is applied to the antenna through an swr bridge, a distinct variation in swr will be noted as the stub capacitor passes through the null position, and if the driven element is properly matched minimum swr will occur at reflector-optimum setting of the capacitor.

When the quad is facing a ground-wave station it is possible to adjust the stub capacitor for maximum signal, and the setting will be slightly different from that for front-to-back ratio. The capacitor will also compensate for wet weather conditions and permit optimum tuning of the reflector when moving around the band.

For a multiband quad, a separate elongated stub will be required for each reflector. The photo shows my 10 and 15 meter quad (don't be confused by the TV antenna mounted between the elements), with the common transmission line at the left and the two stub lines to the right. While this method has been described for a two element quad, there is no reason why it can't be applied to 3 and 4 element quads, if you care to run the extra lines, or to any parasitic type array for that matter.

With the tuning capacitors mounted in a small box at the operating position, assurance that your quad is giving maximum performance is as simple as just tweaking a knob.

2 Watt 6 Meter Transmitter using the Heterodyne VFO

Bill Hoisington K1CLL
Far Over Farm
Peterborough NH 03458

This article describes the breadboard design, tuneup, and results of an rf power stage on 6 meters using the $2.95 Motorola 3-watt HEP-75 transistor (similar to the famous 2N3866). This rf stage is designed to work from an input power of 120 mW such as furnished by the 6 meter crystal-heterodyne-vfo circuit described in a previous issue of 73 Magazine. Two types of inputs are detailed, one using a single capacitor, and the other a matching network for use with any length of cable. At a dc input power of 2W using a 12V battery, a good clean watt of rf output power is obtained.

Circuit and Design Theory

Figure 1 shows the schematic, using the input matching network. The design of a VHF input circuit can take various forms, depending on whom you read, what you read, and the proposed use of the rig. In

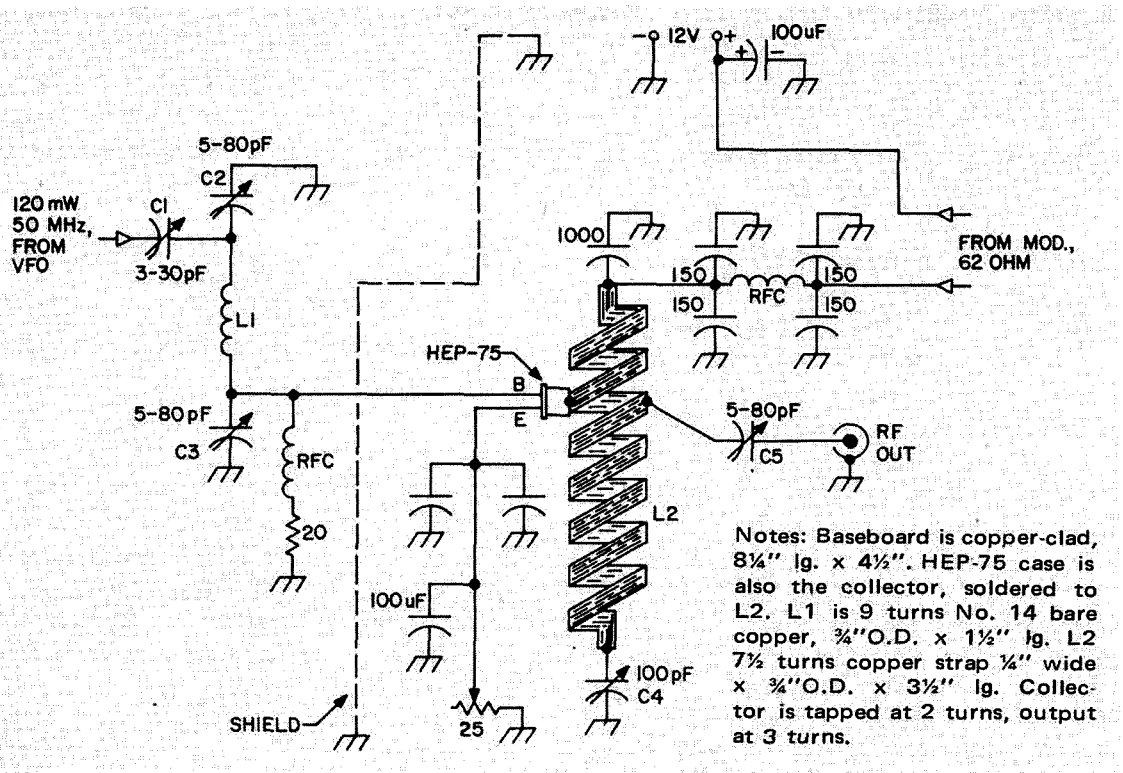

Fig. 1. 2 watt, crystal-heterodyne-VFO 6 meter rig.

this case, we want sure-fire operation, an easy-to-build circuit, freedom from self-oscillation, smooth tuning, 12V operation, and "carrying" type portability for hill-topping emergency use, and mobile work, as well for use at home.

The circuit in Fig. 2 uses a capacitor from J1 to the base. It works, and should be sufficient in the case of an excess of input power (not too likely), and where you don't mind adjusting cable length. However, if you're building up from only 120 mW of vfo output, you may want maximum power transfer along with the ability to match various cable lengths, and direct inputs (as in the case of packaging the entire rig in a box).

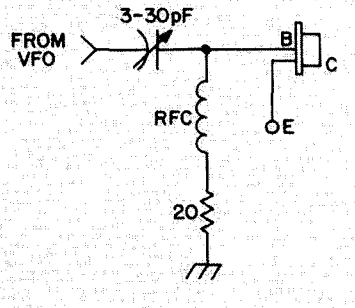

Fig. 2. Simplified input circuit, 2 watt, 6 meters. (Temporary)

The circuit of Fig. 2 is reliable and good for a "quickie" any time. But it does not always furnish maximum drive or best input match unless the cable length and output tap on the vfo output inductor are adjusted. These latter are of course indications of mismatch, but for short lengths of cable there is little loss, so you can operate that way if needed.

DC Base Lockup

This nasty little trouble has not been mentioned in the rather large amount of literature persued here through recent years. I can just hear some know-it-all lads saying, "Ho, Ho, he's just discovered the Poniatowsky effect." Well, maybe so, but whatever its name is, it arrived here and I don't like it! Here's what happens: With an rf choke from the base to ground and *no* resistor, and an rf input driving the collector to about 200 mA, cutting off the rf

excitation does not cut off the collector current. There is no rf involved and it seems to be a dc type of hangup. Just for fun I'll wait until someone tells me its name. In the meantime, back on the breadboard, the cure was easy. Just include a little resistance in the base circuit. That's why the 20Ω job is there.

Input Matching and Base Circuit

After trying out various combinations of circuits as shown by RCA, Motorola, Fairchild, and others, the circuit of Fig. 1 was judged best. Inductor L1 can also be an air-wound coil 5/8 of an inch O.D., 8 turns per inch, with 5½ turns (not too critical).

Just a word of caution here about overloading receiver inputs while testing transmitters. While checking with the lab receiver, with its antenna only 10 in. away from the 1W rf output of the amplifier, the receiver was completely blocked out and detuned by the rf. The addition of only 1 in. of wire as a test antenna brought things back to normal. A very peculiar effect; expect almost anything when you start to run power. In solid-state VHF, "power" refers to anything over 1W.

Emitter Circuit

No trouble here. Two capacitors were used for bypassing, which are not really 100% in parallel. That is, with the ground leads of the capacitors going to slightly different ground points and the two leads cutting down the lead inductance by a large factor, the emitter is pretty well tied down to the ground plane rf-wise. A 25Ω pot controls power output from about 0.25 to 1.0W with 120 mW of rf input power and 2W of dc power.

Due to the base resistor requirements, no limiting resistor was needed in series with the 25Ω emitter pot which operates nicely as an rf power control (although 2W dc input does not particularly strain the HEP-75). A 100 μF capacitor was later shunted from the emitter to ground for better modulation properties.

Collector Circuit

Several requirements must be met here, some of them not usually compatible, but things worked out quite well as you will see in the results section. A good high-Q inductor is desirable for maximum selectivity when loaded by the antenna, and at the same time good heatsinking is needed. Fortunately, there is a design that will accomplish both of these requirements at the same time. The secret; Plenty of copper. Thus the edgewise-wound copper-strap inductor shown in Fig. 1. The collector is internally connected to the case, and to keep the inductance low and the heat conductance high, the case can be soldered directly to the copper strap. Do not use a large iron, and be sure to tin both the strap and the transistor case first. Use the minimum amount of time and heat to do this, consistent with a good solder joint.

Note that the collector is tapped pretty far down on the inductor (near the cold end); this is done for impedance matching purposes. With direct currents of nearly 200 mA at 12V, you can see that the rf impedance will be low. This gets to be a big problem when you get up into the hundreds of watts, but at 2W matching can be done by tapping the collector on the second turn of a 7½-turn coil as shown.

The copper strap also takes care of the heatsink problem by conducting the heat away from the collector in both directions along the strap. With more powerful transistors, use is made of a beryllium oxide or aluminum oxide insulating stud, which conducts heat quite well but *not* electricity. So far they cost a lot more, but we can always hope they will come down in price.

Collector Dip Notes

With the HEP-75 collector circuit detuned, the current is near 200 mA; with it tuned and unloaded, the current drops to about 50 mA just like in the good old days with tubes. Believe it or not, a spark can be seen when applying the pencil test to the high rf end in the unloaded condition. I generally load the circuit with the antenna so that a slight dip of, say, 10% is obtained. With an rf power indicator in the antenna line a precise adjustment can be made.

The RF Output Match

While not critical, the output connection does require care and testing to obtain

a good match and maximum power output at 50 MHz.

Tapped onto L2 and 2½ turns (Fig. 3) is a 5–80 pF Arco compression trimmer (Model 462), which does a good job of matching a 0.9 or 3W bulb to the collector.

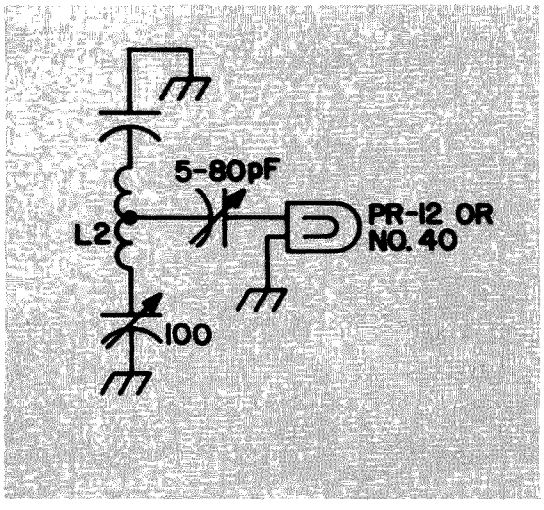

Fig. 3. Output test circuit.

With the input circuit of LI tuned correctly and 180 mA showing in the collector circuit while detuned, and rocking C4 slowly through the dip at resonance, the proper adjustment of output coupling capacitor C5 can be obtained.

The adjustment for a pilot light match is not necessarily the same as for a 50Ω cable. Leading to coax requires readjustment of output capacitor C5 and possibly the tap on L2.

I found 160 mA to be about the maximum output. If you load L2 down to where there is less dip, your power and selectivity against harmonics will suffer. It is best to use a shade less coupling, sacrifice a small percentage of your power, and obtain good discrimination against harmonics. (Don't forget that second harmonic of 50 MHz right in the middle of the FM band!)

Homebrew Wattmeter

This is something I'll really have to look deeper into, because there are rf wattmeters on the market, but they start at $49.50 for 2–30 MHz and go up in price along with the frequency. With all the material that the young builder has to purchase, perhaps on an "allowance" budget, he just has to pass up such luxuries.

In the meantime, back at the old bench, turn to page 259 of Lafayette's 1970 catalog and you will find a list of pilot lights with a wide variety of wattage. You can push these along at a lively dc clip to perhaps twice the rated voltage. After all, most of them sell for only 15¢ to 90¢. The only thing is that after you get up to a watt and over it begins to be a little tough on the eyes! So use a higher rated lamp than actual rf power. In the Lafayette list you will see the number 48 and 49 for 120 mA (good for oscillators), the 40 and 47 at 1W, the PR13 for 2.34W along with the PR12 for 3W, and the 432 and 433 for 4.5W, etc. A lot depends on what you can find in your local hardware store if you're in a hurry right now to know how many watts output you have. There comes to mind the question of whether or not the pilot lamps light to the same brilliancy on rf wattage as they do on dc. All I can say is that when a lamp is lit by rf to the same brilliance, there must be *at least* that much wattage. If the final is tuning nicely at the proper loading point, as mentioned above for maximum power out, it is reasonable to suppose that most of that rf is going into the filament of that pilot lamp, and will show up as heat.

To make a real handy wattmeter for pennies, set up a little panel or minibox with lamp, battery, pot, and dial knob calibrated in watts. To calibrate, simply read the amps times volts for different positions, using the method of successive approximations to get round numbers for easy reading on the dial.

To solder a connection onto the aluminum base of a bulb, use a good clean tinned iron, scrape the aluminum clear of any oxide, and use a rubbing motion of the iron to tin the aluminum for about 3 or 4 seconds. Friction, plus heat and solder flux, helps solder to adhere adequately to aluminum.

For use with the transmitter, just position the wattmeter bulb alongside the one lit by the rf and adjust for the same

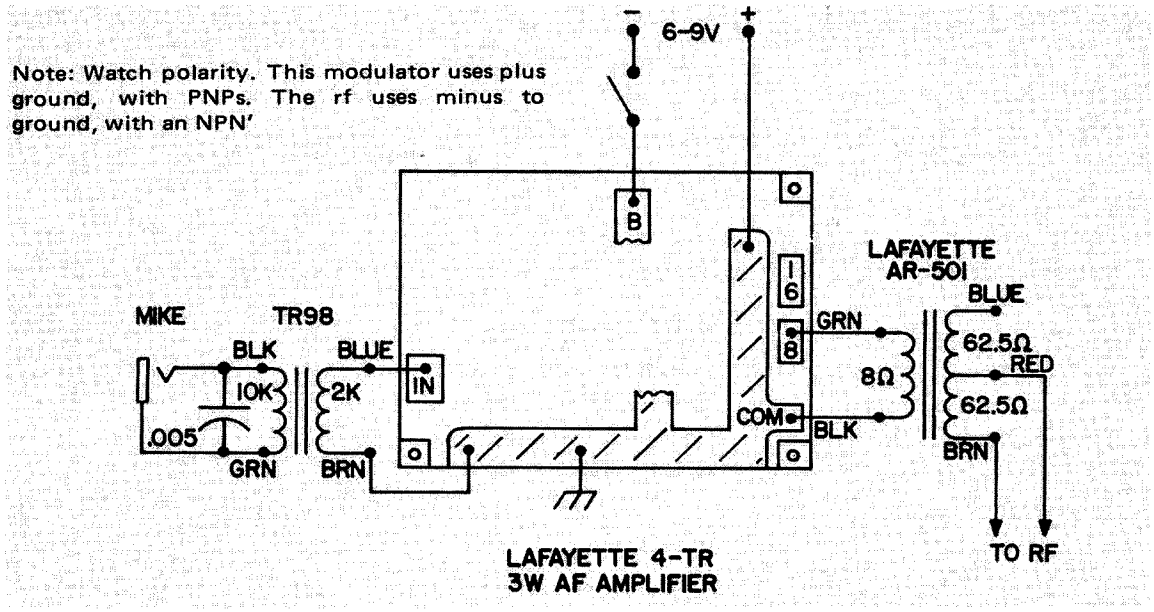

Fig. 4. Modulator circuit, 2 watt, 6 meter rig.

brilliance. The human eye is supposed to be quite good at this type of comparison. It works.

The Modulator

There is a ready-made unit for the modulator, which only costs $7.95 and has 3W of audio output. This is the Lafayette "4-TR," 99E91432. It is a chunky little package, uses an RC-coupled input stage, a transformer coupled driver, and two power transistors in push-pull, with an output transformer having 8 and 16Ω outputs.

The unit fully modulates the 2W rig. At this particular time I have yet to decide between the transformerless output circuits and those using a transformer. It may well be that certain systems need transformers, and others, such as hi-fi sets, are better without them. As some engineers have pointed out (mainly those engineers from telephone companies!), the best of FM broadcasts reach you through a minimum of ten or a dozen transformers, so why worry about one more?

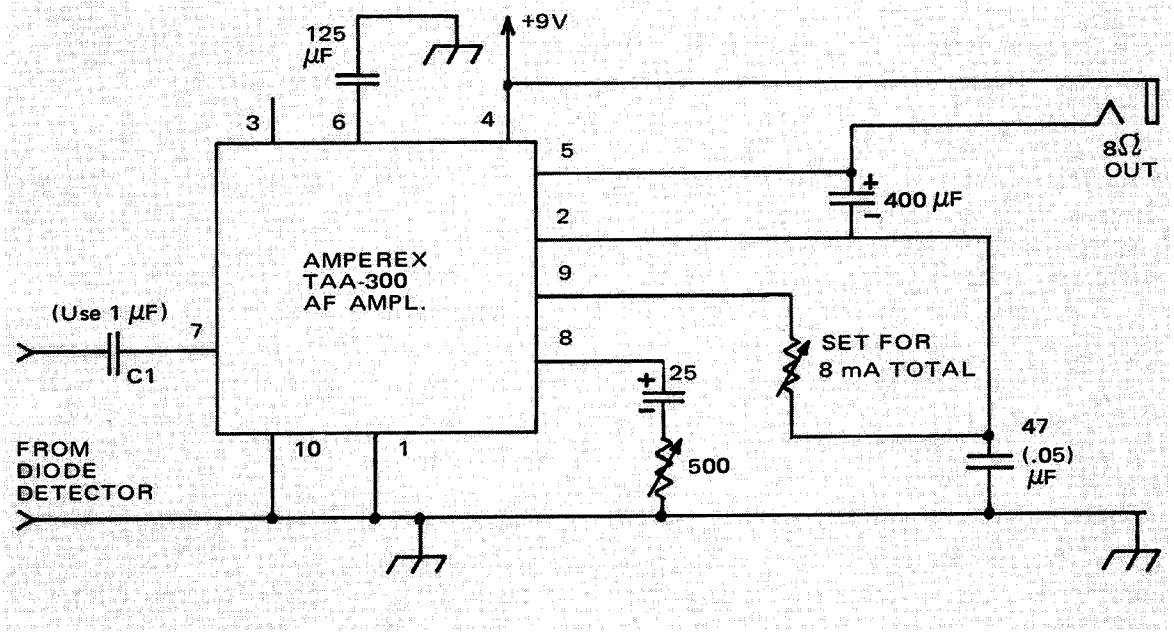

Fig. 5. Modulation monitor, 2 watt, 6 meter transmitter.

So, for a modulation transformer, not having found the ideal as yet, we use another, back to back with the 4-TR winding of 8Ω, The nearest to 75Ω I could find was the Lafayette AR-501, which has an 8Ω winding on one side and a 125Ω winding on the other (centertapped). It worked out fine on the air, in the circuit shown in Fig. 4. As the power goes up on this type of rig, with one or more HEP-75s, possibly to 10W or so, the modulation impedance will drop below the 48Ω region. In this area there is the 10W "universal" transformer with taps at 4, 8, and 16 on one side and 8, 12, 16, 24, and 48 on the other side, at only $3.95. A major benefit of low-impedance solid-state devices now becomes evident, as you don't have to pay for much copper.

In my transmitter, only the final is being modulated. Tests were carried out using only a 6V battery on the modulator because the only 9V batteries I had on hand were those little jobs for Jap radios – and they will *not* furnish 500 mA!

Excellent modulation reports were obtained on the air, however.

A good idea for checking your own modulation on a dummy load before you put it on the air is to use an Amperex TAA-300 integrated circuit, as shown in Fig. 5. This little gem is actually a miniature hi-fi set all by itself, and it really tells you what your own rig – with *your own voice* modulating it – sounds like to others on the band. To do this you need also a set of earphones, with good padding to keep your voice from reaching your ears through the air. The Lafayette Model 8X stereo headphones ($7.95) are excellent for this, with 8Ω impedance per phone. Just connect the two phones in parallel in a three-circuit jack.

Connect a tuned diode receiver in front of the TAA-300 to pick up the rf from the transmitter, and use the Amperex external circuit as shown in Fig. 5.

The TAA-300 is an excellent example of a modern audio-type IC using eleven transistors and five diodes, with a frequency response of 20 Hz to 25 kHz. Naturally, you don't need all that range for voice communications work so the following modifications were used to cut down the highs and reduce the lows. Replace C1, 0.6 μF, with a 0.01, and install a 0.005 across the input jack. Regular treble and bass tone controls can be made up but they should be put in a minibox to minimize hum because there is a lot of gain at 60 Hz in the little tin can. I also put a pot in place of the 48Ω feedback shunt resistor, because making the negative feedback control variable has very interesting possibilities, as you will see when you operate it. The TAA-300 also makes an ideal amplifier for any amateur receiver using transistors.

On The Air

Not waiting to hook up an rf power monitor, I connected the 50Ω cable from my 4-element beam through a ceramic rotary switch for use as in Fig. 6, to change

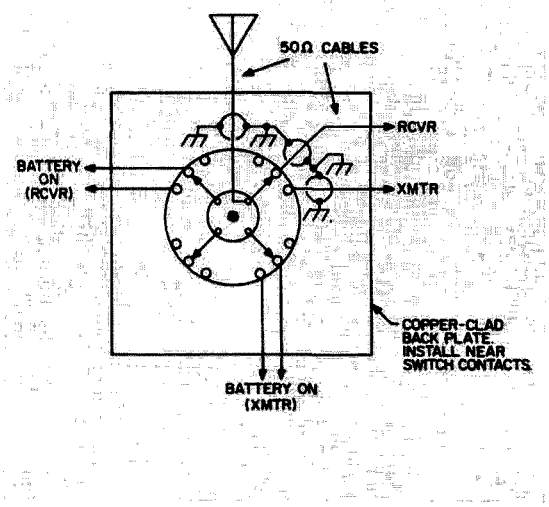

Fig. 6. Send-receive switch, 6 meter, 2 watt transmitter.

over the antenna and turn the receiver and transmitter on and off, and tuned for the same dip in the collector current that had shown maximum power into a PR-12 3W pilot lamp. This did the job. In October 1969, I tuned the vfo to a good loud signal on the band and he came right back to me. This was W1ZLG, a Massachusetts station 55 miles away. His report: "Modulation very very good."

Wichita KS 67212

SEMIAUTOMATIC FM CHANNEL SCANNING

The completion of the second 2 meter FM repeater in Wichita left me with the problem of trying to monitor both repeater frequencies simultaneously, on a one-receiver budget. Manually flipping the channel selector was a tiring method which set me to work on a way to electrically perform this same function with the least expense and design effort. The solution was a circuit made up of a "flasher" module, two transistors, and five resistors.

I call this a "semiautomatic" scanner because the unit will not "lock on" when a signal appears on a vacant channel. It

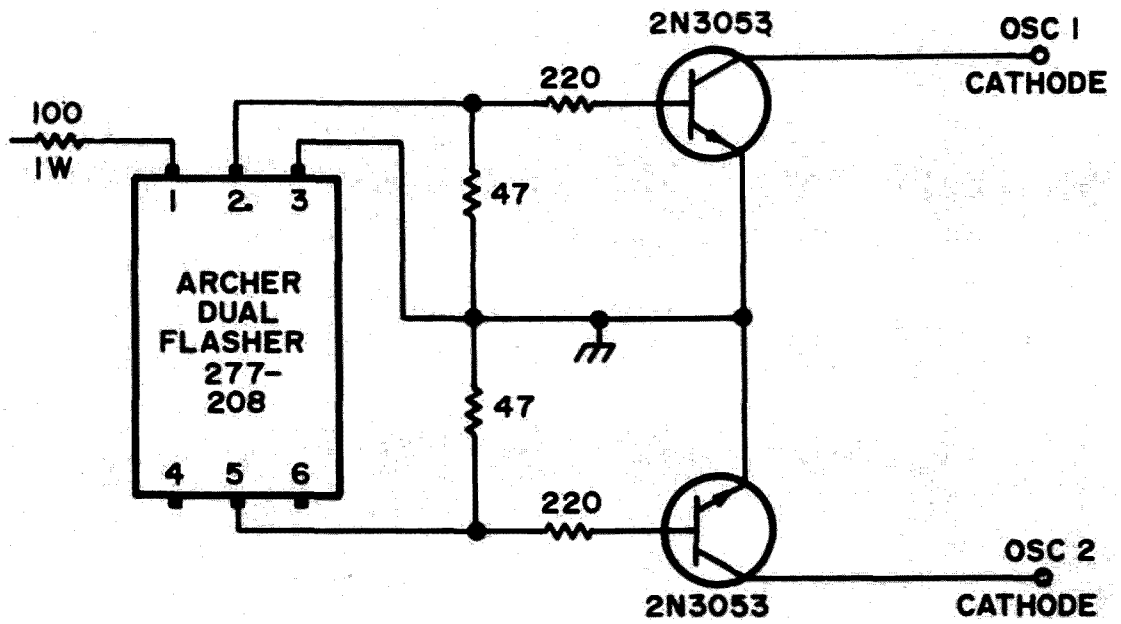

Fig. 1. A nonlocking scanner can be made easily by using an Archer dual flasher in conjunction with an external switching circuit.

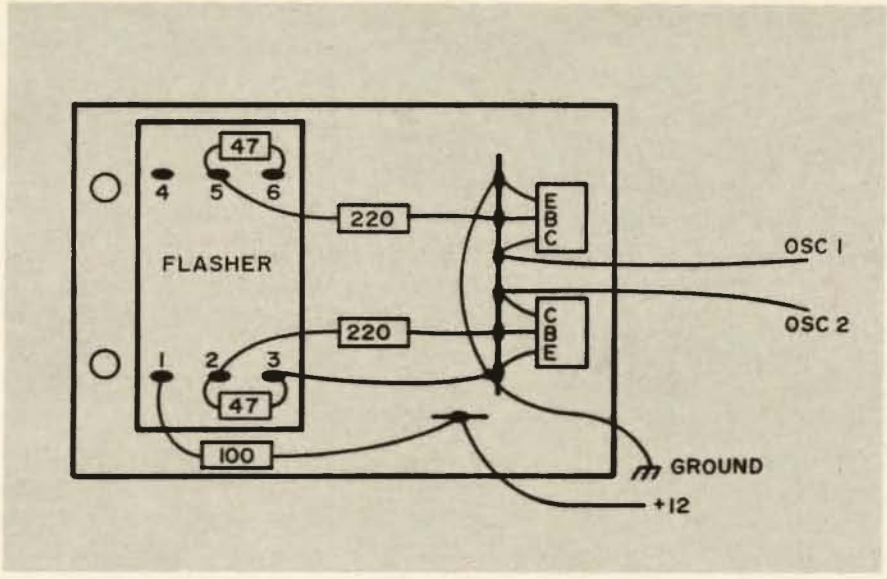

Fig. 2. Parts arrangement for mounting in GE Progress Line unit. When the scanner is in operation, all other cathode grounding circuits must be out of the circuit.

simply scans by monitoring first the F1 channel, then F2. When the operator wants to halt the scanning action, he merely turns off the unit by placing the frequency selector switch on the rig to the appropriate channel.

My mobile rig is a GE Progress Line, which switches receive frequencies by dc grounding the cathode of the desired oscillator. The idea was to use transistors to switch the oscillators, then make one of the low-priced experimenter flasher modules turn the two transistors alternately on and off. The module selected was the Radio Shack *Archer* dual flasher (277-208). The *Archer* unit is a 6V transistor multivibrator which cost $2.50. It can be easily duplicated, but the low-priced

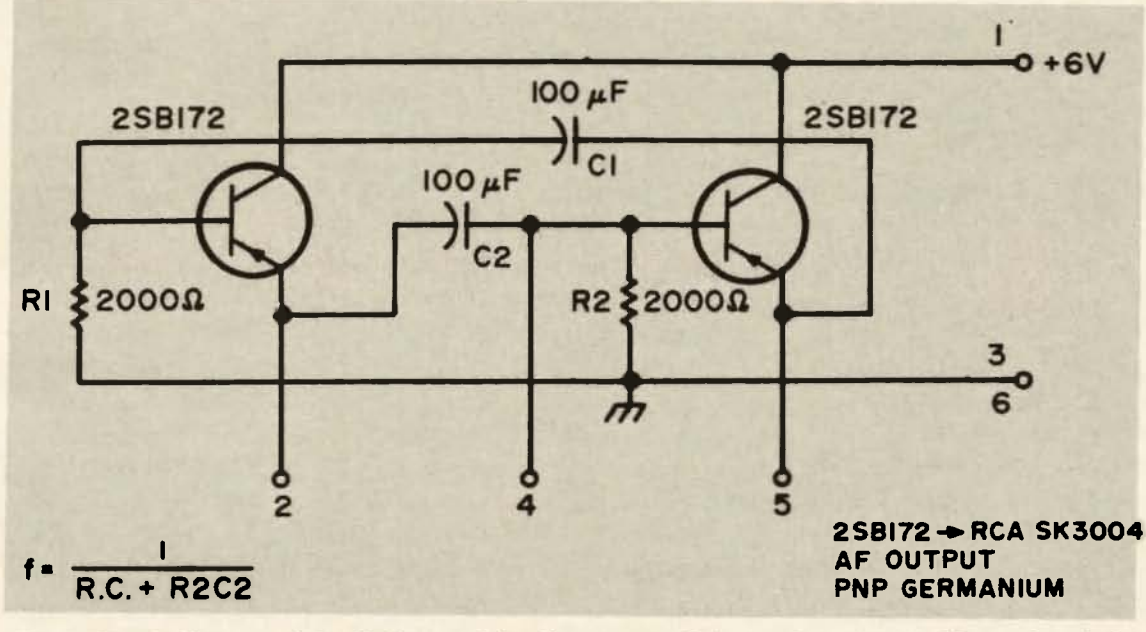

Fig. 3. Circuit diagram of the flasher module. Changing the RC values here (text) will permit variation of the switching frequency.

module is in an attractive case and includes a mounting socket.

For cathode switching, I used 2N3053 transistors because they were on hand; they are also very inexpensive if purchased new. If you make any substitution, choose a transistor that has a high collector–emitter voltage rating to withstand the potential difference between the floating cathode and ground.

In the circuit (Fig. 1) the 100Ω resistor is used to drop the 12V battery voltage to the level required by the module. The 47Ω half-watts are the load resistors, and the 220Ω resistors are used to supply a proper keying voltage to the transistor.

The "channel scanner" can be mounted up front with the control head or in the trunk with the receiver, as mine is (Fig. 2). When the unit is in operation, all other channel grounding must be lifted. On my rig I have a three-position switch which selects .94, .82, or, in the third position, leaves the cathodes floating and applies voltage to the scanner. The scanner can be permanently wired into the receiver. The switching transistors, with no voltage applied, offer a very high resistance which does not affect normal operation. If you have to rewire your receiver for remote switching, be sure to provide an rf ground at the tube cathode. GE uses a .02 μF capacitor.

The *Archer* flasher module is designed to operate at a frequency of 2.5 Hz. In this way, each channel is sampled about twice a second. The frequency can be changed by prying open the flasher module and changing the RC values. The circuit works according to this formula: I found that a frequency of 0.25 Hz was best for me (R1 and R2 20K, C1 and C2 unchanged). At this rate each channel is sampled for two seconds. You can also "lopside" the rate. I sample 146.94 for two seconds and 146.82 for 0.2 second (R1 = 2K, R2 = 20K, C1 and C2 unchanged).

I have been using the scanner for three months with no problems. The unit may not be as convenient as two receivers, but for the price, the "channel scanner" is a good way to always know what is going on, and where.

... WAØQPM ■

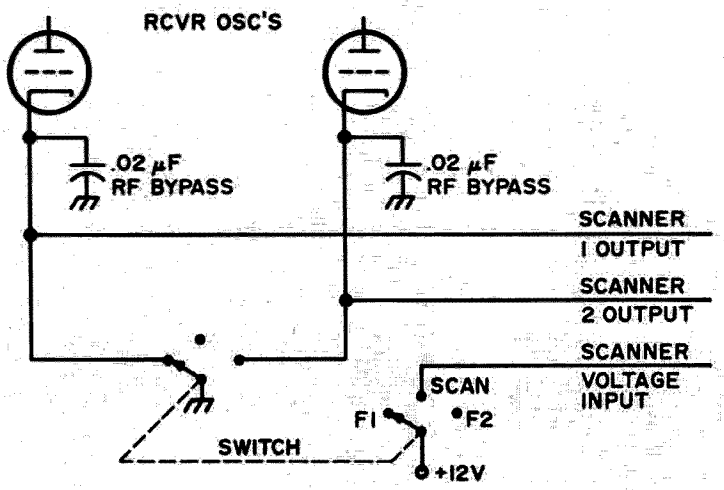

Fig. 4. This wiring diagram shows how the frequency selection is controlled. In the F1 and F2 positions, the appropriate cathode is grounded directly. In the scan position, the cathode ground is lifted and +12V is applied to the scanner.

LOW COST AUTOMATIC KEYER: A "FIRST PROJECT"

If you don't build, START... if you do, try this one tonight

Here are details for constructing a 3 x 5 in. solid-state automatic keyer containing as few as two dozen components and five transistors. The speed range is from 10 wpm to far too fast for me. Over the past two years several versions of this keyer have been built and I have found the circuit to be very tolerant of transistor substitution (get 'em out of the junkbox, computer boards, or old transistor radios). The current drain is low (8–15 mA) and the unit performs well for a minimum-cost project.

Application

If you already own a transceiver with a built-in sidetone oscillator and have 12V ac available, you need only build the basic circuit Fig. 1, omitting the area in dotted lines. The circuit may be tucked inside your transceiver or mounted in a standard 3 x 5 in. minibox. If installed internally any convenient front panel control may be changed to one having the additional 100 kΩ speed control section needed without the necessity of hole drilling. A clear plastic disk may be installed behind the existing knob for speed adjustment, thereby maintaining the original appearance of the rig. On units with the earphone jack on the front panel, you may consider moving this jack to the rear apron and installing the speed control in this location.

Construction

Virtually all the components are point-to-point wired; therefore, if you enjoy making circuit board projects, a full-size layout is included in Fig.2. Figure 3 is a large component placement diagram. Several manufacturers produce copper foil tape, and a board may be made without etching by merely attaching pieces of this foil tape to heavy acetate or other base material. When using this method, it is imperative that a low-wattage soldering

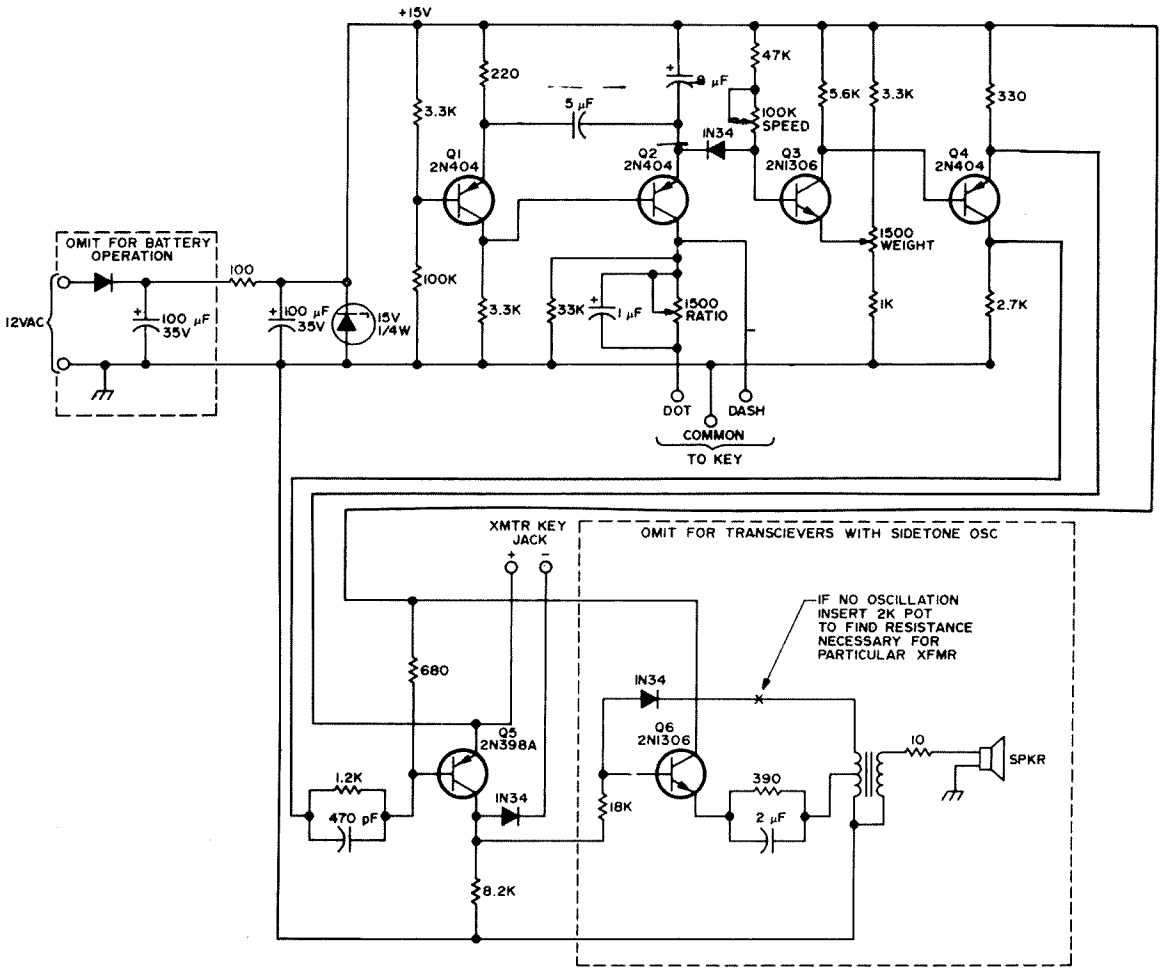

Fig. 1. Schematic diagram for the keyer. Note the marked-off areas at the left and right of the basic circuit. The enclosed area at the left is a rectifier so the power can be drawn from an existing 12V source. The sidetone oscillator is shown at right.

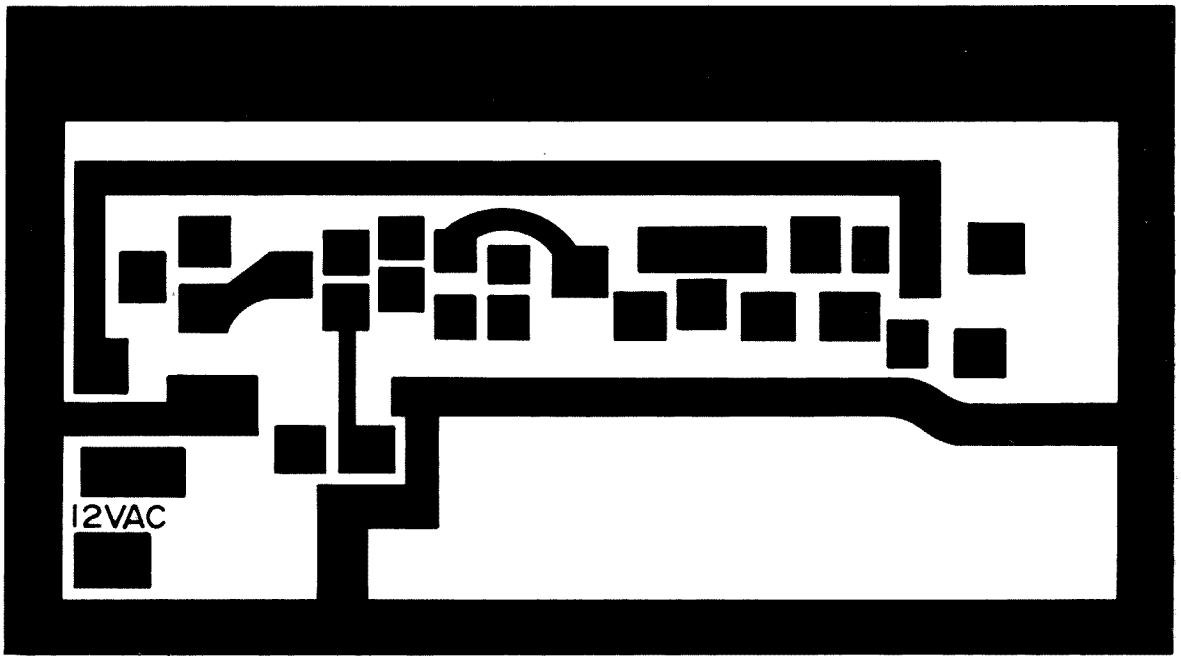

Fig. 2. This drawing may be used as-is to photographically produce an etched circuit board for the keyer assembly.

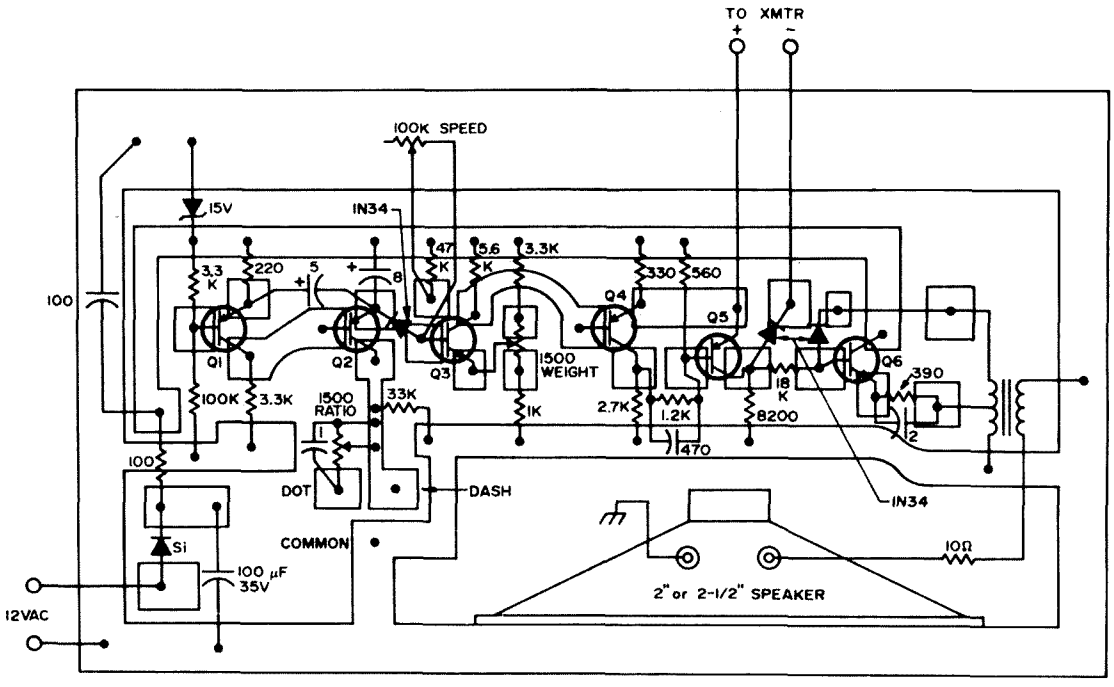

Fig. 3. This composite sketch should help in positioning of parts on the etched board.

iron be used to protect both the tape and the semiconductors during assembly.

A third approach is to use Vector board or Plexiglas and drill holes using the layout in Fig. 1, which will accept the Teflon base pin standoffs which are so common in many types of surplus gear and computer boards. Using this method, only three or four jumpers are required for the entire project. Should you elect to use the printed board or tape, solder all components to the foil side of the board. This will allow you to drop the completed board inside the minibox or secure it inside your rig without the need for electrical spacers or other insulation. This approach also saves you about 50 holes which you may need for a later project.

The speaker and transformer came from an old transistor radio. The last keyer I built used a driver transformer in the output, and even with the terrible impedance mismatch there was ample volume. Transistor Q6 can be almost any NPN audio transistor. Transistors Q1, Q2, and Q4 are very common on surplus boards or are available from Poly-Paks for about a dime apiece. Transistor Q3 is not critical and most NPN types work well. The transistor used for Q5 must have a V_{ce} rating in excess of the voltage at the transmitter during key-up periods. A 2N398A has a V_{ce} and V_{bc} rating of 105V, which is adequate for most transmitters. I found this transistor in a surplus pilot lamp assembly (24¢). The 1N34, zeners, and power supply diodes are all off computer boards, and with the exception of the zener, which should be 14–18V, other diodes may be substituted.

Circuit Description

This circuit, though relatively simple, produces dots and dashes which are self-completing. An audio oscillator provides ample volume for group work (if incorporated). This unit was designed for transmitters which are grid-block keyed. Cathode keying may be accomplished by replacing the 8.2 kΩ Q5 collector resistor with a reed relay or other sensitive relay.

Transistors Q1 and Q2 produce a sawtooth pulse for timing. The particular transistors used as well as the applied voltage will affect the speed range. If you

desire to alter this range, increase the value of the 5 and 8 μF capacitors for slower speeds and decrease these values for faster speeds. Transistor Q3 acts as an amplifier, while Q4 and Q5 form a trigger circuit to key both the transmitter and the audio oscillator.

Power Source

A simple but effective power supply can be obtained by connecting a few components across the 6V filament line, as shown in Fig. 4. Since the current drain is

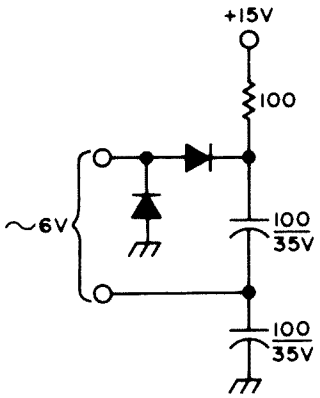

Fig. 4. A simple filtered voltage doubler circuit will convert the 6V ac filament line to 15V dc.

so small, though, a simple battery – connected between the 100Ω resistor and ground – will last a long time. You might even hunt around inside your rig for a 16V cathode resistor point and tap the necessary power there.

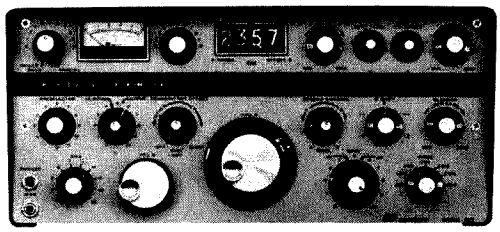
MANUFACTURERS



SPEC SHEETS – INSTRUCTION BOOKS

While our typesetting and art departments are not exactly underburdened, they are not all that flat out either. Neither is our printing department, so if you need any spec sheets made up or instruction booklets for your equipment, why not get in touch with us for a quote. We have the technical department to write it, edit it, set it in type, take pictures of the equipment, lay out the booklet or spec sheet, paste it up, and print it. After all, we turn out two rather good sized magazines a month plus a lot of brochures, letters, promotions, and even a fair amount of job work for our locality.

Perhaps you need counter cards, posters, bumper stickers, or almost anything else that is printed or silk-screened?

Feature This

Signal/One's CX7 gives you

More performance than any transmitter/receiver combination

More convenience than any transceiver

More versatility

Compare the CX7 with any receiver for sensitivity, selectivity options, dynamic range, AGC merit, VFO smoothness, interference rejection.

Compare the CX7 with any transmitter for continuous power output in all modes, P.A. ruggedness, crisp audio punch, low distortion, instant CW break-in and spotting, quick band-change.

Compare the CX7 with any transceiver for total size and weight.

Consider the best at an amateur retail price of $2195.

Write for all the details of the magnificent CX7 from Signal/One, Box 11STO.

AC SWITCHING WITH SELF-POWERED ICs

A new approach to power switching of ac circuits: RFI is eliminated, power supply diodes are protected, switch contact wear is reduced, and tube heater life is extended!

A cure-all to ac switching problems? Not so! But RCA's little CA3059 integrated circuit device goes a long way in eliminating many of the bugs we inherited with Tesla's genius. Formerly known as a monolithic silicon zero-voltage switch, it is now more handily identified by RCA's "CA" number. It is no bigger than a 2W resistor, yet it contains its own power supply and all the other functions shown in Fig. 1. When used with a half-dozen or so other common components, it does many wondrous things. Several are described in this article.

Basically, we would like to accomplish switching when there is no incoming voltage; that is, when the power line voltage crosses zero. This happens twice each cycle, or 120 times per second at 60 Hz. If we switch at this precise moment, no current is flowing through the switch; thus, radio-frequency interference is eliminated, as is contact wear. Incandescent devices, such as tube heaters and pilot lights, which have very low cold-resistance, are heated up "gradually" during a half-cycle if voltage is applied at one of the "zero" crossing times. They are, therefore, not subjected to a destructive high-current surge as before. In the same manner, we reduce the high surge current and minimize the peak inverse voltage imposed on our rectifiers when initially turning on a power supply. The zero-crossing detector in the CA3059 synchronizes the output pulses of its circuit with the time of zero-voltage in the ac cycle. Figure 2 shows this relationship.

But to be useful in switching normal loads, an external power device is needed. Thyristors such as SCRs (half-wave) or triacs (full-wave) are ideal for this purpose. Either one is readily triggered by the 100 μs pulses from the CA3059. The zero-voltage switch is designed primarily to trigger a thyristor that switches a resistive load.

Because the output pulse supplied by the CA3059 is of short duration, the latching current of the thyristor becomes a significant factor in determining whether other types of loads can be switched. (The latching-current value determines whether the thyristor will remain in conduction after the trigger pulse is removed.) Provisions are included in the CA3059 to also accommodate inductive loads.

For example, for load currents that are less than approximately 4A rms (or that are slightly inductive), it is possible to retard the output pulse with respect to the zero-voltage crossing by insertion of capacitor C_x from terminal 5 to terminal 7 as shown in Fig. 1. The insertion of capacitor C_x permits switching of loads that have a slight inductive component and

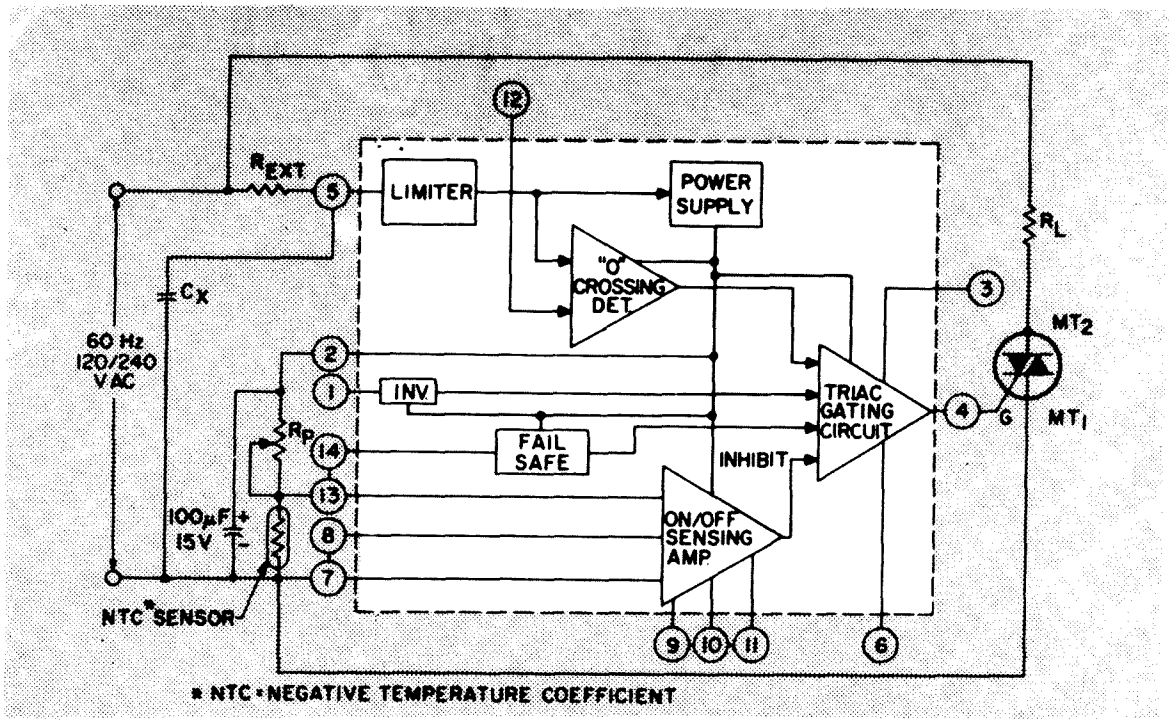

Fig. 1. Functional block diagram of CA3059. Few external components are required in this basic circuit when used to trigger the gate of a triac. The sensor may be a temperature-sensitive thermistor, a photoelectric cell, or a simple off-on switch.

that are greater power than approximately 200W. For loads less than 200W, it is recommended that the user employ the RCA-40526 sensitive-gate triac with the CA3059 because of the low latching-current requirement of this triac.

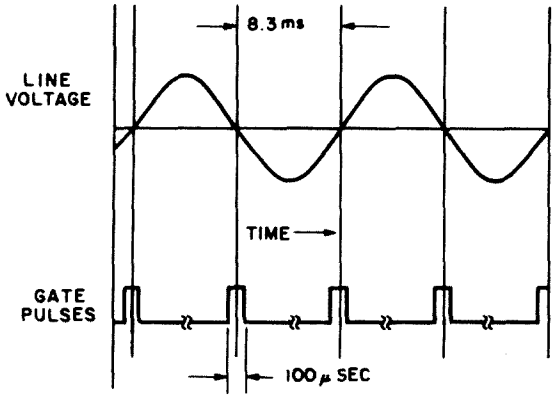

Fig. 2. Timing relationship between output pulses and the ac line voltage. Notice that the gate pulses are present to trigger the triac at zero line voltage.

Figure 3 shows an application which is useful in switching noninductive loads. Lamps and electric heaters can be controlled in this circuit by a simple switch, photoelectric cell, or temperature-sensing thermistor.

Inductive loads up to 200W can be controlled by the configuration shown in Fig. 4. In this case, terminal 12 is connected to terminal 7, and the zero-crossing detector is inhibited. Whether a "high" or "low" voltage is produced at terminal 4 is then dependent only upon the state of the differential comparator within the CA3059 integrated circuit, and not upon the zero crossing of the incoming line voltage. Of course, in this mode of operation, the CA3059 no longer operates as a zero-voltage switch. However, for many applications that involve the switching of low-current inductive loads, the amount of RFI generated can frequently be tolerated. This curcuitry is particularly useful as a differential comparator. Such comparators have found widespread use as limit detectors which compare two analog input signals and provide a go/no-go output, depending upon the relative magnitudes of these signals. In many industrial control applications, a high-resolution, fast switching unit is not essential. The CA3059 is ideally suited for use in such applications.

The chart below compares some of the operating characteristics of the CA3059, when used as a comparator, with a typical high-performance commercially available IC differential comparator.

PARAMETERS	CA3059	Typical IC Comparator
1. Sensitivity	50 mV	2 mV
2. Switching speed	>20 μs	90 ns
3. Output drive capability	4.5V at ⩽4 mA	3.2V at ⩽5 mA

The CA3059 can be used as a simple solid-state switching device that permits ac currents to be turned on or off with a minimum of electrical transients and circuit noise.

The circuit shown in Fig. 5 is connected so that after switch S1 is closed, electronic logic waits until the power-line voltage reaches zero before power is applied to the load. Conversely, when the switch is opened, the load current continues until it reaches zero.

This circuit can thus switch a load at zero current regardless of whether it is resistive or inductive. The maximum load current that can be switched depends on the rating of the second triac. If it is an RCA-2N5444, an rms current of 40A can be switched.

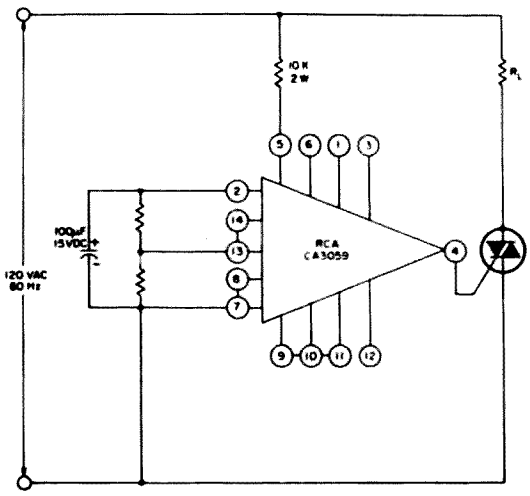

Fig. 3. Controller for resistive loads. The RCA 2N5444 triac can be used for load currents up to 40A. The RCA 40668 triac will switch intermediate loads and the 40526 will handle lighter loads and those which are somewhat inductive.

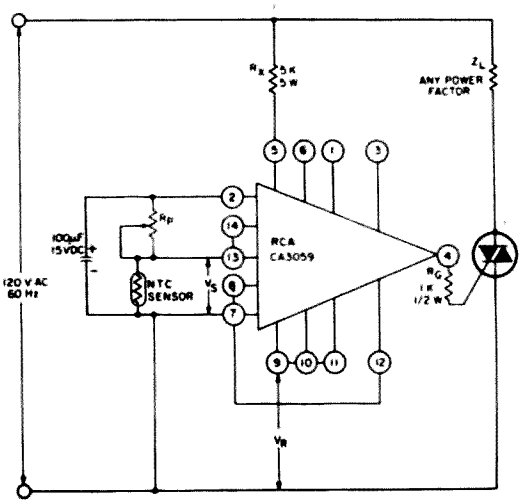

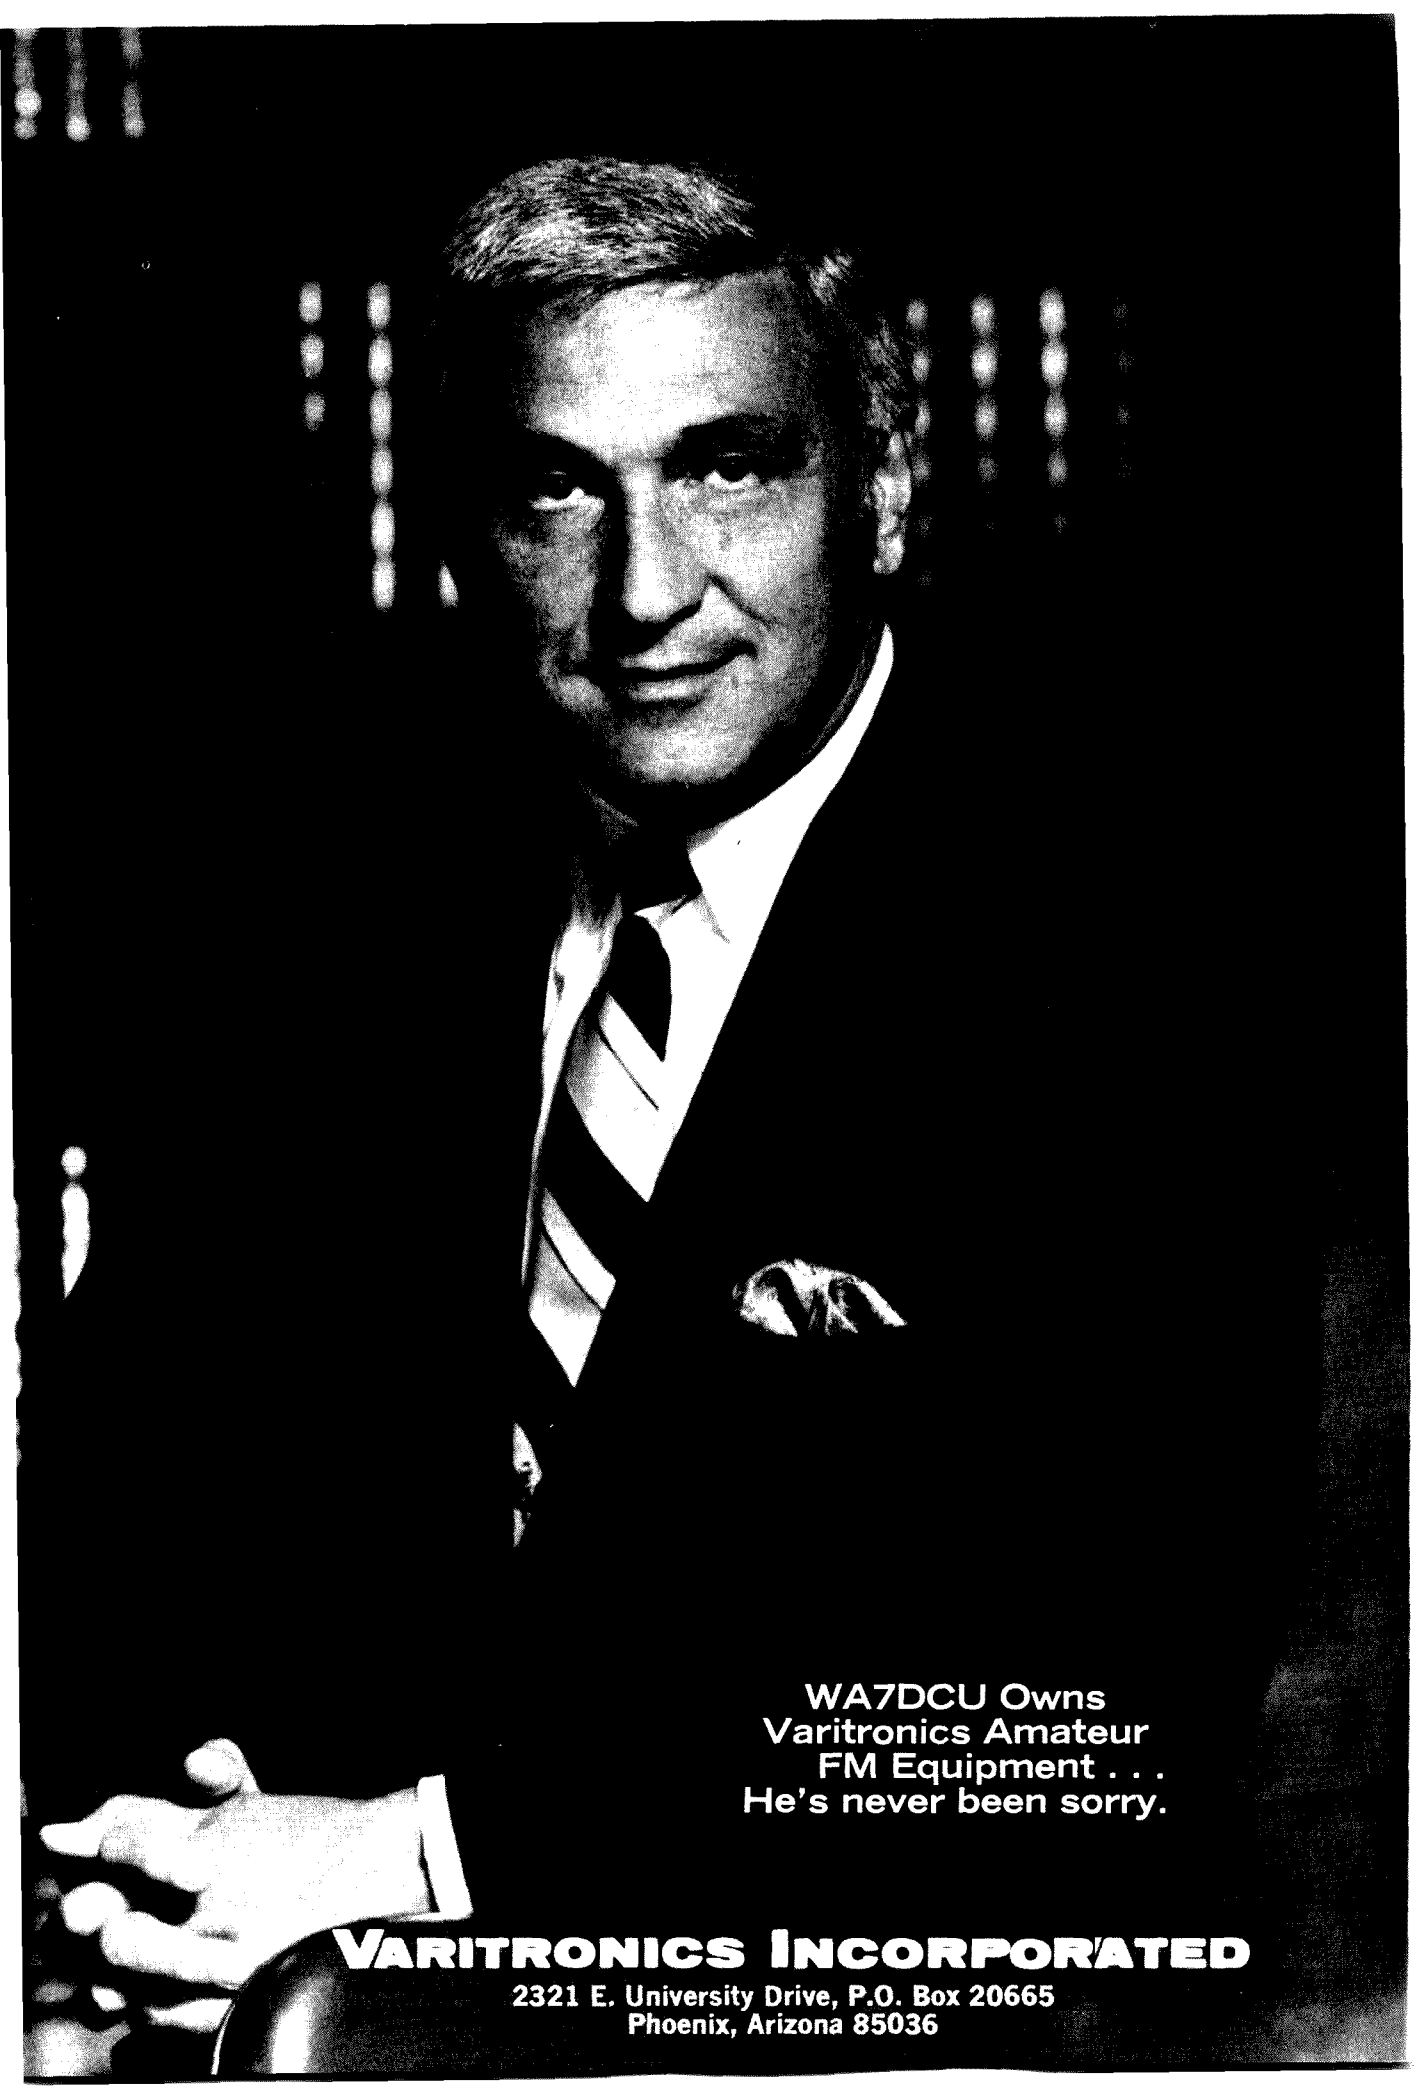

Fig. 4. Differential comparator circuit. The load is switched on when the voltage difference between V_S and V_R becomes less than 50 μV. Note the jumper between terminals 7 and 12, which deactivates the anti-RFI feature.

Figure 6 is a schematic diagram of the CA3059 zero-voltage switch. This should prove helpful to the more advanced experimenter who wishes to design his own circuits for specific applications. Some of these may include:

- Relay control
- Heater control
- Valve control
- Lamp control
- Photosensitive control
- Synchronous switching of flashing lights
- Power one-shot control
- On-off motor switching
- Differential comparator

By referring to the schematic and to the functional block diagram of Fig. 1, we can identify the following circuits within the zero-voltage switch:

1. Limiter, power supply – permits operation directly from an ac line.
2. Differential on/off sensing amplifier – tests the condition of external sensors or command signals. Hysteresis or proportional-control capability may easily be implemented in this section.
3. Zero-crossing detector – synchronizes the output pulses of the circuit with the time of zero-voltage in the ac cycle to eliminate RFI when used with resistive loads.
4. Triac gating circuit – provides high-current pulses to the gate of the power controlling thyristor.

Phoenix, Arizona 85036

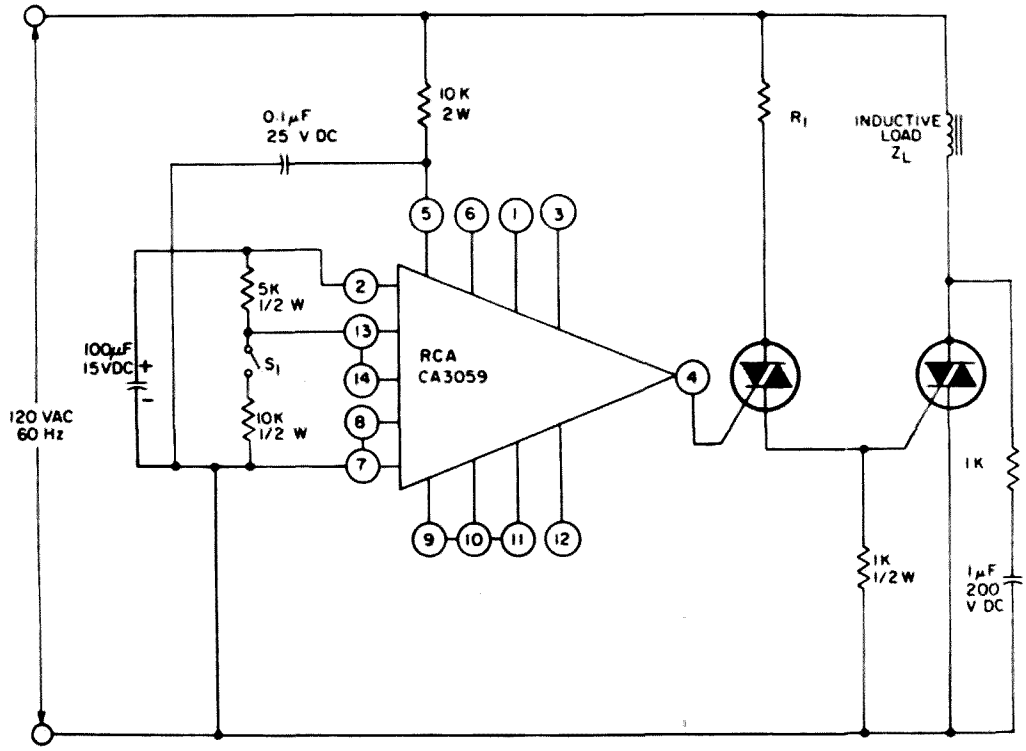

Fig. 5. Practical power switch. Heavy inductive loads can be handled by adding the 0.1 μF capacitor and by cascading the two triacs (RCA 40526 and2N5444). With the latter heavy-duty triac, R1 should be the highest suitable value less than 10 kΩ.

In addition, the CA3059 also provides a built-in protection circuit which may be connected to remove drive from the triac if the sensor opens or shorts. And thyristor firing may be inhibited through the action of an internal diode gate connected to terminal 1. In addition, high-power dc comparator operation is provided by overriding the action of the zero-crossing detector.

Additional information is available in RCA specification sheet File 397 and companion application note ICAN-4158.

51J AND R390 SERIES COMMUNICATIONS RECEIVER

At a time when Communications equipment has become more sophisticated, more reliable and more condensed in size; the trade has been offered less and less in variety and quality than ever before. So as to reverse this trend we offer the 51J and 390 series receivers. Although created in the 50's for military surveillance work these superb sets have been overhauled and modernized and generally speaking are the very best short wave communications radios available. To those of you discerning readers who, tired of mediocrity, want the last word — consider the purchase of a 390 or 51J.

The 390 or 390A or 391 offers digital readout to any discrete frequency within the range of 540 KHz thru 32 MHz to an accuracy of 300 Hz. You can tune to WWV or CHU while the set is off and cold — then turn on the set — turn up the volume and have your station perfectly tuned in. Of maximum sensitivity, the 390 series offers six steps of selectivity from a gate of 100Hz thru 16KHz. Moreover, if used for Moonbounce or sophisticated converter work there is also an audio filter to further narrow the bandpass to as little as 10Hz. Two audio channels, a Geneva drive and a remarkable avc bus are also features of these fine sets.

We have installed compatible sideband detector in these sets and have thoroughly rebuilt each module such that we can warrant each set for a full 180 days from your receipt. Having tried the rest why not have the best — contact us today for a delivery schedule to meet your needs. Prices are FOB Harvard but include Operating and Instruction Book and special shipping container.

Prices for 51J series from $600 to $1033.
Prices for 390 series from $1133 to $2033.
Call us today for more information.

E. E. Krebsbach pictured in recent years at the KGCX mike

The scene is eastern Montana, circa 1926. Seated before a roll top desk on which is stacked a small but complete broadcasting station and engaged in winding a hand-cranked phonograph is E.E. Krebsbach, entrepreneur of Radio Station KGCX, then located in Vida, Montana. The phonograph was vital to the operation of the station, its broadcast music being produced by the simple expedient of placing its microphone (which formerly saw service as a desk-stand telephone) in front of the Victrola.

Vida, a hamlet with a population then and now of only about fifty people was, in 1926, not blessed with electric power lines so the seven and one-half watt signal of KGCX was generated with the aid of a thirty-two volt farm light plant.

Farmers of the area, their day's work done, would fire up their crystal sets or perhaps a squawky Grebe regenerative receiver to listen to the evening's program on "that banker feller's station over in Vida." Reception was mostly via headphones except for those rare occasions when (wonder of wonders) relatively distant CKCK located in Regina, Saskatchewan, achieved loudspeaker levels with their signals. Such an event caused businessmen in the towns of the area to hurry home to bring their wives and children "down town" to hear this marvel of the Twentieth Century. The trip to Main Street was made at breakneck speeds in Model T Fords with much dust generated from the unpaved streets, lest the signal fade out before the entire family heard it (invariably their comment was "It was coming in RIGHT ON THE LOUD SPEAKER") and because in those days, there usually was only one receiver in each village, more often than not being owned by the town physician or druggist, as befitting persons representing Science in the community.

The operator of the radio receiver sat amidst a farrago of wires, dry batteries, wet

batteries, gooseneck speaker, huge loop antenna, etc., and was regarded with considerable respect in the community for his ability to snatch music and voices out of the air. The reader should understand that just anyone could not, of course, and would not be permitted to operate the radio receiver. One had to be qualified as a RADIO EXPERT. Many dials and knobs had to be manipulated precisely to bring something intelligible out of the squawks, squeals, and static crashes produced by the receiver, and if the expert was out of town, the radio was mute until he returned. The townspeople stood around it when it was operating, listening on multiple pairs of headphones all plugged into the same jack.

Telephones of the hand-cranked variety were commonplace in the villages of the area by the mid-Twenties, and the Montana mind could comprehend how talking across miles of wire was accomplished. The process of radio broadcasting, however, was not so easily understood. It was something tinged with wonder, with sheer magic, with unbelievability that a man could speak into a microphone and *be heard miles away without benefit of any connecting wires between the two points.* A radio tuned to Krebsbach's station was set up on a kitchen table (the humble origin of the table was disguised by a generous use of bunting draped around it) at a school carnival in the area. One Scandinavian farmer, upon being informed that the music emanating from the radio was coming through the air from Vida, declared emphatically that "SUCH A TING YUST CAN'T BE DONE" and explained the whole phenomenon away as being accomplished with the use of a phonograph concealed under the table's bunting.

Early operation of the station was extremely informal, and the financial rewards small. Krebsbach once accepted a rooster as fee for advertising a sale of roosters. In the absence of telephones, farmers often used it to communicate with their homes.

Picture in your mind's eye, if you will, a distinguished silver-haired United States Senator with a white-vested expanse of abdomen of senatorial proportions, clutching the telephone mike in a well-manicured paw, and in all seriousness, campaigning for re-election over KGCX. Some weeks later, his challenger also spoke over the station, but the strength of the signal on that occasion was weak, due to a loose screw in the station's antenna system (which was all of forty feet high) and unjustified complaints of bias on the part of station management were heard.

Vida was by far, the smallest town in the U.S. that had a standard broadcast station. Radio maps of the United States issued by RCA about 1927 show a vast expanse of Western territory devoid of dots representing broadcast stations except for the one designating KGCX.

In addition to lacking electric power lines, indoor plumbing (to this day, it is still equipped with what the flowery French call *"chalets de necessite"*), and a number of other metropolitan conveniences, Vida also suffered from a lack of public transportation, inasmuch as it wasn't served by any railroad or bus line.

In other words, you just couldn't get there.

Unless perhaps you could hire someone in Wolf Point, Montana, the nearest railhead, to make the trip to Vida in an open touring car, but in the spring, summer and fall seasons the road was often a sea of mud, and in the winter it was apt to be "drifted in" (a local colloquialism meaning the road is blocked with snow drifts) with the temperature standing at thirty below zero.

Here E.E. Krebsbach is pictured operating KGCX's first transmitter in 1926 at Vida, Montana.

Vida's inaccessibility caused visits of the District Radio Inspector (whose home base was Seattle) to be rare, although he was supposed to make an inspection of the station every six months. About 1928, however, Krebsbach received a telegram re-

questing that he meet the Inspector's train at Wolf Point the following morning at 9 A.M. Hurried long-distance telephone negotiations by Krebsbach arranged for a First Class operator to arrive at Wolf Point on an 8 A.M. train and the trio (Owner, Engineer, and Government Inspector) drove out together to the First State Bank of Vida, where the Inspector retired to another room with his equipment to make certain tests after leaving instructions to turn on the transmitter and to transmit a musical selection. He heard plenty of carrier wave, but no modulation whatsoever. Understandably flustered by the presence of the Inspector, Krebsbach had forgotten to remove the receiver hanging from the converted telephone-microphone, which short-circuited the mike and prevented any music from being broadcast. This difficulty was corrected, only to have the RI discover that KGCX was regrettably occupying a position on the radio dial twenty-two kilocycles away from the spot assigned to it by the Department of Commerce in far-off Washington, D.C. Since contemporary broadcasting stations are now required to maintain their frequency within twenty *cycles*, this was an error roughly equivalent to a London-bound jet landing in Capetown through an error in navigation. The Inspector's last words before boarding his return train to Seattle were, "I set your frequency—now don't fiddle with it."

In 1929, the station received permission to move to Wolf Point (population 2,500) contingent upon increasing its power to 250 watts. Mr. Krebsbach mail-ordered the required parts for the new transmitter and as a promotion stunt, displayed the various components of the new transmitter-to-be in the show windows of Wolf Point's stores. Even the local Chinese restaurant got into the act; the big plate transformer made a fine prop against which to lean the fly-specked menu.

Bert Hooper, Chief Engineer of CKCK in Regina, Canada was summoned to Wolf Point to assemble the new transmitter which he did in three days and three sleepless nights.

It looked it.

Hooper traveled to Wolf Point by means of an open cockpit Tiger Moth airplane, leaving Regina on a Sunday, which was a windy, gusty day so typical of the upper Midwest. It was necessary to have a man hanging on each lower wing of the aircraft to steady it until it gained speed for take-off. Navigation on the flight consisted of flying low enough to read the station names on the prairie railroad depots. Upon reaching the International Border a stop was, of course, mandatory to comply with the requirements of Customs and Immigration laws. However, the actual Boundary itself does not, in the subject area, consist of an impenetrable fence and a gate with barber-pole stripes as depicted in the movies. Rather, it consists of nothing but open and endless prairie land, marked every half mile with a concrete post and with Russian thistle "tumbling weeds" blowing back and forth from one country to the other in utter disregard of protocol. In those days, the Border officials were not stationed at the Boundary itself but rather at the nearest town to the border, which in this case was Scobey, Montana, some sixteen miles south of the International Line. Since Scobey, or for that matter, no other town in the area had an airport, a handy cow pasture was used as a landing field. In landing, the plane narrowly missed several holes excavated by gophers and arrangements were made to avoid such a stop on the return flight by an agreement with the border officials that flying twice around the Scobey water tower would constitute sufficient identification.

ONCE around would have been more than enough, since unidentified airplanes were sighted in that area and era only slightly oftener than Halley's Comet.

While Scobey had no airport, it did have two airplanes, owned by nearby farmers who agreed to escort the Canadian plane to a safe (?) landing field in Wolf Point. Now let Mr. Hooper continue the story as related in a recent letter to the author: "There were two Jennys (American and Canadian World War I training planes which two farmers had bought in Minneapolis for $50 each) that took off with us from Scobey to guide us to Wolf Point. One pilot wore a brilliant red silk shirt and the other pilot a brilliant yellow one. They flew alongside us on the

left side. With the up and down air currents, one minute we were looking down at them in their cockpits and the next moment they would be above us. Those Jennys were equipped with OX 5 water cooled engines and were a bit slower than us so we had to throttle back. It was a wonderful sight. . .We collected the various components which Ed (Krebsbach) had placed in the various store windows for advertising and I went to work. The pilot, Ted Holmes, was anxious to get back to Regina, so I worked around the clock until nearly daylight, around 3:15 A.M. Wednesday morning. Just missed a herd of cows in taking off, and to avoid them (we didn't see them until it was almost too late), Ted pulled the stick back into his stomach and we missed the power lines by an inch. We got back to Regina about 6 A.M. The Moth was equipped with an inverted six cylinder air-cooled engine of the latest English type and we could do all of 90 mph. I still think of those farmers and admire them for their nerve in buying two surplus training planes for $50 and flying them to their farms in Montana from Minneapolis. No licenses were required in those days. Must admit I did a lousy job in building the transmitter, but if I could have had a night's sleep and more time, I could have done a much better job. The plane was needed back in Canada to fly somewhere to pick up a sick person and fly him to a Regina hospital.'" (Author's note: Mr. Hooper did an *excellent* job, considering the very short time he had available to build a complete broadcasting station. The wonder is that he could do it at all in three days. The transmitters he built for CKCK were absolutely beautiful in appearance and performance. The $50 purchase price of the war-surplus airplanes referred to included three flying lessons. "Graduation ceremonies" from the miniscule flying course consisted of a handshake from the instructor who then pointed in a generally west by northwest direction and said "Montana is thataway.")

It will be related later in this story what excitement was caused in the towns of the area by an airplane circling overhead. It is easy, therefore, to imagine the carnival atmosphere instantly created in Wolf Point that hot and dusty Sunday afternoon when

TELREX "CHALLENGER" LINE

Outstanding Performance at Lower Cost!

Featuring:

Balun Fed 5 Element TRI-BAND®
Model TB5EC/1KWP
10-15-20M Single Trans Line Array

only
$225.00
f.o.b. Asbury Park, N. J.

EXCLUSIVE TELREX CUSTOM FEATURES

- 49 lb of Educated Aluminum® gain 8.5 DB, Epoxied, hi-q, h-v ceramic capacitors, resonated traps.
- Custom machined, heavy wall sectionally coupled and reinforced, 2½" x 2" x 18' aluminum boom, dural, taper-swaged elements, through construction.
- Individual optimum spaced, optimum tuned reflectors provide 28 DB, F/B on 10, 15 & 20 meters.
- Patented broad-band, encapsulated balun supplied.
- Stainless steel electrical hardware, heavy-duty cadmium plated steel tiltable mounting plate.
- Survival rating 110 mph, power 1KW peak rain or shine!

At selected dealers. . .or order direct for fast personal service.

not only a single airplane, but *three* of them started circling the town with obvious intent to land.

Incidentally, Hooper had passed his First Class radiotelegraph operator's examination at age 15 while he was living in Vancouver, B.C. and employed there as a telegraph messenger boy. Shortly afterward, he arrived home for supper one evening to find instructions awaiting him to report as Radio Officer aboard a vessel due to sail at 8 o'clock that evening. An obliging tailor worked overtime to cut a foot or so off the trousers and sleeves of a Radio Officer's uniform to make it fit young Hooper, who was slight of build, and gold thunderbolts affixed to the telegraph company's cap completed his uniform. He rode his bicycle to the dock, arriving at 7:45 P.M., carried the bicycle aboard and in his haste, reported to the Captain with his right trouser leg still furled around his ankle and held in place with a bicycle clip, and became perhaps the youngest "Sparks" ever to sail the seas.

The new transmitter tried hard to look like the latest product of RCA, but (reflecting its hasty construction) the whole effect was touchingly like that of a small boy's drawing of his conception of what a transmitter looks like.

It worked fine.

A tragic note in the history of the station occurred when an operator was electrocuted when he tried to replace a filter condenser in the high voltage supply without interrupting the program.

One of KGCX's more dramatic services to its listeners was to warn ranchers of the area when the nearby and treacherous Missouri River was on one of its rampages. Ol' Big Muddy has a nasty habit of changing its channel without warning, and in the spring, it often piles up chunks of ice, some as large as an automobile, with resultant flooding behind the ice jam.

Basketball was, and still is, a leading divertisement in the small towns of the upper Midwest during the long bleak winters, which hardly ever last more than seven or eight months. (An old cliche in the region has it that the climate of the area can be described as being eleven months of winter, one month of poor sledding, and thirteen months of wind.) Once, when Wolf Point High School was playing Poplar, Montana, the gymnasium was filled to absolute capacity by an enthusiastic crowd. KGCX's announcer, unable to gain entrance, had to borrow a step-ladder and peer through a transom to watch the game and broadcast the play-by-play account. When Wolf Point reached the finals in the state basketball tournament, local pride was outrageous and coverage of the final game was demanded of and provided by KGCX. A telephone was set up on the playing court at Great Falls, and a reporter relayed an account of the game to an announcer in Wolf Point who broadcast the game. One ardent Wolf Point fan, unwilling to wait for the broadcast version of the game, slipped unnoticed into the KGCX studio and was monitoring the reporter's account of the game on one of the station's extension telephones. When he heard the final score he shouted "WE WON" so loudly it blasted the transmitter right off the air. It was an hour before repairs could be made and the station could give its listeners the final story of the game.

One Saturday evening when the Krebsbach's were out of town (when the cat is away, etc.), an out-of-state dance orchestra (Duke Snyder and His Happiness Boys) which was barn-storming the area, dropped in at KGCX to provide some live entertainment. With the aid of a large supply of Montana moonshine, the Boys lived up to their name, and along with the technician operating the station, became progressively Happier as the evening wore on, and stayed on the air all night, a distinct departure from normal station policy. The hilarity knew no bounds and as the percentage of alcohol in the blood of the musicians increased, so did the tempo of the music. The human nose can detect and classify over 16,000 odors. Whether alcoholics can smell the fusel oil in liquor from afar or whether they are unerringly guided to a source of free liquor as surely as the honey bee is directed toward the nectar of the flowers by some not-yet-understood sixth sense, is as yet unknown, but in any event, several of the town lushes soon increased the size of the party. Large platters of fried oysters, fetched from the nearby Hotel Sherman, supplied the

calorie energy to keep the festivities going at full blast until they were reluctantly stopped on Sunday morning with fond farewells (performed as only a drunk can) on the part of all concerned, *only* because of the necessity for the station's engineer to run in a broken-field stagger that would have delighted the late Knute Rockne with the station's only microphone to one of the town's churches to cover a regularly scheduled Sunday morning church services broadcast. Some of the local merrymakers, stoned beyond ambulation, remained draped over the studio chairs and leered glassily at all comerss, while the orchestra retired to its sway-backed bus, which had a particularly apt-to-break-down-any-moment look about it, to sleep it off in time for their evening performance.

In Wolf Point, the station was associated with an oil company and located in that firm's service station. The clatter of a tire iron, unfortunately dropped on the concrete floor when the mike was open, would occasionally assail the ears of KGCX's listeners. Nevertheless, the station continued to fill a need in the area and in 1936 was granted a power increase to 1,000 watts.

KGCX dominated the air in its domain in more than one way during the late Twenties, since the oil company maintained (as a public relations device) an airplane which roamed over an area a couple of hundred miles in all directions from Wolf Point and which had the box-car size letters "KGCX" painted on the underside of the lower wing. As previously intimated in this story, the appearance of ANY aircraft in the area's sky was cause for great excitement and if it landed, the pilot NEVER had to walk into town, since shortly after landing he and the airplane would be surrounded by a crowd of the townspeople, who had driven out for a closer look at the flying machine and the Superman who could actually make it fly. The pilot, a somewhat taciturn individual who was reported to have laughed aloud once in 1919 or thereabouts and who was cross-eyed beyond any hope of surgical correction, occasionally cracked up the plane upon taking-off or landing and such an occurrence was, of course, THE thrill of the summer for the village, surpassing in excite-

Integrated Circuits

30 MHZ ELECTRONIC COUNTER

MULTI-FUNCTION – AC OR BATTERY – CRYSTAL ACCURACY – 5 DIGITS – AUTOMATIC DECIMAL POINT – LOW VOLTAGE NUMITRON READOUTS.

Measures frequency, period, ratio. Has scaler and marker outputs, external standard input. One mhz crystal oscillator time base with adjustment for standardizing with WWV. Automatic and manual control of display time and gate. Self test feature.

SENSITIVITY: 100 mv rms, 25 hz to 25 mhz; 500 mv, 10 hz to 25 hz; 200 mv, 25 mhz to 30 mhz. Maximum input, 50 v rms or 200 v peak AC plus DC. Input impedance approx 20k ohms shunted with 40 pf. Has input gain control. Ratio input (rear panel) 200 mv rms, 100 khz to 20 mhz.

TIME BASE ACCURACY: Room temperature 1 mhz crystal standard. Aging rate, ±1 ppm/week. Temperature stability, ±5 ppm 50 to 90 degrees F.

RANGES: FREQUENCY – four gate times, .001 sec to 1 sec. Decimal point indicated for kilohertz. PERIOD – three standard frequencies counted: 10 khz, 100 khz and 1 mhz. Decimal point indicated for milliseconds. RATIO – 100 khz to 20 mhz. Resolution selected by range switch. SCALING – 100 khz to 20 mhz. Division in decades from 10 to 1,000,000, selected by range switch.

MARKER OUTPUT: Fast rise square wave; 1 hz to 1 mhz in decades selected by range switch. Output is 4 volts open circuit, .2 volts into 50 ohms. Harmonics to hundreds of megahertz for receiver calibration.

BATTERY OPERATION: Terminals provided for 9 volts or 12 volts, can be operated from cigarett lighter socket for checking mobiles. Current is 1.5 amperes. Use with 8 or 9 volt battery pack for portable operation.

ment and over-the-backyard fence conversations even such great events as the visit of the Yankee-Robinson Railroad Circus With 500 People And 200 Animals, or the erection of the tent for the annual Chautauqua. The writer remembers attending something called a "rally" with his father at the site of an oil (?) well near Mohall, North Dakota, at which A.C. Townley, a Huey P. Long in microcosm, was the attraction and who arrived via airplane, which "buzzed" the crowd for dramatic effect before landing. To be able to shake hands with Townley was, for many a farmer in attendance, worth a trip ten times the distance. Upon being queried as to whether he was successful in shaking hands with the Great Person, one farmer was heard to reply, "No, but I TOUCHED his sleeve." Doughnuts and coffee, the latter conveniently heated with the bona-fide natural gas genuinely issuing from the well, were served following which samples of oil were extracted from the well (in tomato cans lowered on a string) to further on-the-spot sales of oil stock by the promoters. The great advantage of the well in question was that it produced oil already refined. A digression to include the Townley story was made only to assure the reader that had it been advertised merely that an airplane would be on hand, with rides going for a dollar a throw (without any celebrity being present), a large crowd, albeit not as huge, would still have attended. Thus the choice of an airplane as an advertising gimmick for both the oil company and KGCX was a brilliant one.

KGCX's antenna actually spanned the main street of Wolf Point, with the transmitter- studio- service station building and one antenna tower on the north side of the street and the other windmill type tower situated in a park-like setting on the south side of the street. This arrangement caused the maximum signal to be radiated in an easterly and westerly direction, directly at the most populated areas of the world. Too, the "flat-top" antenna (a type no longer used these days) was very conducive to the production of sky-wave signals which might be reflected back to earth from the Kennelly-Heaviside layer of the ionosphere thousands and thousands of miles from the little Montana town in which they were generated. In those embryonic days of radio, there were few stations on the air and consequently little or no interference between stations. Therefore, once the signal was started on its way from Wolf Point, there was nothing to stop it and it might fall back to earth in Tokyo or Tangiers or Tampa, depending on "skip" conditions and Mrs. Krebsbach mailed out many a printed Official Confirmation postcard from KGCX upon frantic requests from DX listener hobbyists living thousands of miles distant from Montana. It takes but little projection to place oneself in their shoes and imagine their fascination with such an exotic-sounding name as *Wolf Point, Montana*, bringing visions of timber wolves, Indians astride Pinto ponies attacking the military outpost, etc., to the mind of a listener, for example, in New York City who had never been west of Philadelphia. Remember, this was back in the Twenties and it wasn't a great span of years since such events had actually occurred in the area in question.

The unusual placement of the antenna towers caused hardship for a KGCX relief operator who arrived in Wolf Point via evening train at the height of a Montana blizzard. (It is useless to try to describe to those readers who have spent their lives in Southern climes what carnival Mother Nature engages in during these prairie storms, which usually claim the lives of several persons each winter. Suffice it to say that visibility is often cut to five feet or perhaps less.) This engineer, now an official of the Federal Communications Commission, located the "wrong" tower (the one in the park) and spent a freezing and fruitless half hour in the storm searching for the nerve center of the station. The possibility that KGCX was literally "working both sides of the street" never occurred to him. With all stores closed (what manner of customer would venture out in such weather?) no one was around to help the lost engineer and it was only by sheer accident that he stumbled into the other tower across the street and into the safety of the transmitter room.

Sparse population in the Wolf Point area, coupled with adverse business there, precipitated a financial crisis for the station in the

early Forties. With total station income for the year 1941 down to only five hundred dollars, it was obvious that *something* had to be done, and quickly. Eyeing a map of the area, Mr. Krebsbach wisely decided that a move to Sidney, Montana (population 5,000) with establishment of auxiliary studios in Williston, North Dakota (population 10,000) was the solution, and the Federal Communications Commission agreed. The move was accomplished in 1942. A complication arose when a major piece of the equipment which had always performed beautifully in Wolf Point, stubbornly and positively refused to work at all in Sidney.

In 1948 KGCX secured another power increase which required the erection of a second tower to protect another station hundreds of miles away from interference by KGCX. A consulting engineer was imported to Sidney to properly locate the new auxiliary tower. After much computation with his slide-rule, he selected the exact spot and the big job of erecting the two-hundred feet high structure was completed. When the last turnbuckle was tightened on the last guying cable, he dusted off his hands and stepped back with a smile of satisfaction to admire his work. As a final-final check, he again consulted his slip-stick. Gradually his eyes opened wider and wider until they approached the size of Satsuma plums, realizing that he had made a monumental error with the result that the whole tower had to be taken down piecemeal and re-erected at a spot some twelve feet away.

Some years later, the tower came down again (although considerably faster) with the suspected help of saboteurs.

During the Fifties, KGCX employed an announcer who, like the late Jack London's character in *Burning Daylight*, attempted to burn the candle at both ends by adopting a daily schedule of announcing all day and doing all night what comes naturally to young men. While the spirit was willing indeed, the flesh sometimes revolted from lack of rest, and the strains of Debussy's *Clair de Lune* or other soothing music from the studio speaker occasionally dropped the fledgling announcer off into the kind of sleep bordering on that from which there is no awakening, with the result that KGCX's

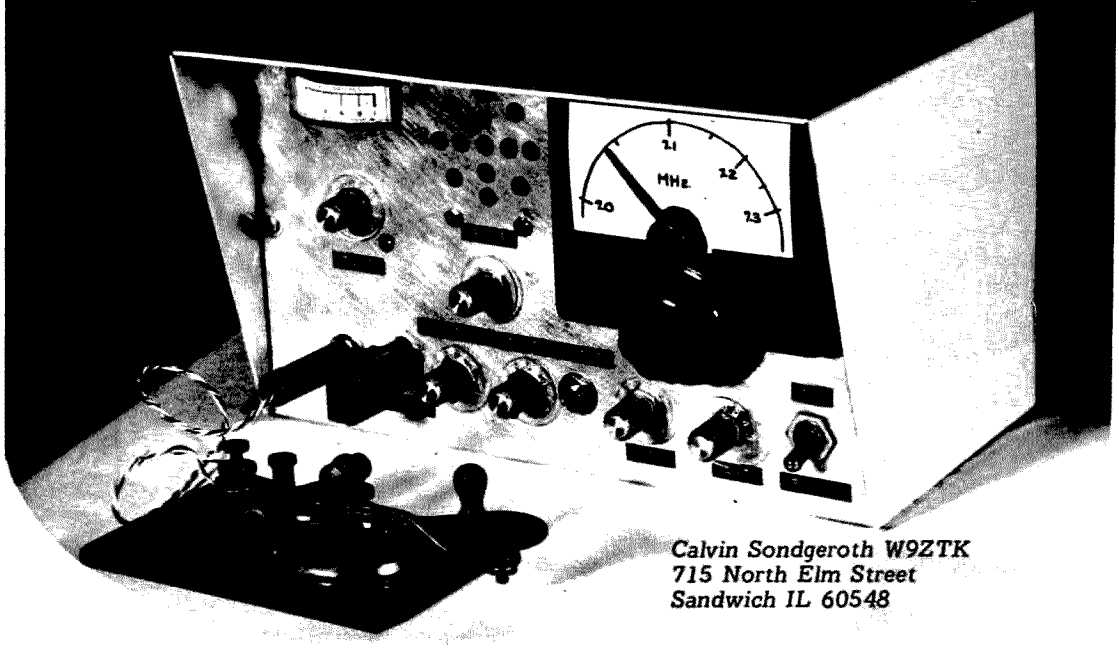
slot on the radio dial became deathly and apparently permanently silent. On an automobile trip a hundred miles or so distant from Sidney, with his car radio tuned to his favorite station, Mr. Krebsbach noticed this state of affairs and (apparently considering it to be somehwat less than ideal) made haste to the nearest town and the nearest telephone to correct the situation. The thoughts of Mr. Krebsbach during the comatose announcer incident are not known to this writer, but I am sure his fine Christian faith remained unshaken, in contrast perhaps with that of The Poor Sisters of Perpetual Adoration, who were recently bilked of nearly two million dollars in a Texas oil scheme and who may now be possibly at least a nickle's worth less perpetually adoring.

The original KGCX transmitter has been lost in the shuffle from town to town. Still preserved, however, is the 32 v to 1,000 v motor-generator (which provided the high voltage for the type 210 final tube) its armature frozen fast, never again to help waft the music of the A & P Gypsies into the blue Montana skies.

The $125 investment in the original transmitter has paid off handsomely; this writer estimates that KGCX is currently worth at least a third of a million dollars and perhaps more.



With comic incidents long past, modern equipment operating dependably, and with financial problems solved, the seven and one-half watt baby has grown into a powerful five thousand watt giant which blankets a large area with its Mutual network and local programs.

Fortune has smiled twice upon Wolf Point since, for the second time, it had a radio station thrust upon it when, in 1957, after business conditions had improved there, Mr. Krebsbach returned to his old stamping grounds after an absence of fifteen years and built KVCK there, a one-thousand watt sister of KGCX.

Mr. Krebsbach, although in declining health, continues as this is being written as owner and General Manager of KGCX and deserves the heartiest of congratulations for building his station from a back-room hobby into the respected and important entity it is today . . . W6CXC

THE SST-I

solid state transceiver for 40 meters

Calvin Sondgeroth W9ZTK
715 North Elm Street
Sandwich IL 60548

This is the age of the transceiver in ham band operation. Although there are many medium- to high-power commercial SSB packages available with self-contained transmitter and receiver, there is not much to choose from for low-power CW work. This article describes a small unit which is solid-state and provides about 2W input with a self-contained battery power supply. The receiver is simple but quite effective for CW work, and its performance matches that of the cheaper superhets. All the components are readily available and no special parts were used in the design. Since the transmitter is crystal-controlled, this little rig would make an ideal beginning station for the Novice.

Receiver

A QST article by D. DeMaw (May 1969) described a solid-state direct conversion receiver using an RCA linear integrated circuit. This design requires a minimum of parts for CW (and sideband) reception since the incoming signal is mixed with a local oscillator at the signal frequency for audio output directly from the product detector. Although the selectivity is not as good as a superhet with i-f conversion, the results are entirely adequate for general operation. The receiver far outperforms any superregenerative set I have built, and I've tried many circuits.

The front end is double-tuned to prevent responses on strong signals outside the 40 meter band; two toroids tuned with a 140 pF double-section variable capacitor accomplish this, as shown in the transceiver schematic, Fig. 1. The incoming signal is lightly coupled to the IC product detector to prevent loading the input circuits, and the local oscillator uses an identical toroid in its tuned circuit. The oscillator circuit is tuned by a 50 pF variable with a small trimmer in series to adjust the bandspread to cover the full 180 degrees on the dial.

Audio from the detector is coupled out through a small transistor interstage transformer with a 10 kΩ potentiometer across the secondary as a gain control. A single stage of audio amplification precedes the audio amplifier, which is the push-pull audio section salvaged from an old transistor broadcast radio. This generates plenty of audio to drive a small loudspeaker (also from the BC set); and if just headphone operation is desired, the 2N3391A will provide enough output by itself.

The original article on this receiver used an audio bandpass filter between the detector and the audio amplifier. This had two large toroids and, in the interest of size reduction, a low-pass filter consisting of a single LC section provides adequate cutoff of high-frequency hiss and noise which is present without any filtering at all.

The inductance in the filter is the secondary of an interstage audio transformer shunted with a 0.1 μF capacitor to ground; this arrangement cuts off around 2000 Hz. The capacitance value can be adjusted to provide proper cutoff with the particular audio transformer used. The receiver is usable without the filter, but the high-frequency components in the detector output become annoying after an extended period of operation.

It will be noted that two 9V batteries are shown on the schematic to power the receiver section. This was done because the *rf–first audio* portion used a negative ground system while the push-pull output of most of the small imported radios uses a positive ground system, and the output transformer secondary has one side tied directly to ground. Various ground arrangements were tried to eliminate one of the batteries, but the two-battery setup was finally decided upon. This does split up the load on the batteries somewhat and increases their life. The rf portion draws about 15 mA and the audio section anywhere from 10 to 50 mA on strong audio peaks.

CW Monitor

A unijunction audio oscillator is included on the audio output module for monitoring while transmitting. The monitor output is fed into the audio output amplifier after the gain control, and the monitor level is set for suitable volume which is independent of the receiver volume control setting. Voltage for the monitor is obtained from the transmitter supply and it is keyed along with the transmitter.

The 100 kΩ resistor and the 0.01 μF capacitor in the emitter lead of the unijunction provide an audio tone of about 600 Hz; this can be raised by lowering the value of the emitter resistor if you prefer a monitor pitch of higher frequency.

Transmitter

The transmitter, crystal-controlled for simplicity, used three 2N697 transistors – two in the rf section and the third as a switch for keying. The keying switch was added to reduce the current through the key contacts, although it could easily be eliminated and the final connected to the negative supply continuously, since it does not draw any current without drive from the oscillator. The keying arrangement shown was a result of using the transmitter which had already been built when the transceiver idea came up.

The oscillator is connected in a Pierce circuit with the crystal between collector and base. The 1 kΩ potentiometer in the emitter controls the drive to the final. The oscillator collector uses a slug-tuned coil with a small link wound over the cold end to the couple into the final amplifier.

The final, operated without any bias, runs class C. It uses a *pi* network in the output circuit,

SWR Bridge and Meter Circuit

For tuneup while operating portable it was considered desirable to include some means of monitoring final collector current as well as some way of indicating when a match to the antenna was obtained, since random-length antennas are convenient. A small pilot light could be used to indicate relative current in the final, but the addition of the 0–1 mA meter and the swr bridge has proved its worth in the field.

Please Use Your Zip Code When Writing 73

The meter is set by a three-position switch to read either final-stage emitter current or forward or reflected power. For emitter-current readings, the voltage across a 10Ω resistor in the emitter lead gives a full-scale reading of approximately 100 mA with the meter specified. A 20 kΩ potentiometer is connected in series with the meter for swr measurements and must be set to zero resistance for final current indications.

The swr bridge is standard in design except for the two transistors added as dc amplifiers. They were found necessary to get indications with the low power output of the transmitter. The gain mismatch between transistors does not really allow the swr to be measured accurately, but a good indication of a proper match to a 50 or 72Ω coax line can be obtained by adjusting for minimum reflected power and maximum forward power. A two-section switching arrangement could be used to eliminate one of the transistors, thus providing more accurate readings. The bridge conductor is a piece of ¼ in. copper tubing; the pickup wires are of 14 AWG solid wire. The assembly is built in a small channel bent up out of aluminum sheet metal as shown in Fig. 2. In order to get readings with the bridge it must be mounted off the main chassis with an insulating spacer and the channel connected to ground via the coax shield on the input and output only.

Construction

The main housing for the transceiver is a Bud SC-3030, which is 6 x 10 x 7 in. This volume allows construction without crowding yet keeps the unit small enough to be easily portable. The transmitter is built on a separate minibox 2¼ x 2¼ x 5 in. and can be put together as a separate unit with a couple of leads provided for a crystal socket on the front panel of the main enclosure. The transmitter is mounted to the front panel by the key jack which has one side tied directly to ground. In addition, a barrier terminal strip was provided on the rear panel for connection of an ac power supply for fixed station work. The drive control potentiometer was mounted inside the transmitter since it is not adjusted in normal operation. The final amplifier transistor was mounted on a piece of .040 aluminum about 2 in. square which serves as a heatsink. Since the collector is connected to the transistor case, the heatsink must be insulated from ground.

A twice-size PC board layout for the receiver *rf--first audio* section is shown in Fig. 3. The integrated circuit is soldered directly into the circuit board, although a socket can be used. Don't be too concerned about damaging the integrated circuit. The one here had to be removed from the board once by cutting the leads above the board and remounted by soldering extension leads to it indicating that these little devices are really quite rugged. Without a proper unsoldering tool, it is difficult to remove the IC once it has been soldered in so a socket might be a good idea even though the board is not laid out for one.

To facilitate parts placement and circuit identification, the composite layout/schematic of Fig. 4 is included. This should help to speed your final assembly process.

The audio output amplifier from the discarded broadcast set was mounted on a small piece of Vector board along with the components for the CW monitor. Fortunately, the radio I dismantled had been built in two sections, with the audio stages on a separate small circuit board. Other radios might have to be operated on to get just the audio section to use in the transceiver. The input to the amplifier can be located by tracing down the leads going to the volume control in the original radio. The wiper arm on the control is connected to the input.

The receiver modules are mounted to a small subchassis which was extensively worked on with tin shears. It is made from a standard open-end 5 x 7 x 1½ in. aluminum chassis. The front is cut off to clear the controls on the front panel and the rest notched and cut where necessary to clear the main enclosure. A vertical shield was positioned across the transceiver between the receiver and transmitter, although this is probably not absolutely essential.

The subchassis provides adequate mounting space at the center (between receiver and transmitter) for the transmit-

THE BEST
2 METER
CONVERTER

Model 407
$39.95
ppd.

144-146 MHz in, 28-30 MHz out
or 146-148 MHz with a second crystal
Available at $4.95 each.

A full description of this fantastic converter would fill this page, but you can take our word for it (or those of thousands of satisfied users) that it's the best. The reason is simple—we use three RCA dual gate MOSFETs, one bipolar, and 3 diodes in the best circuit ever. Still not convinced?Then send for our free catalog and get the full description, plus photos and even the schematic.
Can't wait?Then send us a postal money order for $39.95 and we'll rush the 407 out to you. NOTE: The Model 407 is also available in any frequency combination up to 450 MHz (some at higher prices) as listed in our catalog.

*New York City and State residents add local sales tax.

VANGUARD LABS

Dept. H, 196-23 Jamaica Ave., Hollis, N.Y. 11423

ter batteries and the two 9V batteries are mounted to the rear enclosure wall with a homemade bracket of sheet aluminum. The 1.5V penlight cell is mounted on the swr bridge channel as shown in Fig. 2.

The swr bridge is mounted near the rear of the transmitter and the bridge channel is insulated from the main enclosure as mentioned above. Connection to the bridge should be made with small coaxial cable going to the transmitter *pi* network and the transmit–receive switch. Similar coax is used to connect the receiver and antenna connector to the switch.

The photographs show the general construction and panel layout used, but other builders may find other arrangements more desirable. The general layout is suggested as a logical one.

Adjustment and Tuneup

When the receiver is operating, the oscillator frequency is adjusted to cover 40 meters by alternately padding the tuned circuit with fixed capacitance and varying the trimmer in series with the main tuning capacitor to achieve the desired bandspread. By setting the trimmer, the entire

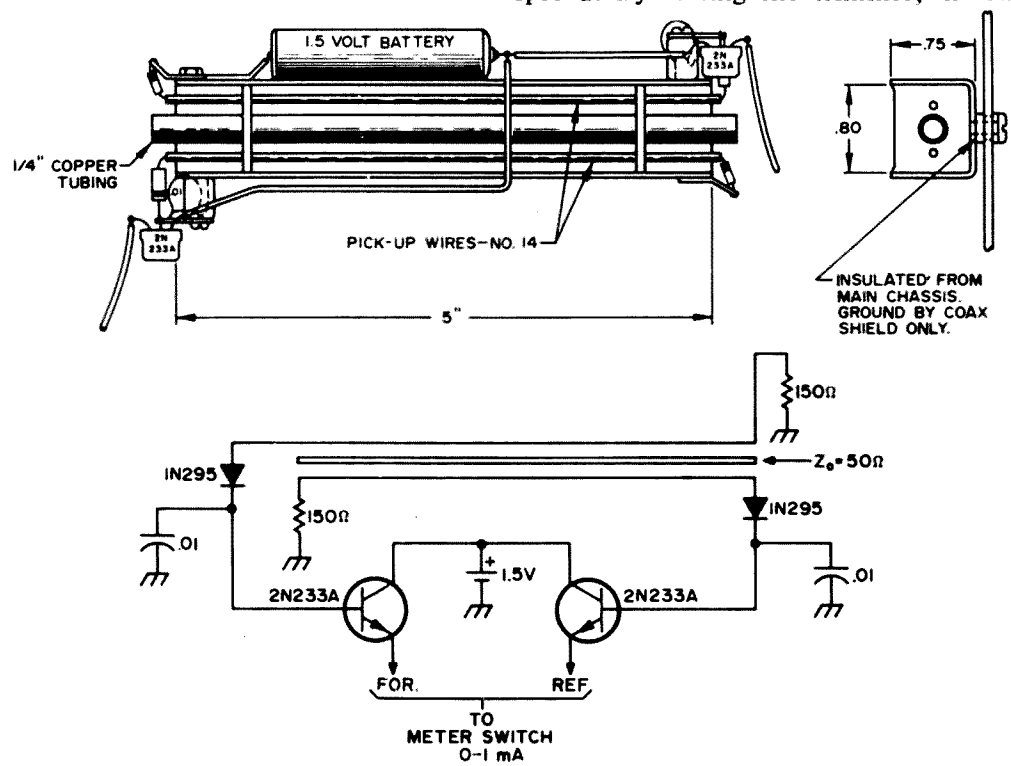

Fig. 2. Swr bridge assembly and placement data.

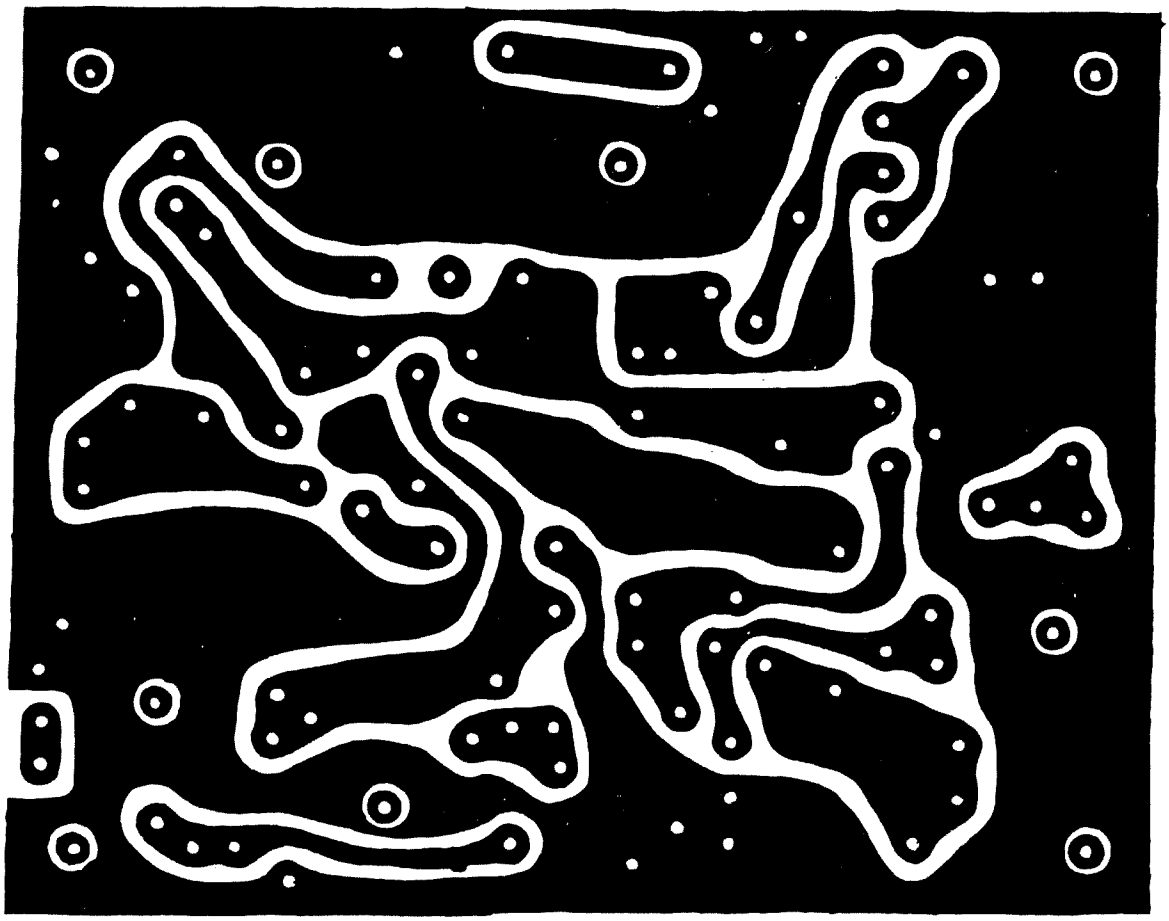

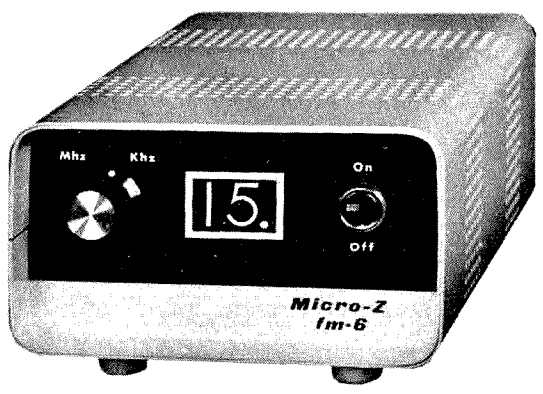

Fig. 3. Double-size PC board layout for the rf/af section of the receiver.

band can be tuned or the bandspread limited to just the CW portion. Other arrangements might give different bandspread, but the transceiver described covered the first 100 kHz of 40m over about half the dial and the other 200 kHz over the second half, which was felt to be about right and allowed for monitoring sideband as well as CHU just above the top band edge for time checks as an added bonus.

Some trouble with the local oscillator was experienced at first: Spurious responses were obtained, with 7 MHz appearing at several places on the dial. This indicated that the oscillator was operating at too high a level, which generated unwanted outputs. The two capacitors in series from base to ground on the oscillator determine the amount of feedback and the values were set as shown so that the oscillator provides just enough signal to beat against the incoming signal.

Digital Frequency Meter

- Monitors your "transmitted" signal
- Measures Khz and Mhz
- Operates with any exciter-transmitter (1 to 600 watts—up to 30 Mhz)
- Large-bright "Nixie" display

FM-6 Kit **$139.95**

Micro-Z Co.

Box 2426 Rolling Hills, Calif. 90274

The audio output section and the CW monitor can be checked by connecting the monitor to the transmitter supply and making sure that the audio tone is of the desired level and pitch.

When first tuning up the transmitter, it is a good idea to disconnect the final amplifier until the crystal oscillator is operating properly. The oscillator collector coil slug should be tuned up for proper oscillation and keying. With the final connected turn the drive control pot for minimum drive (maximum resistance) and switch the meter to read final emitter current. (The transmitter should have a dummy load connected during all tests!)

With the oscillator working, increase the drive to the final and adjust the oscillator coil slug and the drive control for around 100 mA of emitter current with 24V collector supply. This gives a little over 2W input to the final and is the normal level for CW operation. A 51Ω (1W) resistor makes an ideal dummy load and it should get warm to the touch after several minutes dissipating the output from the transmitter. A No. 47 pilot light can also be used as a load for indications of maximum output and should light to about full brilliance when the rig is properly loaded up and tuned.

When proper operation into a dummy load is verified, the transmitter can be connected to an antenna and the matching network adjusted in the usual way for proper loading. It is possible to QSY over 100 kHz of the CW portion of 40m without retuning either the crystal oscillator or final amplifier, with only a slight readjustment of the antenna coupler.

Results and Afterthoughts

Results with this little transceiver have

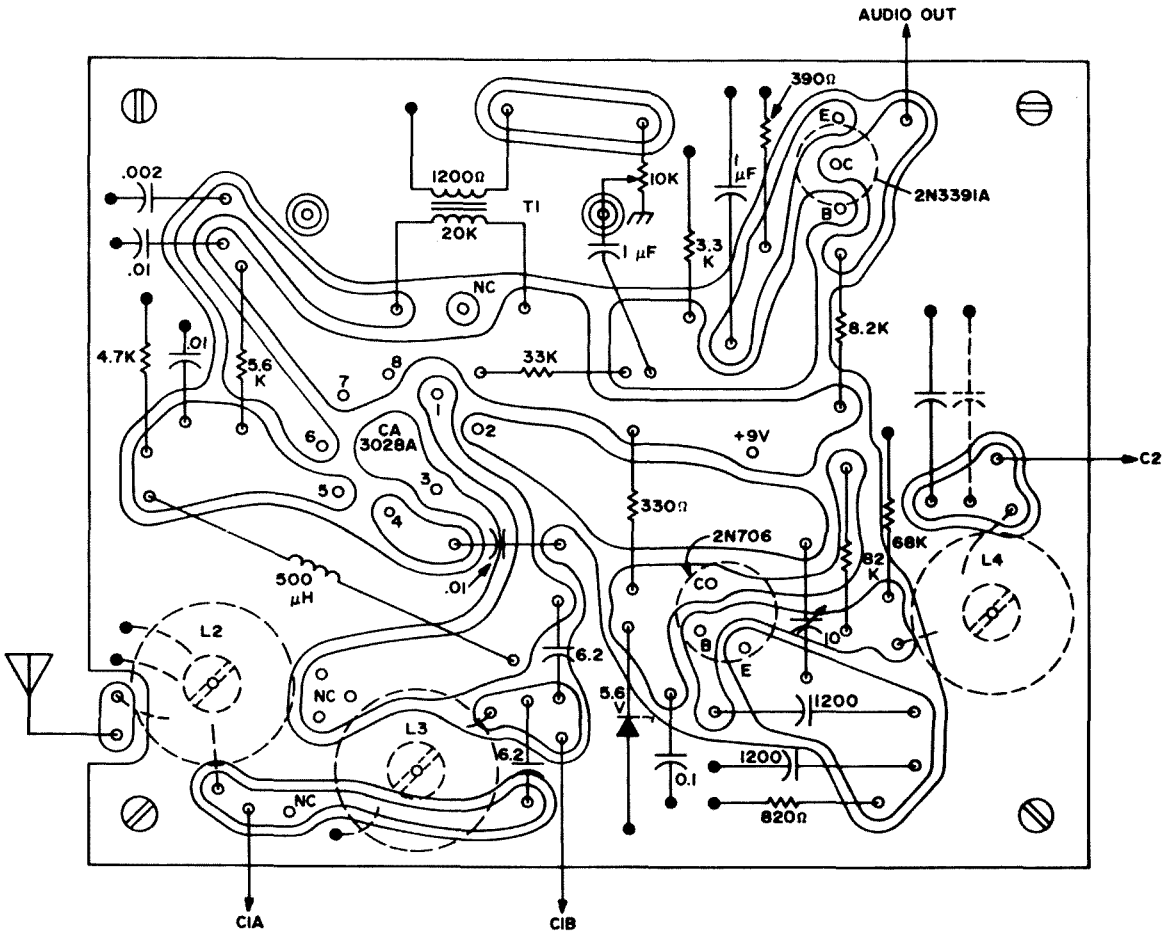

Fig. 4. This composite sketch shows positioning of components on the etched board.

been very good. A watt of power into the antenna may not seem like a lot to the kilowatt operator, but don't underestimate the punch of the signal. I have had stations at 400 miles during daylight operation insist on giving me a 599 report. In general, stations come back to the first call (unless you're covered up by a higher power station calling) and your contact probably won't know you are QRP until you tell him. Crystal control does limit the operating convenience somewhat with low power.

Since the receiver has an oscillator right on the operating frequency some will probably wonder why it is not used as a transmitting vfo also. The answer is that it can and if I were building this unit again I would probably include vfo operation. In fact, some checks were made using the receiver oscillator as a rfo with moderate success. However, the output of the local oscillator is quite low and it was necessary to provide a comple of stages of rather high gain to properly drive the transmitter. These tended to be somewhat unstable in operation and the vfo idea was abandoned, without too much work done in that direction. A conversion-type receiver would probably be better in this respect with the vfo operating at a frequency different than that of the transmitter.

With a suitable antenna coupler or matching network the rig will load into just about any piece of wire for portable work. Operation from the home station has been with a Windom antenna cut for 40m and fed with single wire. This still requires an L-network between the transmitter and antenna for proper matching. A coax fed dipole should work connected directly to the transceiver antenna connector.

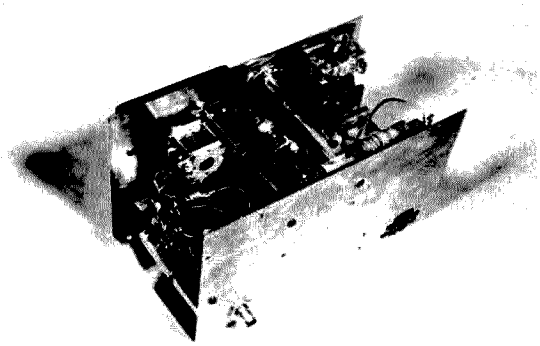

Photo showing shielding and construction of 40m transmitter and receiver in main chassis housing.

Receiver performance has been exceptional and sure beats using a regenerative set with its limited audio output and instability. Drift from a cold start with this receiver is practically nil and it can be used to copy sideband signals with no trouble at all. For CW work, a more selective audio bandpass filter can be used either in place of the low-pass filter inside the transceiver or in the headphone line. A couple of 88 mH toroids and some 0.5 μF capacitors will increase the selectivity markedly when connected as an audio filter. For general operation the filter is not necessary and it does prevent good copy on sideband signals.

With the addition of a balanced modulator, this setup could provide the basis for a simple little sideband rig using the audio section for the speech amplifier, generating a double sideband signal at 7 MHz.

Using currently available transistors, this little transceiver can be used to drive a class C stage to 15 or 20W for a little more signal, but at these power levels a battery of rather monstrous proportions is required; the 2W power level is just about right for the mercury batteries used. And 20W isn't really QRP anyway.

Table of Parts

C1 – 140 pF peri section, dual variable capacitor
C2 – 9–35 pF ceramic trimmer
C3 – Main tuning 50 pF variable capacitor
C4 – 365 pF broadcast variable
CR1 – 5.6V zener, 1N708 or equivalent
T1 – Interstage audio transformer 1.2–20 kΩ 6-T-12 PC (Allied Radio)
BA1, BA2 – 9V batteries
BA3 – 5V cell
BA4 – Two 12V batteries in series, Mallory TR289 or equivalent
IC1 – RCA CA3028A
L1 – 5 turns 28 AWG spaced over L2
L2, L3, L4 – 36 turns 32 AWG wound on .380 diameter toroid core (Arnold A4-380-125-SF)
L5 – 12 turns 28 AWG close-wound on 3/8 in. diameter slug-tuned form
L6 – 3 turns 22 AWG over B+ end of L5
L7 – B&W Miniductor ½ in. 16 TPI, 1 in. long
M1 – 0-1 mA meter (Emico Model 13)
Main tuning dial – Millen Type 10039 midget panel dial

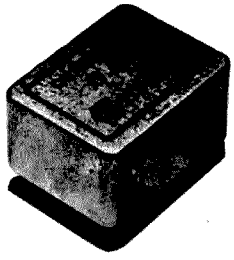
A LOW-COST RF WATTMETER

Marc Leavey WA3AJR
9412 Adelphi Road
Adelphi MD 20783

You say you just finished building that 2 meter rig and want to find out how much power you're running but can't afford to buy a wattmeter? You've been calling "CQ 80 QRP" all day with your quarter-watt wonder and nobody is answering? Then get yourself up, go down into the workshop, and build yourself a neato-keeno handy-dandy wattmeter.

If we are going to build a wattmeter, let's consider what we want. Accuracy and ease of calibration, as well as simplicity in construction are prime requisites. The meter described here is as accurate as components allow, and it's easy to build. The calibration is logarithmic, which means that a simple graph is possible, and easier than changing the meter scale.



For the mathematicians, I will present the formulas upon which this device is based, and ways of modifying it; for those of you who avoid math whenever you can, look at the graphs and skip these few paragraphs.

To spare undue complexity, assume 51Ω line – other values can be dealt with later. Perhaps the easiest parameter to measure, and one that is proportional to power, is rf voltage. A voltmeter can be made most easily with a series resistor and a 0–1 mA meter. Now let's plunge into the actual calculations.

Assume W is the full-scale meter reading in watts, Z is the line impedance, E is the voltage measured, I is the full-scale meter reading in amps of the basic meter, and R is the value of the series resistor in ohms. We know that the voltage (IR) is equal to the square root of "impedance times power," or 14.270V. Now, since the voltage and the current (.001A because the full-scale movement is 1 mA) are known, simple division yields 14,270. The resistor value, then, is 14.270 kΩ. The upper portion of Fig. 1 is a graph that will enable the nonmathematician to choose the value of the resistor for full-scale readings up to 4 kW, with 51Ω line and a 0–1 mA meter.

Why 4 kW with an amateur power limit of 1 kW? A look at the bottom half of Fig. 1 will explain. Although this is the calibration of the prototype, for 4W full scale, it will double for 40, 400, or 4000W. A half-scale reading, 0.5 mA, corresponds to 1W (1 kW, etc.). This spreads out the range below 1 kW for ease of reading and measuring.

Now get out that soldering copper and gas pliers, and build it. As the schematic (Fig. 2) shows, the circuit is a basic rectifying type rf voltmeter. The prototype was built in a small can of the plug-in-module variety that was scrounged from the junkbox. About the only critical part is the series resistor. The capacitors in the prototype were mica, but ceramic disks

CRYSTAL FILTERS

By KVG of WEST GERMANY

High performance 9 and 10.7 MHz crystal filters for SSB, FM, AM and CW application.
Small size (1-27/64" x 1-3/64" x ¾") perfectly suited for miniaturized solid-state equipment.

Filter Type	XF-9A	XF-9B	XF-9C	XF-9D	XF-9E	XF-9M
Application	SSB-Transmit	SSB	AM	AM	FM	CW

Matching HC-25/U crystals: 8998.5 (USB), 8999.0 (BFO) 9000.0 (carrier) 9001.5 (LSB). $2.75 each.

10.7 MHz filters for 20, 25 and 50 kHz FM channel separation. 8 pole type. . **$30.25** each.

SPECTRUM INTERNATIONAL
BOX 87G TOPSFIELD
MASSACHUSETTS 01983

RF MULTIMETER – 1 mv. to 1v. D-C and RF to 1 Ghz.; VSWR 1.35 & 3.00 full scale; 0 to 60 dB.; many other features: Model RFM-1.

VSWR BRIDGE SET – Precise swept frequency or cw VSWR measurement to 2 Ghz.; includes bridge, termination, and mismatches: Model RCS-1.

BROADBAND RF AMP – 30 dB. gain minimum 10 to 150 MHz; 10 dB. gain minimum to 500 MHz; noise figure is 6 dB. maximum: Model BBA-1.

PREMIUM RF AMP – Same as above but with low noise transistors and selected components; noise figure is 3 dB. maximum: Model BBA-1P.

BROADBAND DETECTORS – Coaxial RF detectors in BNC type male and female; high efficiency; 1 MHz. to 1 GHz. ± 1 dB. Model CRD-1,2.

PEAK-N-NOTCH FILTER – Tunable by front panel control from 100 to 2500 Hz.; 25 dB. peak or notch selectable by switch; unity voltage gain; will drive phones or small speaker: Model PNN-1.

EXTRA CLASS LICENSE
STUDY COURSE BOOK
HARDBOUND!

The Extra Class License Study Guide is now available in hardbound book form as a permanent addition to your radio library. This is the complete course that was published in 73, covering every technical phase of the new license exams for this highest class of amateur license. This also covers, in the easiest to understand form, just about every technical question likely to be asked on the First Class Radiotelephone exam.

This is the first study course ever published that is written so the newcomer to radio can understand it. With this book you can face the FCC exams knowing that you understand the theory and with no fear of rewritten questions.

Connection to transmitter with dummy load (see text).

reading, I = 0.0005, and calculate W for half-scale. Plot these two points at 1.0 and 0.5 mA on Fig. 1, and connect by a straight line, which you may extend the length of the graph.

Connection to transmitter with antenna connected.

Install the meter through a coaxial tee at your antenna connector, or through some other predetermined means, and terminate with a dummy load. The one seen in the picture is three 150Ω resistors in parallel, dipped in epoxy, shielded with a copper braid, and installed on a BNC plug. Apply power and read the meter. That's it! The meter can be used with an antenna if your swr is below about 1.2:1.

So what did I promise? A low-cost, rf wattmeter that is inexpensive enough for the Novice, practical and useful enough for the General, and "Extra" accurate. Go raid the junkbox, and add a worthwhile piece of gear to your shack.

Calibrate that Calibrator

Most modern receivers and transceivers in use today rely upon a 100 kHz crystal oscillator to calibrate the tuning dial. While some of the calibrators are built in, others come as outboard accessories. In any event the operation of each is the same.

By this time we all probably know what "zero beating" is. The 100 kHz oscillator in order to serve as a calibrator must be "zeroed" to some standard frequency such as the WWV carrier frequency on 5, 10, 15, 20, etc. MHz. With a CW or AM receiver, we can very easily tune through the zero beat point. On SSB receivers because one of the sidebands is missing we can only hear the one side as we approach zero. The other side of zero is greatly attenuated and may possibly not be heard at all. To further complicate matters for us in trying to calibrate the 100 kHz oscillator, as we can only hear down to about 20 Hz, we can't zero in any closer than this. Leaving the receiver at this point, we next turn on the 100 kHz calibrate oscillator. After a suitable warm up period, we turn the tune control of the oscillator and again adjust for a zero beat condition against the WWV frequency. With this method of calibration we have several possible sources of error. First in zeroing WWV with the receiver beat frequency oscillator and then zero beating the 100 kHz calibrator against the bfo. Each of these adjustments is limited to the lower limit of our hearing range, as well as the fact that we are obtaining the zero beat at a relatively low i-f frequency.

A more accurate method of calibrating the 100 kHz oscillator will now be discussed. After the receiver and calibrator oscillator have been warmed up for about 30 minutes, tune in WWV on a frequency that produces a fairly good, steady signal. Adjust the tuning for maximum reading on the S-meter. Having tuned in WWV, turn *off* the beat frequency oscillator. Now turn on the 100 kHz oscillator that is to be calibrated. If a harmonic of this oscillator is fairly close to the WWV frequency, a beat note will be heard. At this time adjust the calibrator "crystal tune" control and the S-meter will start pulsing from a maximum to a minimum value. The closer you get to dead center the slower the pulsing action will become. It is fairly easy to come down to 1 pulse per second with this method. If your receiver doesn't have a meter, you can also hear this pulsation very clearly. In any event you would always tune for the slowest pulse rate.

Note that with this method we have adjusted the calibrator frequency harmonic directly to the WWV carrier rather than to a low i-f. We have eliminated one zero beating step, and this, together with the fact that we are obtaining the zero beat at a much higher frequency, will provide greater accuracy.

Having described the method, here are a few points of general interest:

1. Before attempting any calibration let the equipment heat up for at least a half hour to stabilize.

2. After tuning in WWV, wait until the 400 Hz modulating tone goes off before adjusting the calibrator. If not, you may find later that you zero beat the 400 Hz instead of the carrier frequency!

3. The levels produced in the receiver by WWV and the calibrator oscillator should be about equal to produce a good beat between the two frequencies.

4. Use the highest WWV frequency that will produce a good, stable signal in the receiver. Certainly a 1 pulse per second beat at 20 MHz will provide greater calibration accuracy than 1 pps beat at 5 MHz or better yet than 455 kHz! The accuracy will be considerably greater and it is no more difficult to come by.

Mitchel Katz **W2KPE** ■

STUDY GUIDE GENERAL CLASS LICENSE

Part IV: Got a Match?

Nope, we're not discussing the relative health hazards involved in tobacco, gasoline, and kitchen matches – even if we will be using many of the same words. In this chapter, we're concentrating on three major subjects: impedance matching, how filters operate, and transistors.

Up to now, we have established the basics of ac and dc circuit theory to sufficient depth to permit us to cover this broad range of subjects this time. While the subject range is broad, it accounts for only three questions on the FCC's official study list. They are (numbers, as always, are those appearing in the list):

7. What is impedance matching and why is it important?

23. How can transistors be used in electronic equipment? What is the beta of a transistor? Compare the elements of a transistor to a vacuum tube's.

42. What do high- and low-pass constant-k filter circuits using balanced and unbalanced pi- and T-sections look like?

For starters, we'll attempt to discover why and how impedances are matched. This exploration may shock a few old-timers as much as it shocked us during the research stages – because the "why" is, it turns out, rather different from the reasons most popularly believed.

Then we'll turn our attention to filters, with two question: *What is a filter?* – which should bring some order into the names applied to filters as well as uncovering their various uses (and many disguises), followed by *How do filters operate?* This second query which will examine the means by which the more common circuits accomplish their purposes.

With matching and filters accounted for, we can take up transistors – but to provide some groundwork in this area, we'll first explore amplification and bring all kinds of amplifiers into our picture of circuit theory. With that established, we will be in much better position to examine the question *How do transistors amplify?*. This will take care of the other transistor details involved in the FCC question as well.

It's a big bite of information this time, so let's get right into it. Take a deep breath, and we'll be on our way. . .

Why and How Are Impedances Matched?

In previous chapters, we have put together a number of different types of electrical circuits, building each circuit up from different kinds of components. In every circuit, we have had a "generator" or power source of some sort, together with the passive components which make up the rest of the circuit.

In examining these circuits, we have seen that the action of the entire circuit depends upon the relations between the various components which make up the circuit. If any single component is changed, the circuit's action changes. In other words, for any circuit to act as its designer expects it to, every part of the circuit must be what it was intended to be.

Now we can take any single component, or a group of several components which go together to make up a subcircuit, and draw an imaginary line separating that part of the complete circuit from the rest. Having done this, we can name the part of the complete circuit which contains the power source as the *source* and the other part of the circuit as the *load*. Doing this does not change the fact that it is one complete circuit, so that every part must still be what it was intended to be for the expected circuit actions to occur.

In particular, any variation of component values or types in the *load* will

affect operation of the *source* just as it would when we looked at the whole thing as being a single circuit.

In practice, almost every electrical or electronic device is an *incomplete* circuit. Only the simple circuits which we study to learn how things work are complete and self-contained in themselves. A factory-built transmitter, for instance, does not come from the store complete with its own 117V ac generator, nor is the antenna a part of the rig as you purchase it. For the transmitter to operate, you must connect it to a power source, and you must provide an antenna as the rig's load.

The importance of impedance matching stems directly from the fact that all practical circuits are incomplete, and must be completed by the user in order to operate. To complete the circuit, the items connected by the user must "match" the equipment – and yet the equipment designer cannot possibly predict exactly how every possible user may connect his product.

The situation is saved by the fact that impedance can be considered to be a constant factor. That is, any circuit which exhibits a specific impedance characteristic can be substituted for any other circuit which has the same impedance characteristics. This is sometimes called the *black box* theory; the name comes from the fact that if you conceal a circuit inside a black box which cannot be opened, the only method anyone has of determining what is inside the box is to measure its performance at the terminals which connect it to the outside world – and all circuits which show the same characteristics in such measurements can be considered to be identical to each other no matter what is actually inside the box.

By specifying the required impedance levels for the power source and the load, then, the equipment designer can assure the user of his product that it will perform as intended.

In its most-used sense, the phrase "impedance matching" means simply providing the required impedance level, and says nothing about what this impedance level may be. In some cases this may mean providing a high impedance compared to the source, and in some cases it may mean a low impedance. The important thing is that the *required* impedance is provided, and it's up to the equipment designer to say what this required impedance may be.

However, impedance matching may also mean other things, and that is where the confusion comes in. One of the most respected ham radio reference books puts it – incorrectly – this way: "It is possible to show that any source of power will deliver its maximum possible output when the impedance of the load is equal to the internal impedance of the source. The impedance of the source is said to be *matched* under this condition."

The error is easy to see if we take the circuit of Fig. 1, in which the impedance of

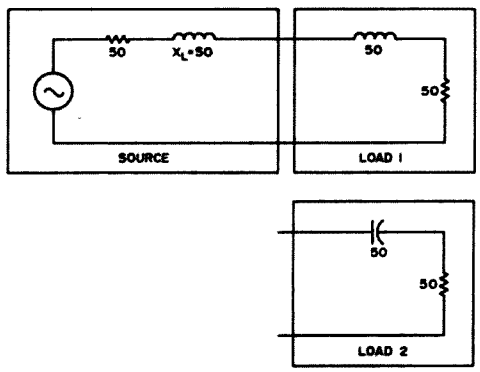

Fig. 1. Differences between "image impedance" matching and "maximum power transfer" matching are shown here and discussed in text. Using "load 1" follows the image-impedance rule, in which load's impedance is exact duplicate of source impedance. You can see that reactance is present, reducing power from the maximum possible. Use of "load 2" follows "maximum power transfer matching" rule in which resistances match but reactances are of opposite polarity. Reactance then cancels, and power is at maximum.

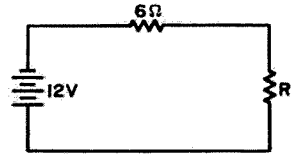
the source is 50+j50 ohms (inductive reactance as well as resistance). If we match this with a 50+j50 ohm load, the total impedance applied to the generator will be 100+j100 ohms. The 100Ω resistance is accompanied by another 100Ω of inductive reactance, and if the generator supplies

100V rms we will get a current through the resistance of only about 700 mA. This 700 mA through the 50Ω resistance of the load will develop a potential of 35V and the power dissipated in the load resistance is 700 mA (0.7A) times 35V, or 24.5W.

If we change the load impedance to 50-j50 ohms, though, to make the reactance of the load equal in amount but opposite in sign to that of the load, the reactances will cancel each other. The circuit is now series resonant. Net impedance seen by the generator is 100±j0 ohms, and 1.0A flows. This 1A develops 50V across the resistance in the load, or a 50W dissipation.



The handbook's statement is incorrect, but several generations of amateurs take it for truth. The *correct* statement is that maximum power is delivered when the resistance components are equal in amount but opposite in sign. This form of impedance matching is known as "maximum-power-transfer" matching. Of course, if neither source nor load involves any reactance, this boils down to equal impedance.

The equal-impedance type of matching defined in the quotation from the handbook is known to engineers as "image impedance" matching, because each of the impedances involved is the exact image of the other. While it does not guarantee maximum power transfer if any reactance is present, it is often employed because of its simplicity.

And as we have already noted, if pains are taken to eliminate all reactance from both the source and the load impedance, the image-impedance match and the maximum-power-transfer match are identical.

An important point to keep in mind during this discussion of matching is that we are limiting ourselves to making changes in the value of the load impedance only, and are leaving source impedance strictly alone. Only with this restriction do our rules and definitions apply.

For instance, let's take the circuit of Fig. 2, which consists of a battery, its internal resistance (drawn separately), and a load resistor. If we could vary *both* resistances at will, we would find that the maximum power in the load resistor would be achieved not when both were of equal value, but when the internal resistance was much smaller than the load resistor. With the internal resistance fixed, however, (say at 6Ω) we find that the maximum power is developed with the same value in the load. With a 12V source and a 6Ω load, we get 6W dissipated in the load. Reducing the load resistor to 5Ω makes our current 12/11A and our dissipated power 720/121W (I^2R), or 5.95W. Increasing load resistance to 7Ω makes the current 12/13A, and the power becomes 1008/169 or about 5.98W.

R	I	POWER
5	12/11	$\frac{5 \cdot 12^2}{11^2} = 5.95$
6	12/12	$\frac{6 \cdot 12^2}{12^2} = 6.00$
7	12/13	$\frac{7 \cdot 12^2}{13^2} = 5.98$

Fig. 2. When impedances are purely resistive, maximum power is always taken by load which is neither higher nor lower in resistance than power supply's own internal impedance. If internal impedance is fixed at 6Ω as shown here, then load resistance of 5Ω draws more current, but smaller resistance results in less power being taken. Load resistance of 7Ω draws less current, and again power goes down. Only when source and load impedance are equal does power taken by load reach maximum 6W level.

Before confusion becomes complete, let's review the key points we've encountered. Impedance matching has at least three meanings. The most common is *providing some specified, required value of impedance as a device's load.* The second is identified as maximum-power-transfer matching, and means to make the load impedance equal in resistance to the source impedance, and equal-magnitude-but-opposite-sign in reactance. The third, called image-impedance matching, means making the load impedance the exact duplicate of the source impedance. Finally, in case both source and load impedance are free of reactance and involve only resistance, the maximum-power-transfer and the image-impedance matches turn out to be identical to each other.

Before we move on to see how such matching is performed, let's look at some examples to illustrate the various meanings.

One ready example not directly connected with ham radio is the matching between amplifier and loudspeaker in a top-quality hi-fi or stereo system. Most of the tube-type amplifiers are rated to operate into a 16Ω load impedance, although they likely have output connectors marked as 8Ω and 4Ω. The speakers, similarly, are rated at either 4, 8, or 16 ohms. The speaker to the amplifier, we simply connect the speaker to the amplifier terminals which are marked with the same impedance value.

In actual fact, the "impedance" rating is somewhat inaccurate since it includes neither reactance nor phase angle, which we saw a while back is required for accurate specification of impedance. In addition, the true impedance of any speaker varies widely over its operating frequency range, and few if any come anywhere within 20% of their rated impedance at more than three or four spot frequencies.

These points make very little difference, because the actual source impedance presented by the amplifier is almost always far smaller than the rated impedance.

What does make all the difference is that the 4, 8, and 16Ω ratings provide a means for specifying the "black-box" characteristics of both amplifier and speaker. Any amplifier with a 16Ω output terminal can be expected to operate with any speaker rated at 16 ohms impedance, regardless of actual impedance characteristics of either amplifier or speaker.

This, then, is an example of the first meaning of impedance matching; we provide a specified, required load impedance value.

Another example is offered by the 117V power outlets in almost every home. While we usually talk about our electric power in terms of voltage or sometimes wattage (a 100W bulb, for example) this still is a close relative of the first kind of impedance matching. We know that any device rated to operate on 117V, 60Hz power will operate when plugged into a normal outlet; we don't have to specify all the electrical charateristics of the power company's generators and transformers on each electric appliance.

Maximum-power-transfer matching is the usual rule for connecting transmission lines and antennas to radio transmitters. The objective is to radiate as much of the transmitter's output as possible, which is just another way of saying "maximum" power. Antenna and feedline matching is often thought of as though it were done on an image-impedance basis – but when the normal practice of tuning the feedline to eliminate reactance is looked at in a slightly unusual light, it can be seen as a way to provide reactance of equal value but opposite sign and so to achieve max-power matching.

In fact, the whole art of matching transmission lines to antennas and transmitters *is* the art of maximum-power-transfer matching, and we will get into this type of impedance matching much more deeply when we get around to looking at antenna theory.

Despite the misconceptions held by most of us as to what an impedance match consists of –,which would indicate that the only true match was an image-impedance match – examples of true image-impedance matching are difficult to find.

Possibly the closest to this situation is the audio practice of matching all long lines to an arbitrary 600Ω impedance, initiated originally by telephone companies in order to provide a "standard" matching condition and adopted by all others who had to deal with telephone lines. Since most audio equipment rated at 600Ω actually has a slight bit of inductive reactance as well (associated with the matching transformers almost universally used to reach the 600Ω level), this type of matching meets the image-impedance definition.

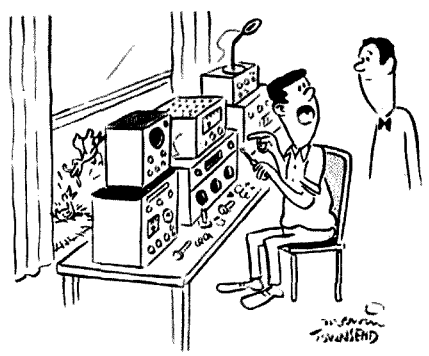
Now that we've defined impedance matching in its three variants, let's see how it is accomplished:

The most common method of matching impedances is by the use of a transformer. A transformer consists essentially of two inductors coupled to each other so closely that the magnetic with the magnetic field

ARRL DIRECTORSHIPS

The ARRL elections for directors are about ready to close. Don't let the do-nothings get into office again. Make sure the fellow you vote for is devoted more to amateur radio than he is to the League.

FM'ers in the Southwest Division should be advised that John Griggs has done more to boost FM than any other director anywhere. His performance record in office has been satisfactory, the Southern California boys say, and he is responsive to the needs of amateur radio. Most important, he does not appear to be glory-hungry and he listens to the advice offered by his informed associates.



Since time is so short, there has been no opportunity to evaluate all nominees, but poor "performance in office" is cause enough to reject some of the directors who are seeking reelection. Here are a few of the directors who, in the opinion of some of our readers, are hurting amateur radio by their past performance (or lack of it):

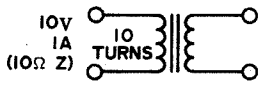
"I can't seem to locate that peeping sound."

associated with one of them coincides with the magnetic field of the other. When this is the case, a change in current flow through the first inductor causes variations in the common magnetic field, and these variations in the magnetic field induce current flow in the second inductor. Energy is thus transferred or coupled from one circuit to another with no conductive connections; the common magnetic field does the "connecting," replacing the usual wires. Because a change in the magnetic field is necessary for a transformer to operate, the device is effective only with ac. In a dc circuit, a transformer produces one spike of energy in the output when power is applied and the initial current flow begins, and another spike of opposite polarity when power is removed and current flow begins, and another spike of opposite polarity when power is removed and current flow ceases. In between, nothing happens.



Because the transformer does its job by means of the magnetic coupling between two inductors, it introduces a 90-degree phase shift just as would any other inductor. This is usually ignored.

The transformer's ability to serve as an impedance-matching device depends upon the relationships that exist between current intensity, magnetic field strength, and inductance. We've gone through most of the necessary background when we met inductance to begin with. All we need to point out now is that the strength of the magentic field depends upon the number of turns in the inductor, and similarly the intensity of the induced current also depends upon the number of turns, but in opposite ways.

This means that if one of our inductors contained 10 turns it might develop a magnetic field strength of 10 units with one ampere of current. If the other inductor also contained 10 turns, the resulting magnetic field would induce an identical current intensity (assuming that the coupling is perfect and none of the magnetic energy goes to waste). However, if the second inductor contained 20 turns, the current intensity would be only half an ampere because each unit of magnetic field

strength would have to release its energy to twice as much wire and could only give each turn half as much. And if the second inductor were only five turns, then each unit of magnetic field would affect half as many turns, and so would produce twice the current intensity.

Keeping in mind that we're talking about a "perfect" transformer which loses no energy, all of the energy put into the circuit must appear in the output. If the input energy comes out to be a 10W rate, with 1A flowing, it must be at 10V. We get that same 10W out; if current intensity is only 0.5A, the voltage must have been increased to 20V, and if the current intensity is raised to 2A the voltage must have been reduced to only 5V. Figure 3 summarizes these points.

TURNS	I	E	Z
5	2	5	2.5
10	1	10	10
20	1/2	20	40

Fig. 3. Transformer operates by converting current changes in primary winding into changing magnetic field, and reconverting magnetic field changes which result into new current changes in secondary. Voltage, current, and impedance levels are all transformed from original values to new values which depend on the ratio of the numbers of turns in each winding. Chart shows results for three sizes of secondary winding, if primary is fixed at 10 turns, and takes 10W (1A) from 10V source for impedance level of 10Ω.

That's where the name "transformer" originally came from, because this device transforms voltage or current levels either up or down. It does so, however, without adding any energy. Any real transformer, naturally, must be less than perfect, so it will really lose a little of the input energy.

The real functions of a transformer are easier to see, though, if we think of the same thing. In an ac circuit, we use impedance rather than resistance in the Ohm's Law equation. Our sample transformer which accepted 1A of current from a 10V source represented a 10Ω resistive impedance (10V/1A). When it stepped voltage up to 20V and current down to 0.5A, it transformed the impedance level from 10Ω to 20/0.5 or 40Ω. When it stepped voltage down to 5V and current up to 2A, the impedance went from 10Ω to 5/2 or 2.5Ω.

By adjusting the ratio of the number of turns on the input inductor (usually called the primary winding) to those on the output inductor (secondary winding), any desired ratio of impedance transformation can be obtained. The rule is simple; the ratio of impedances is equal to the *square* of the number of turns in a transformer with tight coupling between winding. The square gets into the act because the ratio of voltages is the same as that of the number of turns, while the ratio of currents is the inverse of the number of turns (because current goes up as turns ratio goes down). Impedance ratio equals the voltage ratio divided by the current ratio, and dividing any number by its inverse is the same thing as squaring the number.

Normally, this arithmetic isn't necessary; the transformer manufacturers have already done it for you and any transformer you buy which is intended for impedance matching is rated by its intended impedances. You will find, though, that most are rated for specific input and output impedance values rather than by ratio. They will provide the ratio, however, in every case.

That is, if you need a transformer to match 6 kΩ to 8Ω, and have one which is rated at 3 kΩ primary, 4Ω secondary, you have the one you need. 6000:8 is the same ratio as 3000:4 or 1500:2, or 750:1.

You can also use power transformers, in a pinch, to match impedances if the ratios are close enough. To do this, convert the input and output voltage ratings into a voltage ratio by dividing the larger voltage by the smaller. For instance, a 120V to 6.3V filament transformer has a voltage ratio of 120/6.3 or almost 20:1. Convert this to an impedance ratio by squaring it; we get approximately 400:1, which is close enough. This would match an 8Ω loudspeaker to a 3 kΩ power amplifier output, or 16Ω to 6 kΩ.

Most transformers you can buy are for use at audio or i-f frequencies, but the

transformer principle is also used in rf circuits. Almost all transmitters use transformer coupling between stages, although not by that name.

The transformer is not the only method of matching impedances, but it's probably the most efficient.

Special amplifier circuits, known as "cathode followers" and "anode followers" when vacuum tubes are used and as "emitter followers" or "common-collector circuits" when transistors are employed, also have an ability to transform impedances, but they do so in a much different fashion. In general, transformer matching cannot always be replaced by special amplifiers, although in special cases they can.

One method of impedance matching sometimes used in audio and communications work is by means of matching "pads," which are circuits of series and parallel resistors so arranged that from one side of the circuit it presents one impedance level, and from the other side, another. The simplest matching pad is the resistive voltage divider, which is merely two resistors in series.

The advantage offered by the matching pad as compared to the transformer is that it is much less expensive – but this is offset in most cases by the fact that a matching pad must waste more than half the energy present in the circuit, and the greater the ratio of impedances to be matched the greater the loss in a matching pad. For an 8:1 impedance ratio, the loss is 35 dB – more than 99.9% of the energy lost! The transformer, while it costs more, rarely has more than 1 dB loss.

What is a Filter?

In any electrical circuit, it's sometimes necessary to select specific kinds of signals and separate them from other kinds also present in the circuit. In general, the devices or circuits used to do this job are known as filters. The name comes from the similarity to a physical filter such as the oil filter in an automobile, which separates grit from the oil.

Any device or circuit which separates signals into two or more groups can be rightfully called a filter. Since a filter is anything which does this job, we must have various categories into which to classify filters.

One major classification method is to divide filters into *active* and *passive* filters. Active filters are circuits which make use of amplifiers as a part of the filter itself. They are relatively recent developments and are seldom encountered in ham radio; about the only devices used by amateurs which may be termed active filters are the Q-multiplier and the select-o-ject circuit. For now, we won't pursue active filters further.

Passive filters are circuits which do not contain amplifiers within the filter circuit. Most filters are of the passive sort, and throughout this installment when we use the term filter we will be speaking of the passive type.

Another way to classify filters is by the type of action they perform (Fig. 4). All

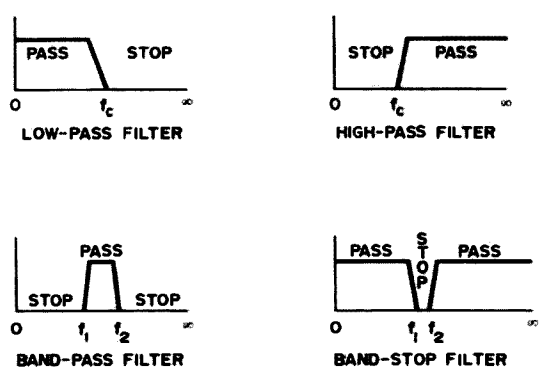


Fig. 4. Idealized frequency-response charts illustrate principal characteristics of low-pass, high-pass, band-pass, and band-stop filters. Each separates applied input signals into groups which are either passed or stopped. Frequencies which mark boundaries between these bands are known as cutoff frequencies.

filters separate signals into two or more groups, but they do so in different manners. This classification scheme puts any filter into one of four groups – low-pass, high-pass, band-pass, and band-stop.

The separation action of a filter can be described as letting one group of signals (passband) go through, and blocking all

other signals (rejection band or stop band). The frequencies at which the passband and the rejection band meet are known as cutoff frequencies.

A low-pass filter passes all signals below its cutoff frequency and rejects those above; that is, its passband goes from 0 Hz up to cutoff, and its stop band goes from cutoff on to infinitely high frequency.

A high-pass filter rejects all signals below cutoff, and passes all those above. Its stop band corresponds to the low-pass unit's passband, and vice versa.

A band-pass filter has one passband and two stop bands. The first stop band runs from zero frequency up to the lower cutoff frequency, and the second stop band runs from the upper cutoff frequency to infinity. The passband is the region between lower and upper cutoff frequencies. A resonant circuit, by virtue of its selectivity, is a band-pass filter.

A band-stop filter is the opposite of a band-pass filter; it has two passbands and one stop band, and passes all signals except those between its lower and upper cutoff frequency.

In practice, the band-stop filter is rarely encountered. Power supply filters are excellent examples of low-pass filters with cutoff frequency lower than the ac power line frequency, so as to leave only dc in the output. Tuned circuits are examples of band-pass filters. The kind of TVI filter which is connected to the TV receiver (rather than to the transmitter) is a high-pass filter.

Performance is not the only classification criterion, however. Filters may also be grouped according to the techniques used in their design. This involves two major techniques, each of which has a number of subcategories.

The major design techniques are known as "image impedance design" and "modern network theory" methods. Most filters in the past 50 years have been designed using image impedance methods, although this technique requires the use of physically impossible components and so cannot produce accurate results. Within the last decade or so, the modern network theory method has been brought to prominence to provide more accurate filter action.

Filters designed by image impedance techniques fall into two subcategories, known as *constant-k* and *m-derived*. Both these labels are just names, and bear no relation to the performance characteristics of the filter. The *k* and *m* refer to mathematical variables used in the design equations.

Filters designed by modern network theory methods bear names associated with the mathematicians who studied the various types of equations involved in the theory. The most widely known of these filter types is the *Tchebychev*. Less well known is the *Butterworth* design.

Classification by design method is not rigid, because many of the design techniques overlap. It's quite possible to encounter an m-derived Tchebychev filter, and the entire image-impedance technique is actually a special case of the Butterworth design area, although it's not usually so labeled.

To complicate the question a little more, filters always include both series and parallel components, at least one of which (and often both) is reactive. This means that the most primitive building block possible in a filter is the combination of one series element and one parallel element. Such a circuit (Fig. 5) is known as a half-section.

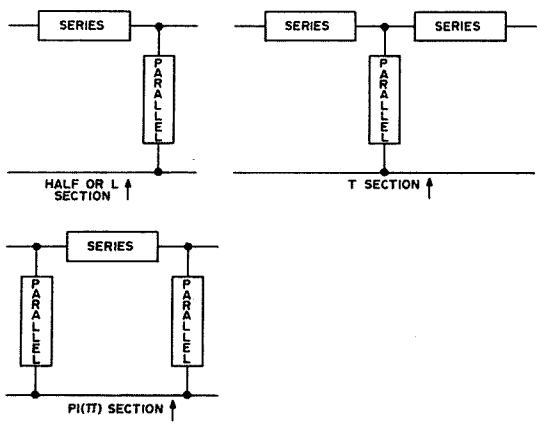

Fig. 5. Different arrangements of components in filter circuits bear names suggested by resemblances to various letters of alphabet. Pi-section resembles no letter in our own alphabet, but is dead ringer for π of Greek alphabet. Elements represented by boxes here may be resistors, capacitors, inductors, or combinations of any or all of these.

Half-sections can be connected together so that the two series elements meet, or so that the parallel elements meet. In either case, the two elements which meet can be combined into a single element; the resulting three-element circuit is known as a section. If it has two series elements but only one in parallel, it's called a T-section (from its resemblance to the letter). If there's only one series element and two in parallel, it's a pi section, from the resemblance to the Greek letter π. And if we don't combine at all but use only a half-section, it's sometimes called an L-section.

That's not all the possibilities, but we have enough on hand for the moment.

The functional description – high-pass, low-pass, band-pass – is most generally used, unless it's necessary to be more explicit about the particular filter circuit involved. Even then, the functional description is usually retained, and the added classification simply tacked onto it, to give us a "low-pass constant-k filter using π-sections" or a "high-pass m-derived filter using T-sections."

A final classification – "balanced" and "unbalanced" – must wait until we examine the details of filter operation for its discussion. Let's move right on.

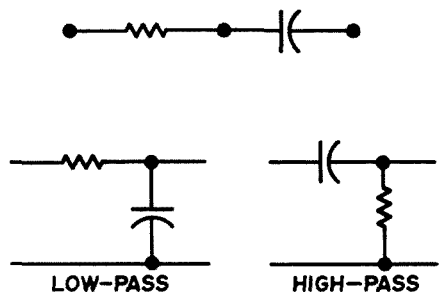

Fig. 6. Simplest filter circuit consists of one resistor and one capacitor in series, as shown at top. This forms an RC L-section, which may be used for either low-pass or high-pass purposes as shown in the two lower schematics. Method by which filter operates is explained in text; all filters work on this basic principle, but more complicated circuits modify it in various ways because they contain not just one but several reactances, each of which behaves differently.

How Do Filters Operate?

We have just seen that filters act to separate signals into groups by permitting signals in the passband to go through, and rejecting signals in the stop band(s). How is this accomplished?

The clue is hidden in our statement that every half-section of any filter contains at least one and often two reactances. A reactance is frequency-sensitive. That is, its characteristics depend upon signal frequency. By combining reactances of proper types and values, we can get almost any kind of filtering action we may desire.

To show how this works, let's begin with the simplest possible filter arrangement (Fig. 6) containing only a single half-section and a single reactance. We already looked at this circuit, but not in this context. It contains a resistor and a capacitor, with input applied across both and output taken across only one.

This circuit can act as either a low-pass filter or as a high-pass unit, depending upon which element the output signal is taken across. To see how this works, let's assume that the resistor's value is 1 kΩ, and that the capacitor's reactance is 1 kΩ at a frequency of 1 kHz.

For an input signal of 10V at 1 kHz, then, since resistance and reactance are equal at this frequency, we will get the same voltage across either the resistance or the reactance. Because of phase shifting, we will actually find 7V across either; we went into the reasons for this before. With 10V input and 7V output, we have 3 dB loss.

If signal frequency goes up to 2 kHz, the resistance will not change but the reactance will decrease to 500Ω. We now have less voltage developed across the capacitor than across the resistor. As signal frequency is increased still more, the reactance keeps going down; when we reach a signal frequency of 10 kHz, the reactance is only 100Ω, and at 100 kHz the reactance is down to 100Ω. Resistance remains unchanged, so that the voltage division between resistor and capacitor reduces capacitor voltage and leaves most of the voltage across the resistor.

If our output voltage is taken across the capacitor, we have a low-pass filter. As signal frequency goes up, output voltage goes down. If, on the other hand, we take the output from the resistor, our filter is a high-pass unit, as output voltage increases with frequency.

At dc or "zero frequency," all the input voltage appears across the capacitor. At the frequency at which resistance and reactance are equal, 70% of the voltage (half the power) appears across the capacitor. At infinite frequency (a purely theoretical idea, granted) no voltage at all appears across the capacitor. In between, whenever signal frequency is doubled, the output voltage drops to half what it was before, because the reactance drops to half its previous value.

This somewhat idealized description leads to the idea of a "6 dB per octave" cutoff rate. Cutting voltage in half is introducing a 6 dB loss, and doubling the frequency is equal to going up an octave in the musical scale. The theoretical limit of the effect of a single reactance is 6 dB per octave.

An actual RC filter like the one we've been examining does not reach this rate in practice. Its cutoff frequency is defined as being the frequency at which X and R are equal (1000 Hz in our example) and in that region the slope is only 3 dB per octave.

We can improve its performance in several ways. One is to cascade additional half-sections. This modifies its action in many ways, since the first reactance now has another half-section in parallel with it and no longer behaves as a pure reactance. Another (Fig. 7) is to replace the resistor

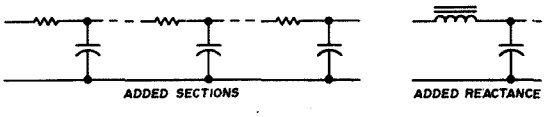

Fig. 7. When performance of simple filter of Fig. 6 is not adequate, either or both of two routes may be taken to improve it. Sections may be added (left) or additional reactances may be included (right). Usual filters encountered in practice do both; design technique is rather complicated but results justify it.

with an inductor, thus putting two reactances in rather than one.

When we do either of these things, we immediately find ourselves involved in the intricacies of filter design. With both inductive and capacitive reactance in the circuit, we have the certainty of resonance at *some* frequency, and this may or may not be good for our purposes. This is not the place to delve deeply into filter design theory; all we can do is skim the surface enough so that we are able to identify the various parts of any kind of filter.

The constant-k filter design procedure amounts to a method for replacing the resistor with an inductor, together with adding additional half-sections, to produce a filter with the desired cutoff frequency and cutoff rate. The resulting filter's input and output impedances will vary in a definite manner which the designer cannot control, so that this type of filter can be used only when its impedance characteristics are satisfactory for the purpose. A typical power-supply filter amounts to a constant-k low-pass filter; the "choke-input" filter uses a T-section followed by an L-section (with two of the three inductors combined into one so that it appears to be two L-sections), and the "capacitor-input" filter is a π-section standing alone.

The m-derived filter design procedure offers the designer another level of control. He can achieve the cutoff frequency and rate desired, just as in the constant-k procedure, and in addition he has the option of controlling either the impedances or the attenuation characteristics (but not both). To do this, a part of the circuit resulting from the constant-k design is converted into a resonant circuit. The ratio between cutoff frequency and the resonant frequency of this converted portion yields the variable named m, which gives the procedure its label.

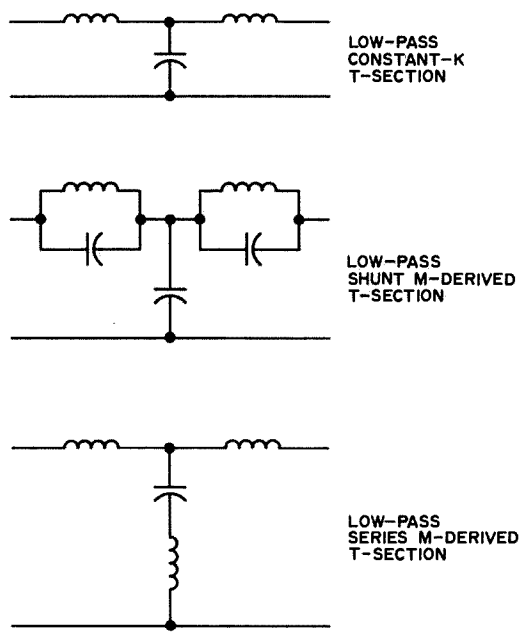
The distinction between a constant-k filter and an m-derived filter (Fig. 8) is simply the presence of a resonant circuit where one would expect to find only a single reactance. If such a circuit is present, the filter is m-derived.

Filters designed according to modern network theory techniques may look the same as either type of image-impedance circuit. In these designs, the engineer trades off the ability to control certain characteristics in order to gain control over others. The most popular Tchebychev designs, for example, permit some degree of ripple (uneven response) in the passband to achieve a cutoff rate greater than the theoretical 6 dB/octave/reactance limit for image-impedance designs.

These trades are made by designing each separate section of the filter for a different cutoff frequency; the complex math involved in the design procedure specifies the particular cutoff frequencies to be used.

Regardless of the design procedure, a filter may be built to operate in either a balanced or an unbalanced condition. These terms are not limited to filters – they apply to all signal transmission circuits, and affect filters only because filters are used in signal circuits.

The most conventional practice for any kind of signal transmission is to ground one side of the transmission path, and then work a hot line against ground throughout



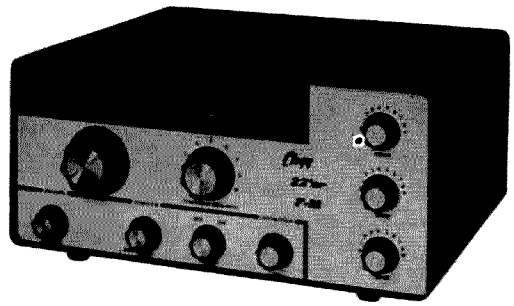


Fig. 8. Differences between "constant-k" and "m-derived" filters are apparent when the schematic diagrams are examined. Any "m-derived" filter contains resonant circuits replacing simple reactances. "Series" and "shunt" portions of names refer to type of resonant circuit, either series-resonant or parallel (shunt).

the resulting system. This is unbalanced operation.

It's equally feasible to keep both sides of the path separate from ground. If the circuit is arranged so that both sides of the path are separate from ground, but so that one is always above ground level when the other is below and vice versa, the circuit is said to be balanced. A push-pull amplifier is a good example of a "balanced" circuit. So is the industrial circuit known as a "differential" amplifier, in which the signal is the *difference* between the individual signals on each input line.

In an unbalanced circuit, any accidental stray coupling between circuits cannot be readily corrected since there is no way to distinguish between desired and undesired signals. Most of the undesired signals are inherently unbalanced in nature.

The balanced circuit permits such a distinction, because it is possible to reject any unbalanced signals appearing in a balanced path. Commercial telephone circuits are all balanced for precisely this reason; it permits the reduction of crosstalk to acceptable levels.

A filter for use in an unbalanced line must be itself unbalanced. The sample circuits we've been examining are all unbalanced; the series element appears in only one side of the filter, and the input and output terminals have a common or ground reference.

To convert such a circuit to a balanced filter for use in a balanced line, the series elements are divided between the two signal paths (Fig. 9). Then half of each series element appears in each side of the line. The total series impedance is unaffected by this change, but there is no longer a common terminal between input and output.

What Is Amplification?

In all the circuits we've looked at so far, we have had only one generator or power source and all the rest of the circuit has been composed of passive components that dissipate energy or convert it from one

form to another, but which have not added any additional energy.

In practice, radio deals with extremely small amounts of energy. It's necessary to boost the energy levels while retaining the

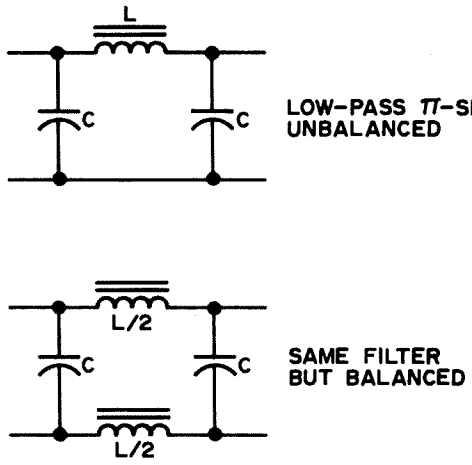

Fig. 9. Most conventional circuits are unbalanced in nature, as at top, with both input and output circuits sharing a single common ground line. If balanced circuit (bottom) is in use, input and output circuits have no terminals in common. Any design may be converted from unbalanced to balanced operation by splitting series elements between the two signal lines.

major characteristics of the original energy. Any device which does this job is known as an amplifier.

This definition of "amplifier" is intended to make it plain that every amplifier provides a source of new or added energy to a circuit. In addition, it must control this added energy in such a way as to make it conform to the desired (or major) characteristics of the original energy in every way except strength.

An amplifier, then, is a device for adding energy while controlling its characteristics – and amplification is the process of doing this.

One way of adding energy is to introduce a generator into the circuit. Another way is to add a battery. Unfortunately, while the energy from a battery is plentiful enough, it's difficult to control.

However, we have been making much use of the voltage-division capability of series circuits composed of resistors. If we have two resistors in series with our battery, one of them fixed in value and the other variable, we can control the added energy by varying the resistance of the variable resistor.

We now have the basics of a rudimentary amplifier – a source of energy to be added, and a means for controlling the energy. It may come as no surprise to find that almost all practical amplifiers boil down to this simple basis – a battery and a variable resistor. (See Fig. 10.)

The variable resistor, though, seldom looks much like what you would expect. Conventional variable resistors achieve their variations by mechanical means, and cannot exert control rapidly enough to follow all the gyrations of an ac signal. The variable resistors we find in practical amplifiers to control the added energy achieve their variations by *electronic* means rather than mechanical. We call them vacuum tubes and transistors.

We'll examine the actual methods by which vacuum tubes and transistors achieve variable resistance later; each does it differently. The important point at this stage is that so far as the electrical circuit itself is concerned, they do act as variable resistances, whose resistance depends in some way upon the input signal. The British term for the vacuum tube – valve – is highly descriptive of the function. A small input signal controls the resistance which the tube offers in the energy-adding circuit, and thus produces an output signal which matches the input in every desired way.

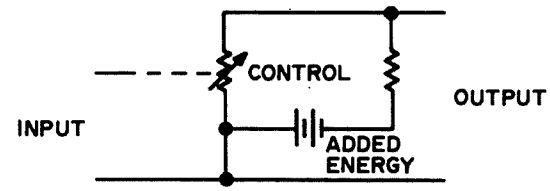

Fig. 10. Basic amplifier circuit consists of source of added energy and variable resistances controlled by input signal which together permit input signal to control amount of energy added. Schematic diagram shows the principle involved, but no real amplifier looks much like this. Control function is usually provided by either transistor or vacuum tube, which is acting as electronically variable resistance.

By proper circuit design, we can make the output signal's characteristics match all of those of the input signal, or we can select only a few features of the input signal and eliminate the rest from the output. The ability to do this makes it possible for us to modify signals in just about any way we like – for instance, we can preserve the frequency characteristic while eliminating any changes in strength, and this is what makes FM so much more free of atmospheric noise than AM. We can preserve the variations in strength while changing the frequency, and this makes today's sensitive receivers possible by permitting the "superhet" receiver design. Or we can preserve all the original characteristics, boosting only the strength, and we have full fidelity sound systems. All of this depends upon the control inherent in the amplification process.

How Do Transistors Amplify?

At the moment, we're interested primarily in transistors and how they amplify. We'll wait until later to approach vacuum tubes, which operate rather differently although they do the same basic things.

The name transistor itself comes from a blend of *transfer* and *resistor*; before the transistor, few persons thought of amplification in terms of variable resistances and steady energy sources. Instead, they thought in terms of imaginary "generators" of ac inside the amplifier – and many of today's engineering textbooks adhere to this concept.

But the transistor has nothing in it which even remotely resembles a generator, and it does its job precisely by controlling series resistance, so the "steady energy source/variable resistance control" is a direct picture of how transistors operate.

A transistor consists of three distinct regions of semiconductor material joined into a single crystal. It's something like a sandwich, except that the "junction" regions which separate the different types of material are actually part of a single continuous structure. The two outer regions are of the same type of material, and the inner part is of the opposite type.

CONNECTICUT'S OLDEST HAM STORE

The semiconductor materials used are primarily either silicon or germanium. Both these are metallic elements, and both of them, in an absolutely pure state, are rather good insulators. If very small amounts of specific kinds of impurities are added, however, they become rather good conductors. One kind of impurity (donor) puts an excess of electrons into the crystal structure, while the other kind (acceptor) doesn't have quite enough electrons and so produces "holes" where electrons can rest but cannot quite fit permanently.

Semiconductor material containing donor impurities is called N-type material, and that containing acceptors is known as P-type.

A transistor, then, consists of either two regions of P-type material separated by a region of N-type, or of two regions of N-type separated by P-type. The first is called PNP, and the second NPN. Since they are mirror images of each other, we'll look only at the operation of an NPN transistor. To apply this to a PNP unit, simply reverse all the polarities involved.

Before we get inside a transistor, though, let's see what happens at a single junction (Fig. 11). Such a junction, P-type on one side and N-type on the other, is widely used; we call it a diode.

If we connect a diode into a dc circuit with the P-type material connected to the positive side of the power source and the

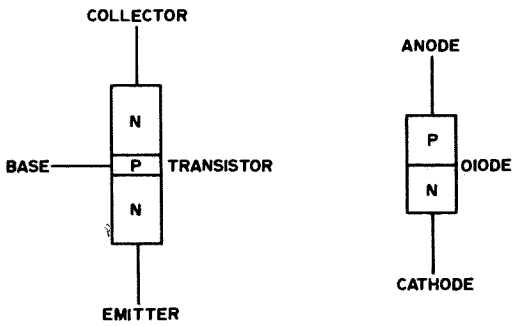

Fig. 11. Transistors and diodes consist of slabs of semiconductor material formed into a single structure. Differences in atomic characteristics between crystal in N-type region and that in P-type region provide required control actions.

N-type to the negative side, then we find that the excess of electrons at the negative side of the power source meets a similar excess of electrons in the N-type material, and the resulting repulsion between electrons must be overcome before any current can flow. The resistance is rather high.

If we reverse polarity of the connections, then the excess of electrons at the negative side of the power source find room to move into the "holes" of the P-type material, displacing the excess electrons from the N-type material across the junction and sending them on to fill the shortage of electrons at the positive side of the power source. Current flows readily. The resistance is low.

The diode, then, has low resistance for current flow in one direction, and high resistance to current flow of the opposite polarity.

When we add a second junction to put the third region into our device and change it from a diode into a transistor, each junction still retains this one-way characteristic. However, events at the two separate junctions interact with each other.

We call one of the outer regions the emitter, the other outer region the collector, and the inner region the base. The junctions are known as the base–emitter junction, and the base–collector junction. In practice, we apply the input signal into a circuit which includes the base–emitter junction, and it controls the resistance of the base–collector junction. Fig. 12 shows the arrangement.

The interaction between junctions is such that the base–emitter junction must be operating in its low-resistance condition (forward biased), and the base–collector junction in its high-resistance condition (reverse biased) for the control to occur.

In essence, what goes on is this: Some of the electrons moving in the base region as a part of the base–emitter current escape from the base by way of the base–collector junction, instead of through the base–emitter junction. In the base–collector junction, these "injected" electrons are going the wrong way on a one-way street. That is, they are going in the opposite direction, and so tend to *reduce* the amount of reverse bias maintained on the junction. This reduction of reverse bias amounts to a decrease of resistance.

If only a small portion of the electrons injected into the base–emitter circuit escaped into the collector circuit, the effects would be correspondingly small. However, the geometry of the regions is such that *most* of the current in the emitter region goes on through the base into the collector. Only a small fraction of

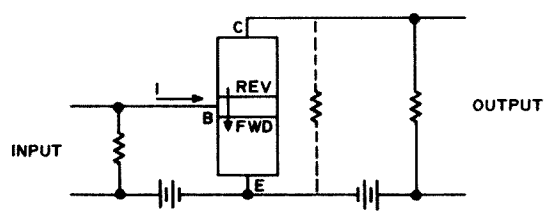

Fig. 12. Current flow through base–emitter circuit controls that in collector–base circuit by interaction in base region. Shown here is common–emitter circuit arrangement.

the emitter current appears in the base circuit. The result is that the effects are correspondingly large. A current of only a few millionths of an ampere in the base–emitter circuit controls currents thousands of times larger in the collector circuit, and we have amplification.

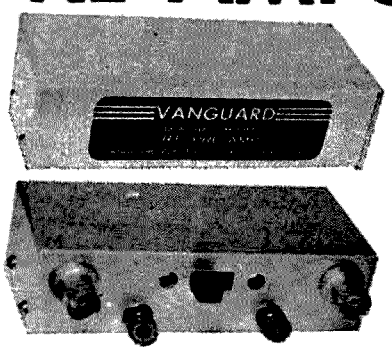
Something similar goes on in tubes, but the control action is different. In a tube, electrons boil off of the cathode and travel to the plate, passing the grid in the process. The voltage level on the grid controls the number of electrons which get through, and so controls the plate current.

That is, the cathode in a tube corresponds to the emitter of a transistor, the grid corresponds to the base, and the collector to the plate.

The major factor used to rate transistors for "gain" currently is a ratio known as *beta*. A transistor's beta is the ratio between base current and collector current; if a specific transistor will permit a collector current of 50 mA to flow with a base current of 1 mA, it has a beta of 50/1 or 50.

The beta of an individual transistor depends upon many factors. The voltage applied to the collector is one such factor. Another is operating temperature (the hotter the unit, the less control the base current has over collector current). In general, however, beta depends primarily upon the internal design of the transistor, and remains relatively constant. Modern transistors range in beta from around 10 to over 500.

Neither transistors nor tubes are all-purpose amplifiers. Each has its own area of application, but the two areas overlap rather widely.



Transistors are used in almost all commercial audio amplifiers; they are also used as rf amplifiers at lower power levels. (High power, high frequency transistors exist, but they are expensive.)

This examination of transistor action and how it compares with that of tubes has of necessity been kept brief; you can find more details in our previous study courses for the Advanced and the Extra license examinations. While we have included here enough to meet the current General study list, it's likely that as time passes the General examination also will concentrate more and more upon transistors and less and less on vacuum tubes. When that happens, the additional information will probably be necessary – so if you can, do some additional studying about transistors. It may not be needed to get your ticket, but it will definitely help you understand the equipment you'll be using afterwards!

DUAL GATE MOSFET

PRE-AMPS

to 175 MHz. $21.95 ppd.
to 300 MHz. $25.95 ppd.

NEW FOR 1970!
The above models now have rf gain control.

For 300 to 470 MHz
See Model 202 in our catalog.

- Available from 5 MHz. to 450 MHz. Bandwidth is approximately 3% of frequency.
- Voltage gain 30 to 40 DB depending on frequency.
- Two Dual Gate MOSFET amplifier stages with each having a tuned input and tuned output. Each Dual Gate MOSFET is actually an integrated cascode circuit thus giving you 2 cascode circuits equivalent to 4 triodes.
- Exceptionally low noise (2.5 DB at 175MHz.), greatly reduced cross modulation and 10 times the dynamic range (signal handling capability) of the best bi-polar transistors. Also superior to preamps using junction FETs and Single Gate MOSFETs.
- Internal connections for high impedance AGC or manual gain control if needed.
- Type BNC input and output receptacles for minimum loss at UHF. Standard impedance is 50-75 ohms.
- Carefully tuned at our laboratory with sweep generator and oscilloscope for the best bandpass characteristic.
- Full wave UHF diodes protect input transistor.
- Operates on 6 to 16 volts DC, 5 to 15 Ma.

New York City and State residents add local sales tax.

196-23 Jamaica Ave., Hollis, NY 11423

depend upon it, but who are now unable to make full use of it. It would bring hundreds of thousands of nonhams to a logical "jumping-off" place from which to advance themselves into our ranks, thus promoting a healthy growth for the hobby. This would provide us with a source of raw ham material for many years to come, and we could certainly use more hams, if we are to continue growing. The band which has been proposed is not widely used; consequently, its restructuring would not impose any inordinate hardship on its present users to any great extent.

For these reasons I have come to the conclusion, and I think that many others will too, that this proposal is a good one, and should be adopted in the near future.

Technicians

All right: granted... I have been belaboring the question of Technicians and the proposed allocation of additional frequencies sufficient unto the gravity thereof. And surely, by this time all who have been alerted and alarmed by the sounding of the tocsin will have made their opinions known to the ARRL directors, the FCC, all their friends and colleagues on the air, and anyone else who would listen, and thereby be convinced. I have nothing to add to my fundamental objections. But there are some afterthoughts which, while not speaking directly to the question per se, do bear upon it somewhat.

Any casual survey of the equipment market, both new and used, will disclose that there are very few transmitters or transceivers which are limited to 10 meters alone. Almost every piece of gear on the market includes the other so-called "low bands." Presumably, the Techs, if and when the new allocation becomes a reality, would acquire equipment that would cover not only the segment granted, but all five bands. And on thousands of shack desks, from coast to coast, constituting an ever-present Lorelei, will be sitting, as big as life, a shiny new Whatziss Mark Four, with a couple of hundred watts PEP under the hood, just rarin' to go. Hopefully, most of the fellows will resist the temptation successfully.

Now, I beg of you...don't get me wrong. All you Techs who have absolutely no eyes to exceed your frequency allotment...that is not what this piece is all about. I am not interested in condemning anybody before the fact. I would not dream of indicting anyone of "conspiring to advocate the overthrow of the FCC regulations by force or violence," and so I hope that I will not be smothered in a deluge of angry denunciations, and I trust that 73 will not be on the receiving end of any premature and precipitate cancellations of subscriptions. Please have the patience and forbearance to hear me out before you bite your pipe stem in two.

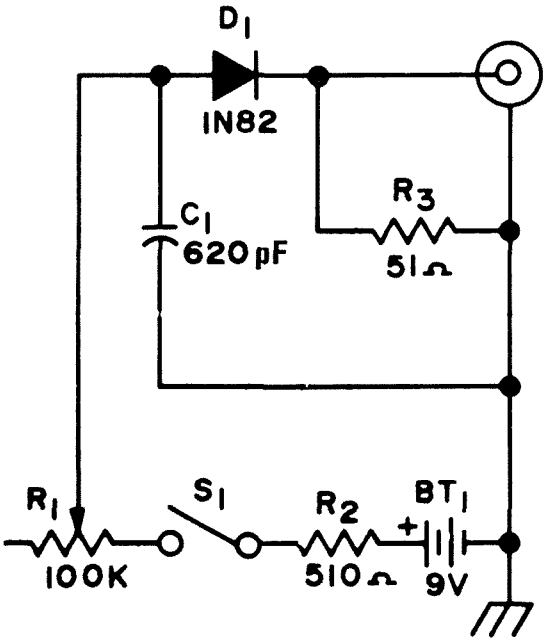
I state now, without any qualifications whatsoever, that I am certain that the overwhelming preponderance of the Tech group, if granted the ten meter segment, will use it precisely in the manner prescribed, and will not make any excursions into portions restricted to them. If there do happen to be any violations, well, they will most probably occur to no greater extent than they do right now, and which originate among all classes from Extra right on down the line. The proportion of law breakers and miscreants holds pretty consistently, no matter what stratum of society (or hamdom). People are people!

Idle curiosity prompts me to ask how the FCC proposes to monitor all the frequencies to see that the occasional "poacher" will be detected. It is surely unrealistic to imagine that an agency with severe shortages of funding and an insufficiency of manpower, which is having trouble policing the presently constituted bands, could suddenly develop the additional capacity to do so under that added workload which is bound to ensue with any change.

I am a devout believer in the honor system. I have seen it work in many fields. Because I hold affirmative views with respect to the inherent honesty and integrity of the individual, I feel confident that we hams are completely capable of policing our own bands for ourselves. And since FCC could not begin to do an adequate job in this connection, it is absolutely imperative that we all feel a sense of urgency toward this problem. It is important that every ham who participates seriously in this hobby makes it his personal business to continue to be vigilant in protecting our bands from deviations from the regulations, by Techs, or *anyone else*.

If we fail to do this, it is possible that the entire image of ham radio will suffer irreparable damage, to the ultimate detriment of our privileges. We must not allow the existence of any condition to which outsiders may point, in their constant efforts to preempt or commandeer our frequencies.

I am not advocating an era of tattletale activity in amateur radio. This would engender an atmosphere of distrust and fear which might be worse than the situation it sought to remedy. But conscientious amateurs are urged to bring their influence to bear upon their associates and friends, in a determined effort to try to prevent wholesale frequency violations. There is sufficient evidence to indicate that only a negligible minority attempts to flout the rules. But we know from recent political history just how much damage a small minority can cause if its activities are not detected and circumvented.



Using Ten for CW

While discussing this matter of the possible change of 10 meter allocations, I have another idea to advance. While it is certain that most of the operators will be utilizing their new segment for phone operation, I should like to remind you and emphasize that operations will not be limited to this mode. The proposal calls for "...voice (or other) emission." There is a golden opportunity here, which for the first time makes it possible for Techs to obtain actual on-the-air experience toward genuine upgrading. There has been no marked attraction for Techs in the practice of MCW on 2 and 6 meters. This poor substitute for CW never approached a status of universal acceptance among them. And this deficiency of means is one of the important reasons why Techs have always had trouble with the code. Now, however, there will be a very convenient avenue through which this discriminatory deficiency may be offset...through which the obstacle may be attacked and overcome. It is to be hoped that many Techs, not content merely with the gain of a small phone segment,

A $1.40 NOISE GENERATOR

There are probably many hams who have at one time or another built a receiver or converter. And probably many of these devices have a less-than-enviable noise figure. With a noise generator, one can work on reducing inherent noise. The noise generator described here is not the best that can be built, but it is probably the least costly thing around in these days of inflation.

The components for this device cost about $1.40. (I scrounged the hardware.) The diode is a 1N82, although almost any UHF or microwave diode could be used.

The 51Ω resistor is approximately equal to the receiver input impedance. It will take about 10 minutes to wire this up. Have fun with the noise!

Stephan Goldstein ■

Leaky Lines *(cont. from p. 96)*

will rise to the challenge, at last, and use the band for CW, in order, finally, to go for the General ticket, and negotiate the exam successfully.

If you agree with this premise, and I hardly see how you can fail to, why not devote a portion of your schedule to regular operation on the segment, for the purpose of assisting Techs in their quest for CW proficience. We can be of great help if we extend the same traditional cooperation we have always given to the Novices on their CW segments.

If we fail in this we may foster twin evils. First: we might simply isolate the Techs into just one more "solitary confinement" situation. Second: we will be neglecting an opportunity to promote the growth of amateur radio through advancement. Let's make sure that not a single Technician who expresses a desire to build his speed and CW savvy fails to find a willing hand among us.

This is a two-way street. We can learn much more from some of the Techs than many of us are willing to admit. They have become specialists and experts in the fields of VHF, ATV, RTTY, FM, and UHF, and remote control. Their participation in the fields of amateur satellites and moonbounce are worthy of recognition and praise. The percentage of Technicians who design and build their own gear is far larger than anything we could match.

The anticipated revision of the amateur spectrum, while it does incorporate some dangers and disadvantages about which I have previously written, possesses some very positive values also. It will present an opportunity for vital interchange and meaningful development in ham radio. Ideally, we will make the most of this chance.

73. . .K2AGZ■

Mr. Virgo Himself *(cont. from p. 14)*

> purchasers. If we had shared this concern we would not have introduced the 1011.
>
> However, despite our conviction that the 1011 is a useful addition to the Swan line, we have decided to defer to our critics and curtail future production of this unit.
>
> Since we have completed one production run of the 1011 we can fill most orders from our dealers promptly, but because of the existing controversy we will not solicit additional orders for this unit.

Well, how about it, fellows? Are we going to leave Swan with this stigma or are we going to outvote the lunatic fringe? Please – for ourselves – write Swan and ask that the Model 1011 not be canceled. That piece of equipment is sound in design and workmanship and it can ideally perform the functions for which it has been engineered. Can we really expect more?

. . . K6MVH ■

(W2NSD cont. from page 10)

This book is so important that I have made arrangements for our Radio Bookshop to handle it. This book should be in every ham's car and handy for every ham's wife too. I just don't see how it is possible to ever lose a traffic ticket case when you have this book in hand.

Do you know what to say and what *not* to say when the traffic cop hands you a ticket? Send $2 today to Radio Bookshop, Peterborough, N. H. 03458 for a copy of this invaluable book. This book can save you future fines, loss of license and a lot of headaches.

King Hussein

As this is being written the Syrians are invading Jordan, the Iraqi troops are poised in Jordan, threatening to support the commandos against the government troops, Amman is in flames and things are generally in an awful mess.

Right in the midst of the furor His Majesty made news all over the world by turning to his ham rig and relaxing with a few contacts. He called Mary WA3HUP, who visited him shortly after I left Amman in May and just before the first serious battle between the government and the commandos in June. He also talked with a few hams in the midwest and talked a bit about the situation in Amman.

CBS news (and others) were on the phone immediately, pressuring Mary to try and contact His Majesty for an interview. Mary, figuring that if the king wanted an interview he would ask for it, declined. They called me to see if I could help them. I agreed to ask if the opportunity arose, but pointed out that I had no intention of putting pressure on him because I was afraid that he might do it for me rather than because he wanted to do it.

It was with relief that I did not hear His Majesty on the bands for the next couple of days. I wanted to help CBS if I could, but I didn't want to create any problems for the king.

There is no way to describe my feelings as I read the papers day by day, following the terrible situation in Jordan. The hotel where I stayed four months ago was being shelled. Commando snipers were shooting at anyone seen peeking out of the windows. Fire and smoke lay in clouds over the city. The commandos held a roadblock at a circle where I had walked and taken pictures a few weeks before. Hummar, the lovely summer palace where His Majesty has his ham station, was shelled by the commandos.

How had the Arab-Israeli situation come to this? Who was to blame? Those of you who have read the Quaker booklet (available from 73 for $1.00) know that there are no angels and no devils, just an unfortunate and really quite logical course of history. A good deal could have been done to keep the situation from getting as bad as it has, to be sure. The booklet points out the best courses of action, all things considered, and with no sides taken.

Naturally I feel empathy for King Hussein and the people who were so nice to me in Jordan. I also feel a great sadness at the loss to the commandos – they feel that they are doing what is best for Palestine and their future. And I respect the Israelis who have done such a tremendous job of building up their little piece of desert into a modern thriving country. I agonize over their impossible decisions as well as I do over the Arabs who demand that the impossible decisions be made. Though I have visited Syria and Iraq and was treated graciously in those countries, it is difficult for me to feel any sympathy for their invasion of Jordan.

With no possible good solution to the worsening situation in sight, we go to press. If any readers do contact His Majesty on the air please give him my best regards and, I hope, the warmest feelings of brotherhood from all amateurs in his time of greatest trial.

Three New Ones

While I am by no means near the top of the DX hierarchy, I have worked enough countries so that a new one is rather hard to come by. Thus it was quite a surprise to me the other day when I managed to snag three new ones all in one evening.

It started off easily. I was heading for the kitchen when the thought struck me that I should check the band, just in case. I didn't know in case of what. The only DX that had been scheduled to show was Frank DL7FT who was reported on his way back to Berlin after an unsuccessful attempt to get on the air from Albania. I tuned twenty meters and there it was – a pileup! I tried to hear who they were calling, but everyone was just giving his own call. Finally one chap let it out of the bag by standing by for Frank. Hmmm, he must have made it after all. The fellows calling him were spread out over the bottom part of the band so I knew Frank must be out of the band. Sure enough, there he was down about 14,192 or so, giving out reports as fast as he could. I checked for a relatively lightly used frequency and gave him a quick call. "The portable one, come again." I'd done it! We exchanged reports and calls and I had a new one.

A couple of days earlier I had gone over to visit editor Ken to try out a beautiful little FM rig that had just arrived from Regency. After giving it a workout we got going on a game of chess and it was 2:30 before I threw the game to Ken in desperation so I could get away. Being a better than average player he probably would have won anyway, so it was no sacrifice. I got back home well ready for bed . . .hmmm, better check the band.

It didn't take long to hear ZK1MA working a list supplied by a W6. I listened for a bit and heard it come to an end. Then fellows started calling in to get on the list for two days later. I entered my call on the list.

Sure enough, right on schedule, not too long after my ZA2RPS contact, list time arrived and I called as my call came up. Nice report from Manihiki and another one in the bag. He gets on

for about an hour a day with his battery powered rig and works a list for the hour. He then spends a day recharging the battery for the next bout. Without the list very few fellows would ever get the country, even so you will probably not be surprised to know that some chaps get on there and intentionally interfere.

After the ZK I tuned up the band and heard a beautiful signal signing off after a short contact. It was too loud to be anyone of great rarity, surely. Wrong. It was VR6TC on Pitcairn Island. When Tom signed and asked for calls the whole band seemed to answer him. I called him a couple times . . .twice more . . .twice more . . .nothing. No answer to anyone. I broke in and talked to a friend for a moment who was coming through on backscatter from New York, then stood by for Tom, just in hopes. And there was Tom coming back to me! It was probably four or five minutes after he had started listening and everyone else had long ago given up and started looking for him up or down the band, figuring that the pileup had discouraged him.

That was a very satisfying evening.

$50 Reward!

Frankly I would like to have some gorgeous girls on the cover of 73 – and it isn't as if we don't have a good supply of 'em in or near the ham ranks. You photographers out there, get your lovely wives, daughters, mistresses, or even neighbors into the shack, up on your tower, or somewhere that will make a good picture for our cover. If the fems have a call, so much the better and extra points from our picture editor. Send in some glossy 8 x 10s. Let your imagination run wild, please. Shoot black and white until our advertising picks up to the point where we can run color covers again.

You can't think of any ideas for pictures? Good grief! Maybe she is helping you put up a beam, a tower, or bringing your dinner to the operating desk while you are in a contest. Perhaps she is just building a kit. Maybe she is operating and you are bringing the supper tray. She might be looking very perplexed at a study manual . . .etc. You can do better than any of those ideas, surely.

Think PR

The Dave Bell Ham's Wide World film is great for us, but it can't carry the entire load of promoting amateur radio forever. Most television stations will show it once and that is it. We do need follow up programs to keep amateur radio in mind as a good thing when those same television viewers start getting interference or see a particularly big beam sprouting in their neighborhood.

The normal ragchew contact does not have much grist for the PR grill, admittedly, but then all of amateur radio is not trivia . . .just most of it.

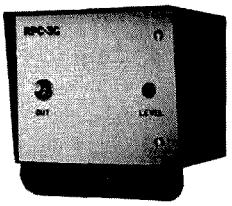
What can you do to help promote amateur radio? You can keep your ears open for PR possibilities. Then, when they occur, you can arrange for the news to get out.

For instance, suppose you have a friend who is talking of a DXpedition to an island somewhere. If he goes to the island, works a thousand or two amateurs and then comes home, the news will hit the ham magazines and that is about all. Big deal! But if he lines up a partner for the trip with a reasonably good movie camera and some experience with it, he can end up with a documentary film of the Dxpedition that will be of interest to dozens or even hundreds of television stations, radio clubs all over the world, and might even pay for itself.

Perhaps you have a friend interested in moonbounce work. Great PR here! Again arrange for a documentary film of the fellow or fellows who set it up, the operation, and pictures of the fellows on the other end of the bounce. You can put in some shots of the moon, the world, and such to explain what is happening. Aerial shots of the layout at VK3ATN would be wonderful for a film on this subject. And shots of the big dish at Arecibo would be interesting too.

Even a short documentary of a local ham building a piece of equipment would fit in the picture. Plan ahead on this and show the unit in its various stages of being built and tested. Other local hams can get in the act, helping with the work or the testing.

Fox hunts can make wonderful movies. Start with a shot of the committee planning the hiding place, then show the rig being hidden. Finally off go the hunters and hidden cameras can record their wanderings. A good director will enact the whole thing rather than doing it from life. This way you can set up for some great shots such as the hunter passing the fox rig and the loop antenna suddenly spinning around. Don't forget close-ups of the gear used for hunting down the fox plus smiling winner pictures.



A repeater group could turn out an interesting film showing their operation, complete with handi-talkies, mobile units, base stations, control units, maps, the works. While this might not be of as much interest to TV stations, it would be wanted by clubs and would fit in a TV series if enough individual amateurs turn out ham films.

Any special club efforts are worth filming, whether it be Field Day or phone patches for a local army hospital.

If film is too much for you to manage, then at least think in terms of slide shows with tape cassettes that can be used by clubs. Most clubs of any size have at least one film nut, complete with, hopefully, a 16 mm camera. Few amateurs have sound film systems yet, but they are coming, either via sound on film or video tape. Even super-8 is better than nothing. Let's get the effort started now and work toward more professional results later.

Lastly: please let me know what you are doing so I can help spread the word to encourage others. And if you need any help in locating TV stations or clubs that would like to see your films just write and then wait for me to eke out an answer. 73. . .Wayne ■

AT LAST
A SPEECH COMPRESSOR THAT
REALLY WORKS

- Low distortion circuit
- 5–10 dB improvement in TALK POWER
- Fully wired & tested not a kit
- Several models to choose from
- Works with phone patch
- Quality construction includes Silicon transistors, FETs, Glass circuit boards
- FULL WARRANTY – ONE YEAR
- Performance second to none
- INTRODUCTORY LOW PRICES – $20.50 – $34.95 (Illinois residents add 5% Sales Tax)

should be boiled in oil ov

That "Fringe"

You fool very few readers with your sly way of trying to subvert the minds of your readers with an attempt to dismiss lightly the role your pal Hussein plays in the Mideast.

His country is used as a haven for terrorists with his permission.

His country is governed by a military dictatorship; he as its head as king.

His country is allied to all intents with Russia.

He has allowed the Palestinian guerilla forces free rein in Jordan – as a militia with armed parades, etc.

He has now even allowed plane highjackers to land in Jordan and transmit their demands for the liberation of captured assassins.

That is your noble host, your ham pal, whom you feel obligated to pay off for a pleasant visit. I reiterate, you have fooled no one, and as others have said, your editorials stink especially when they dabble in politics outside the field of ham radio. Please omit call and address; I don't need assassins on my tail.

Max Sherr
Jamaica NY

Since you are wrong on every count, it would seem that you have not done your homework. If you will open that vault and send a dollar we will send you the Quaker book which will give you the actual facts on all of your allegations. My "pal" Hussein has done everything within his power to stop the terrorists, to the extent of a civil war with tens of thousands of casualties. The military government was not set up until the civil war broke out as Hussein tried to curtail the commandos, before your letter was written. It is Egypt, not Jordan that is allied with Russia. Jordan has received no Russian aid that I know of. Every report of the highjacking emphasized that the Jordan army was powerless to do anything for fear of repraisals on the hostages. Don't be afraid of assassins, only hoots of derision from fellow amateurs who are less biggoted and more interested in facts than hate.

. . . Wayne

FM in New England

I own a Varitronics 1C-2F and so far have been very pleased with it. This is set up with .34–.94 simplex. This leaves four more positions left for other crystals.

I am interested in mobile through out the New England states plus N. Y. What additional crystals would you recommend to key the greatest number of repeaters in these areas?

Also I would be interested in finding out the best way to keep up with information on new repeaters. I am the proud owner of a subscription to 73 magazine and the April *repeater directory* issue is always in the car with the mobile rig.

The men at 73 should be proud of the fact that they run the finest ham magazine in existence.

Harold A. Chamberlin, Jr. D.M.D. W1PFX
2 Old Sudbury Road
Wayland MA

Best bet for frequency "sets" is .34–.94, .94–.94, .34–.76, .76–.76, .31–.88, and the last channel blank, for crystals you might need for a specific area you want to visit (such as .34–.88 for LI, .37–.88 for Staten Island, or .37–.76 for Northern N. Y.).

Tech Aid Group

I'd like to become a member of the 73 Technical Aid Group. I'm a college student hoping to major in electrical engineering, and I'd like to help Novices with their trials and tribulations. If there's any other information I have to supply you to join the group, please let me know and I'll forward it.

Bob Perlman WB2VRW

73 for the Blind

Somewhere in the September issue I read about tapes for people with poor sight, to cover the course for the General ticket. I have gone over the issue twice and do not find the article. I have a friend that has a Conditional ticket and is anxious to get the General and I would appreciate the information regarding these tapes. This man is 90% blind.

Arthur T. Becker WA4QZL
R.R. 1, Box 622
Avon Park FL

73 tapes for the blind may be obtained from "Science for the Blind," 221 Rock Hill Rd., Bala Cynwyd PA 19440.

. . . Ken

CW Simplified

Just this week I started my two sons (at their request) ages 13 and 15, on their way to a Novice license.

I had been taught the code years ago by a Navy Wave. The one thing she impressed upon the class was that code is a useful method of communication in which speed is secondary compared to good clean transmission.

The accent was on uniform dits and dahs within the character and uniformity of spacing between characters. Faithfully following rules created code that "sang."

One interesting point stressed was that in the "normal range of hand-keyed speeds, from about 7 to 18 wpm, the speed of formation of the character should never vary. What should vary from speed to speed was the length of the space *between* characters. This had the virtue of tuning the ear to a code character that did not vary with speed of transmission.

KW BALUN KIT STILL ONLY $5!
The AMIDON Toroid Balun Kit makes a modern, compact antenna transformer that can be wired for either 4:1 or 1:1 impedance ratio. The balun is ideal for use between a coaxial feedline and a balanced antenna. It reduces coax radiation and properly balances the energy for application to the antenna's feedpoint. The balun also acts as an isolation device and removes the capacity of the coax from the antenna which extends the low SWR frequency range of the array. Baluns made from this kit can be used to advantage on these antenna types: Dipole, Quad, Beam, Inverted Vee, Windom and Folded Dipole.

In listening with a new ear to both the Novice and regular CW segments, it is readily apparent that few people have been exposed to what I have found to be this truth: As the speed of transmission lowers the dits and dahs grow longer and longer, making very difficult copy and failing to train the ear for a true code sound.

The CW bands would clean up considerably if this point could be widely made.

Allan S. Joffe W3KBM

You're Never Too Old

My case history as an amateur radio operator: My first QSO was May 25, 1963, when my age was 74 years, and over the years since that first QSO many close friendships have developed.

In the frames below the call letters W4VGJ are licenses received from the FCC since November 30, 1967. For the reason that the size and poor quality of the picture make reading impossible, they are described.

From left:

1) Amateur Extra Class License dated September 23, 1969.
2) Amateur Extra Class Operator License Certificate, Number AE-6-432, dated September 9, 1969.
3) FCC Commercial Elements 1, 2, 5, Radio Telegraph, Number T3-6-245, dated August 6, 1970.
4) FCC Commercial Elements 1, 2, Radio Telephone, Number P3-7T-4829, dated November 30, 1967.

and

FCC Commercial Elements 1, 2, 9, AM-FM Broadcast Station Operator Authorization, dated August 26, 1968.

The enclosed picture was taken Aug. 20, 1970. My age is 81.

Henry B. Miller W4VGJ
PO Box 1131
New Port Richey FL

FM Anthology

On March 13th of this year, I sent 73 a check (#373, Jensen Beach Bank) for three dollars for a copy of your FM Anthology. Some time passed, and no book was received, although I did receive the canceled check, indicating it had been received and probably spent on a couple of six-packs...

In Orlando, at the hamfest, I spoke to you folks about it, and you said that printing had been delayed, and I should get a copy soon. Wonderful.

Now I see in this month's issue of the world's greatest ham magazine (otherwise known as Green's Folly...) that the books are finally off the presses. But...there are only 500 in print, and everybody had better hurry and send in their three bucks, cause Wayne's running out of beer.

Now I'm worried. Maybe, I think to myself, they'll get rid of all 500 copies of the thing, and forget about me completely. It's keeping me awake nights. Every day I look in the mailbox hoping...but there's nothing there. Except moldy copies of other magazines containing such thrilling articles as "How to Adjust the Catwhisker on Your Receiver to Copy Sideband."

So. . .how 'bout sending me ONE copy of the thing, and end this long agonizing suspense?

Bill Britton WA4IHH
PO Box 707
Jensen Beach FL

OK. The anthology is on its way. For the hundreds of people who have been writing, the anthologies were held up, but now Volume I (at least) is printed, bound, and in the mails. Volume II is not yet printed, and will probably be delayed for another few months. Volume I is made up of the early large issues of FM Bulletin, and it covers the period from Feb 1967 to Feb 1968. The book is a verbatim reprint made by photographing the original bulletins. The price is $3 while the supply lasts.

Volume II will comprise articles from the later issues. Since it has not yet been printed, readers are requested to hold their checks for Vol. II until publication is complete.

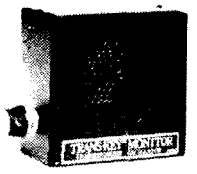
. . . Ken

I would like to bring to your attention a possible ambiguity in the advertising of the FM Anthology in 73. I ordered my FM Anthology from the advertisement on page 71 in the May issue of 73. There, in a black bordered box, both Volumes of the FM Anthology are listed at a price of $3 for the two volumes *together*. In the order list at the bottom of the page, the two volumes are listed singularly as "FM Anthology . . .$3." However, on page 85 of 73's August issue, the black bordered box again appears, but this time the two volumes are priced at $3 *each*. Yet, in the order list at the bottom of the page, there is still the singular entry: "FM Anthology . . .$3." Finally, in your September issue, which I just received in the mail, only Volume I of the anthology is listed. My question, of course, is, just what is the price of the two volumes of the FM Anthology?

I have recently acquired two FM units and am at present holding up their conversion to 2 meters until I receive the FM Anthology for the information contained therein. Please advise regarding this confusion, for I am highly desirous of obtaining both volumes.

Gary D. Maples K9VTE
854 North 12th Street
Manitowoc WI

Confusing ain't it? When we first got started with the FM Anthology, we were going to make it one little book with a few selected articles. But we had so many requests for complete back issues of FM Bulletin that we decided to include all of them that were reproducible in a single volume (Vol. I). When Vol. II is printed, it will include all important articles from late issues of FM Magazine. Each volume sells for $3, and consists of article reprints exclusively.



. . . Ken

Repeater Improvement

The Antenna Separation article (September 1970) had the main solution to my problem about close-spaced 2 meter FM repeaters. However, it will cost us some money to get the necessary towers to get the proper antenna spacing both at the Glade Park repeater (portable) and the Redlands repeater (at my home).

Before I can put up a strong self-supporting tower at my house I will have to check with the Mesa county building Code first. If I can't put up a 50 or 60 ft tower here, all I will then be able to do is install a flea-power (up to 5 watts) repeater for the ".34–.94" combination for the convenience of the "tourist" hams on 2 meter FM. For our *search and rescue* work we will maintain the 145.32–146.94 MHz repeater(s) both at the Glade Park and the Redlands sites. I think the suggestions under "The Last Step" (page 53) are very good and regardless of the frequency spacing, we are putting those suggestions into effect. All in all, the article is *super excellent!*

Nate Bale W0PXZ
PO Box 1494
Grand Junction CO

Repeater Snobbishness

In reference to the *Mr. Virgo Himself* editorial (September 1970), regarding clubs that are slowly tightening requirements for membership in repeater groups, what exactly can I expect as a newcomer to 2 meter FM operation? I have purchased old equipment and worked like a dog to make it work, and now I hear I may expect the "cold shoulder" from repeater operators.

My chief interest is operating through the repeater located at Concord, N. H., as I live near Boston and travel every weekend to Lake Winnepesaukee. I wonder if you might be able to answer these questions: (1) Are the Concord repeater operators hostile to newcomers? (2) How can I get in touch with the operators to find out if they will accept a new membership? (3) Is this an "open" repeater?

Thanks very much for your time. I feel that you people are the only ones from whom I can hope to get honest, unbiased answers. I have, by the way, lost all interest in the ARRL, its policies, its politics, its publications, and in general, all that it stands for. Keep up the good job!

Douglas A. Chisholm WA1BLG/1

The Concord repeater is W1ALE, and it is operated by Tony (W1TNO). The fellows on the repeater are quite friendly and go out of their way to be congenial to newcomers. The repeater is open, and no strings are attached. If you wish to become a member of the local repeater association, you can usually contact Tony by calling him on 146.34, the repeater input.

. . . Ken

I sympathize with the ham in Decatur, Georgia – he got turned down by the local repeater club. I got in the local club OK – I paid up for both my wife, K4BGU, and myself, K4ETZ.

Latest development is that one of the local boys who built the Charlotte, NC repeater (W4BFB) took me to task for chewing the rag with a local friend too much. "Sounded like 75," he sez. Told the fellow that nobody seemed to want in or was using the frequency – and we were letting the repeater "tail out" on every transmission to let any possible breakers in. The upshot of the whole thing was that the Charlotte repeater was shut down, I got a letter telling me that I was about to be "tried" for various offenses, and I was about to be shoved out of the

club. But for an estate settlement and an upcoming gallbladder operation, I would have looked forward to the "trial," as the whole thing looked like beautiful grounds for a libel and/or slander suit, not to mention bringing into the open the fact that the *club* had paid for the repeater, not the two who control it and it was about time we stopped bowing reverently in the direction of Myers Park every time we use it! Sure, have "private repeaters" – if the FCC will let anyone get away with it, but .34–.94 must remain open to all comers, period.

Incidentally, I wonder what would happen if someone put in a repeater on, say 146.34 to 147.3? Would a Technician transmitting on .34 wind up in the soup? FCC Rules make it look quite likely. Deliberate jamming is dirty – but a side-by-side repeater operation to another freq above 147 might be the answer to the cliques!

I am a firm believer that any club that either turns down or ejects a ham on other than bonafide legal grounds should be subject to a going over by the attorney general on the usual "discrimination" grounds. Color has nothing to do with it – if the club is to be tax-free, it also must be nondiscriminatory.

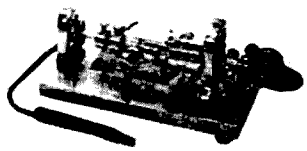
An Orchid or Two

As the author of "The Consummate Console," it was certainly a pleasure to see how very professionally 73 produced the final article and the results certainly justify my time invested in both the building of the unit and the writing about it.

Thanks for doing a fine editorial job. The magazine is improving with each issue, and I'm happy to be associated with it.

Dee Logan WB2FBF
21 Judith Street
Nanuet NY

Your technical articles are *the best* that I have ever seen and your theory series is superb! I'm too broke to have a subscription to 73 but I buy old copies and read them cover to cover – especially Wayne's editorials.



Bill Kresl WB9BBC
1109 Sherman
Janesville WI

My subscription to 73 should precede this letter by a day or two and I thought I might include a thought or two on becoming the proud owner of a share in what seems to me to be the most needed boost to ham morale that has appeared on the scene in a while. I think 73 is the innovation which could help to recoup and develop what would appear to be a sadly declining spirit in the ham fraternity All we need is a new national organization, for which 73 could be the house organ, and we would be ready to go down the road.

Congratulations to Dave Mann for an outstanding bit of editorializing (*Leaky Lines*, issue 118). I wonder how many of us medium-generation-gappers would have the courage to so aptly express the ideas put forth for consideration. I agree 100% with the very fine content of the material and concur wholeheartedly with the

73 Double Bonus

I am a subscriber. I like the magazine. It is however very difficult for me to understand why you waste valuable space which could be sold to an advertiser by carrying the "73 Reader Service." Three issues ago I marked three boxes for further information on advertised products. To date I have never received anything from any of them, which leads me to believe that my request was never processed and probably went into the wastebasket. Three weeks ago I checked a single box so far I have heard nothing.

Hobby Band

Relating to creation of a 220 MHz beginner band, I am astounded as for years I have advocated there be some type of band for beginners. The FCC rules as now set up help create disrespect for law and order. When we have conditions which breed the CB cult, etc. and $20 filing fees which only make the CB'ers more lawbreaking (why pay when you can do it for nothing. . .) and so forth – there is something serious and wrong. However, I have never been able to get Wayne to accept this line of thinking, and for him to all of a sudden come out in favor of doing something to help ham ranks and manufacturers. . .well I am shocked and wonder more than anything else who talked him into it. And, I am also led to question Wayne's honesty in saying in print, "hey, fellows, here is this great idea I got," when in fact others have been pressing modified forms of that idea on him for so long they are tired already. . .

Art Brothers W7NVY
Box 2124
Reno NV

Wayne never claimed authorship of the idea – he claims only to back it as published.

FM in Germany

Since we have tremendous ragchewing on the FM channels here in Germany with transmissions in the hours I would appreciate it if you could investigate the possibility of sending me a tape on any of the internationally used recording speeds with a typical FM channel taped in the U.S. I would return the tape as soon as possible or could also furnish you with a tape if that would be more convenient.

This ragchewing with long transmissions is also practiced on the commercial channels here

(taxis, etc.), as well as by the police, so that nobody can understand here that your repeaters limit transmissions to one minute or so.

Hanno Knorr 552-56-1321
DL 1 LV
% Neckar Rod & Gun Club ECN-950
APO NY

Perhaps our readers can help. As to the ragchewing, someone should suggest the possibility of an emergency occurring in the middle of a long transmission. One longwinded ragchewer could tie up a repeater so that it would be unusable in such an event. Ragchewing is great . . .just allow a dropping of carrier every minute or so to accommodate unexpected contingencies. . . . *Ken*

The Great Controversy: IL

It is about time we should speak up. This applies to both oldtimers and new fellas. Rather than raise a fuss, we sit back hoping the right thing will turn up for us. I have been watching the Incentive License (IL) fracas and finally decided to say my piece!

Having been a member of ARRL for many years, I was one of those who thought ARRL was for the ham – but its manner in railroading through the licensing deal caused me to drop out two years ago. On such a serious subject an action should have called for a membership vote. Hence, I can only deduce they sold us down the river. At the same time, though, they have done some good during past years and we should recognize that for what it is worth.

I would like to suggest a plan regarding this (IL) mess we are in and hope that you will take time to evaluate with serious thought. We all know that one person or a few do not have a chance of swaying FCC and I doubt if any one portion of the IL ruling could be altered to favor one group of hams. By the same token, you can't barrel into FCC with a tirade in what we consider the unfairness they have created by their ruling and law concerning IL. They are in the driver's seat and you might as well accept the decision; however, diplomatically approach them on a different angle. "Incentive" is a word that implies something to work for, not to take away what you already have earned, and then say "If you wish to have your frequencies back – take the highest license exam there is and pay us a fee!" It was quoted in one paper remarks to the effect that FCC could gain so much money by all the hams rushing to pay their fee and get back their frequencies taken from them. What a farce! I think by now statistics will prove to them that this is not the case. IL has proved to be the saddest excuse of eliminating many oldtimers and potential hams.

Let us consider what must be done to make satisfactory changes for all without the degrading aspect. The best plan in my opinion would be for FCC to revert back to all conditions as to frequencies, allocations, etc. prior to IL. This puts us all back on an even keel. Then offer a plan that is a real incentive. Broader the phone bands since this phase of operation is jumping ahead by leaps and these boys should have additional room for expansion. After all, the Canadians' phones are messing up the Novice bands – move the Novices down 50 to 100 kHz for the phone boys on these two bands. Add to

this 50 kHz phone expansion on 14 and 21 MHz. FCC could even go so far as to offer CW fellas a new 25 kHz segment (6975 to 7000 or similar) for incentive. At least offer some real incentive to hams over and above what they presently have.

Now that we know what line of thought to pursue, how does one approach FCC to get a favorable hearing? In preparation – first it will take thousands of active and inactive ham signatures who want to see real justice done. The 73 organization has taken one step with its half-sheet tearout form to be returned to 73 mag (September 1970). Now arrange for a special meeting with FCC by a group of amateurs selected by vote of U.S. hams. IL could then be planned with fairness. ARRL had this chance if only they had given their members the right to vote (along with thousands of hams who were not ARRL members).

I'm sure that proper presentation to FCC with signed statements would cause them to reevaluate their incentive licensing program.

W. Dale Marshall W7DJU
3208 Plymouth Drive
Bellingham WA

I would like to get some thoughts off my gut. First, I hate IL, I don't belong to ARRL any more because of their part in it.

I would like to see ham radio put back like it was before November 1968; it would be a lot more fun for me and those to follow us.

G. L. Burkett

Rudeness with Reason

I am writing to apologize for our rudeness when we walked out on your speech Saturday night at the North Alabama hamfest. My husband and I were looking forward to seeing you and when he felt slightly bad before we arrived he said he wanted to see you too much to let a little pain stop him. The pain became too much to bear so we had to leave. It turned out to be appendicitis. He's doing fine now that his appendectomy is over.

I know he was sorry to miss you, and I think he would want you to know that he left because of illness and no other reason.

Though I'm not a ham I find 73 a very interesting magazine and the editorials refreshingly outspoken.

Sally Taylor WB6BDL/4—XYL

QSY Anyone?

Both Wayne and Ken have refreshing approaches to various subjects. Much food is offered for thought. I don't always agree with the viewpoint(s), but give 73 credit for taking a stand on issues.

Rather belatedly, a reply to Dave Mann's editorial describing two OTs and their experience with W1AW coming on frequency: It seems to me that it would be rather impractical for a station such as W1AW to check *each* frequency

on which it simultaneously transmits since there are so many, a problem of rather some magnitude would evolve and possibly more if transmission on any single frequency had to be delayed.

W1AW has been around a long time – as long as I can remember and longer than most of the hams today. It carries on a service for which many are grateful – when *they* can copy through the QRM. The times and frequencies of transmission are published as they have been for many years!

How quickly so many years of good are forgotten in a fleeting moment of aggravation or disagreement! Are those *particular* minutes, that *particular* frequency so precious they cannot be surrendered for a helpful service unselfishly given?

Paul Pagel K1KXA
4 Roberts Road
Enfield CT

What's Wrong?

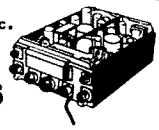
Repeaters on calling, monitoring, and emergency channels such as the nationally recognized 52.525 and 146.94 MHz, in particular. These actually hinder amateur radio, as they encourage poor operating and maintenance practices, a let-somebody-else-do-it attitude, cause untold interference to simplex operations, sometimes at far greater distances than the repeater normally covers, and in the end completely discourage simplex operation and promote a "communal" type of operation.

Poor operating, maintenance, and construction practices: To go into detail, the stations that have no way to measure their deviation, so merely set it way too high to be sure; They don't seem to know that they lose, rather than gain, performance through this practice. Power in excess of that necessary to do the job at hand: Experience in this mode of operation will tell anyone who is observant that power outputs in excess of 60 to 90 watts is simply that much more useless QRM; Sure, you'll get some nice signal reports, but what good is a signal report from a station with a sick receiver? Why should he bother to repair his receiver if he can hear somebody full quieting? If you have adequate antenna height, you can cover hundreds of miles with 25 or 50 watts; if you don't have the height, why QRM stations you can't hear because of your poor antenna?

Operating practice: There seems to be more and more of the "lumbago net" type activity these days on FM; The "long talker" will always be with us, but they should be discouraged from cluttering a channel with their hems and haws for hours; The way to do this is to use terse operating procedure yourself, and don't talk with the sciatica gang; The same goes for the drunks – amateur radio can live without the stigma of alcoholism. The Senile Operator: I don't know, but it sure gets hard to listen to by the hour.

Lastly, the attitude that FM is only good for 10–20 miles; Rats! You get out of it what you put into it, just like anything else. Of course, if you can't seem to get the antenna up over 20 ft, or afford a good feedline, just crystal up for the local repeater and they'll hear you 200 miles away while you're discussing your lumbago with Joe down the road. Fine. Rental Radio – just what ham radio needs! It's the next thing to communism – but don't say that to a repeater owner or user!

Bill Harris K9FOV
414 Bomberding Ave.
Lafayette IN



You may have a few legitimate grievances, Bill, but you're living in the past if you think 146.94 MHz is nothing more than a national calling channel. Whether we like it or not, whether we agree or disagree, whether we approve or disapprove, the plain fact is that 146.94 MHz is first a national repeater output frequency. The amateurs of today have made it so.

73 Reader Service Coupon

Now we don't say that every single reader must buy every last product advertised in 73. We believe that, but we don't say it. The very least every reader can do is to put on a show of interest in the products herein advertised. To make this a simple task, even for the laziest reader (now there is a contest for you!), we have cleverly arranged the advertising index to double as a readers service coupon. All you have to do is tear it out (or photocopy it) and send it in with the appropriate boxes marked. (We have a prize for the most boxes marked . . . a silent prayer of thanks from the publisher). We'll accept postcards, slips of paper, or almost anything else that lists the companies you want to hear from and your address.

No one likes to go into a store without buying something, right? It is the same with these information requests. You will be expected to buy something. Oh, it doesn't have to be a $50,000 antenna system, but it should be something modest . . . a transceiver . . . a linear . . . you know. We'll leave the decision up to you, knowing that we can trust you to do the right thing.

And we are definitely not saying that the use of this service coupon has any curative powers, but we cannot but notice that many readers report remarkable relief from simple backache, headaches, lumbago, and acid indigestion after sending in their coupon. Why take any chances?

CHICAGO OUTLAWS HAM RADIO!!

CHICAGO AMATEUR CLUB BRINGS SUIT

Chicago. Under city zoning ordinances, Chicago has forbidden amateur radio stations to be set up in residential areas. According to information published in the Chicago Daily News, the ban can only be waivered on payment of a special $100 fee.

Proceeding on the grounds that such anti-ham legislation is unconstitutional, a group of Chicago amateurs (the Chicago Area Radio Club) filed suit in district court, charging the city with attempting to regulate a service that is already being regulated by the federal government. The suit seeks to have the U.S. district court enjoin the city of Chicago from enforcing its ordinance and from collecting fees for waiving such ordinances.

In supplying this information to 73 News, Art Housholder (K9TRG), manager of Spectronics, Inc., a Chicago area ham radio firm, said the action of the city and the counteraction on the part of the CARC were topics of

U.S. Navy Radioman First Class Larry Hollingsworth sets up personal phone patches for crew members aboard the frigate Yarnell, reducing the impact of transglobal separation between family members.

discussion at club meetings around Chicago and on ham radio nets. Most of the comments, he indicated, were directed against the inequitable city ruling. He also expressed concern that should the court favor the city rather than the amateur operators, other metropolitan areas might follow suit, dealing a crushing blow to amateur radio.

NO-MONITOR REPEATER OPERATION PROPOSED

The editor of 73, Ken Sessions (K6MVH), has submitted a proposal to the FCC that calls for toned repeaters to be allowed to operate without the requirement for UHF monitoring. Under present rules, no remotely operated repeater may be used unless the specified repeater licensee is monitoring from the UHF control point stipulated on his license. The rules make it impossible for the sole owner of a repeater to operate his repeater from a mobile or from any site away from his control point.

Sessions' proposal would make it legal for continuous monitoring to be abandoned when certain fail-safe measures and tone control have been incorporated into a repeater system. Tone-burst and whistle-on repeaters, under the proposed ruling, would require no fixed-control-point monitor as long as effective automatic measures have been incorporated into the repeater design to suspend operation of the repeater when its emissions deviate from the rules of the Commission. Untoned repeaters would continue to fall under existing rules.

MODERN NAVY USES HAM RADIO AS MORALE BOOSTER

Lucius Seneca, an ancient philosopher, once said, "It is through the essence of letters that friends are, in a manner, brought together."

Although Seneca was talking about letters one writes, his thoughts can also be applied to the call letters of ham radio station WBØBDH. aboard the guided missile frigate USS Harry E. Yarnell, presently circling South America on Unitas XI operations.

Bringing people together via ham radio and telephone patches is the off-duty "pleasure" of radioman Larry Hollingsworth. "It is a pleasure to be able to set it up so one of the men on the Yarnell can talk to his wife or girlfriend back in the States," emphasizes Hollingsworth.

Running WBØBDH is Hollingsworth's hobby. His main job is radio watch supervisor and controller at Yarnell's communications division.

Instrumental in establishing WBØBDH before Yarnell departed her home port at Newport, Rhode Island, Hollingsworth obtained an FCC license and was designated supervisor of the amateur radio activity.

"It has really been fantastic," Larry says. "We have been gone two months and I have completed almost 400 calls. It is a real morale booster when we are 8000 miles from home."

Unitas is an annual training exercise involving the United States and the major maritime nations of South America. Larry and the Yarnell will circle South America and return to the United States in mid-December.

A real asset of the service has been demonstrated in situations where an emergency is involved. One chief petty officer on Yarnell received a letter from his wife saying they had suffered a very serious fire in their home. "The letter lacked many details which were important to the chief so we placed a call home via the ham setup," Hollingsworth stated.

A Navy wife, who is presently living in Norfolk, Virginia, and whose husband is on the Yarnell, in a letter to the Yarnell's commanding officer, wrote: "Larry's efforts have certainly helped bridge the miles between my husband and myself, and those four wonder words, 'I love you – over,' have kept us close in spite of the miles that separate us. It is warming to know there are those who understand the voice of a loved one can make a long separation at least bearable."

"We really have received outstanding cooperation from ham operators throughout the United States," the radioman said. "Almost all phone patch stations we contact seem more than willing to help us place our calls."

He does encounter the humorous aspect also. He was talking to an operator in the midwest one evening and the man agreed to make phone patches for Yarnell men. However, the operator's wife was using the phone and after ten minutes of idle chatter over the airwaves, Hollingsworth finally had to thank the man and sign off.

Originally from Albia, Iowa, Hollingsworth presently makes his home in Middletown, Rhode Island, with his wife Lynda and two children, Lee and Lynette.

Larry is anxious to talk to any operators in the world who would like to contact him on the air or by writing to him in care of the USS Harry E. Yarnell (DLG-17), Fleet Post Office, New York. Phone patches to the States are actively sought and QSL cards are available.

GALAXY MOVES TO LINCOLN: Something Big in the Offing?

Lincoln NB. The acquisition of Galaxy by Hy-Gain is now complete, according to R. A. Kobold, spokesman for Hy-Gain Electronics. The company has brought all Galaxy's operations from Council Bluffs, Iowa to Lincoln, Nebraska. Kobold hinted of some sparkling new products to be evolving from the merger, but would not be specific as to detail.

Galaxy watchers seem to think an unveiling of something new could take place at the big SAROC convention in Las Vegas this coming January. According to reports from within Hy-Gain's executive offices, the company has reserved six booths for the occasion. This "extravaganza" attitude could point to an announcement of something the company feels spectacular.

AMATEURS IN ACTION

Coast Guard Commends Ham For Meritorious Service

Washington, D.C. Admiral P. G. Prins has personally expressed thanks on behalf of the U. S. Coast Guard to J. P. Corrigan, a radio amateur who provided communications with a ship at sea during a personal shipboard emergency.

In a letter to Corrigan, the admiral reported: "On the afternoon of August 26, it was reported that the radio operator on (the ship) Stella Lykes had apparently suffered a heart attack. This denied normal communications with the ship and required that all information be passed through the ship's amateur radio. From that time through the evening of August 29, when the ship arrived in Honolulu and transferred the patient ashore, you maintained highly effective communications, passing medical advice for the U. S. Public Health Service, rescue operations information for the Coast Guard, and port arrangements for the ship's agent, Oahu Railway and Terminal Warehousing Company."

By way of expressing the appreciation of the Coast Guard, Admiral Prins said, "Your diligence and constant willingness to help are noted with pleasure. I feel that this has been an outstanding display of the humanitarian spirit of amateur radio operators everywhere."

Copies of the admiral's letter were sent to the Lykes Brothers Steamship Company, employer of the cited amateur, to Oahu Railway and Terminal Warehousing Company, and to the U. S. Public Health Service in Honolulu.

EARLY 73 BRINGS $25!

The January 1961 issue of 73, good copies of which sold just three years ago for as little as $10, now is bringing $25. This issue, one of the rarest of the early 73 issues, was bid to the $25 price at the ham auction at the ARRL National Convention. This issue featured the first published circuit for the RCA Nuvistor and was in wide demand during the early 60s. Now, with JFETs and things, the issue is more of value as a collector's item. The article on using the Eico modulator with the Johnson 6N2 also helped make that particular issue rare.

HAM OPERATOR HELPS BOY GET CRITICAL OPERATION

(Reprinted from Florida Skip)
by WA4ABY

Josef Darmento (W4SXX) has won the recognition of his community and the plaudits of the ham radio fraternity for his assistance in helping a small Italian child receive a crucial heart operation. His able use of ham radio paved the way for 4-year-old Fabio Piampiani to undergo a heart operation last month by Houston's famed Dr. Michael DeBakey.

On June 9 Joe intercepted an urgent plea on 20 meters from I1BAX, Roger, a doctor in the Adriatic Sea fishing village of Civitanove. Roger outlined to Joe that the child had an atrophied right ventricle and would die if he didn't get an operation within three months. Responding, W4SXX then contacted his wife visiting in Austin, Tex., who in turn talked with Dr. DeBakey in Houston. The famous pioneer of heart transplant surgery gave his tentative approval for an operation at no charge, if the child could be brought to Houston.

Darmento, a Merritt Island resident and a physicist with the Air Force Eastern Test Range, relayed this information back to Italy and arrangements were made for the boy's trip to the United States. Concerned Italians donated nearly $6,000 so the boy could receive another chance at life. Finally, during early July little Fabio Piampiani made the trip from Rome to New York and on to Houston. W4SXX enlisted the aid of three New York hams

HAMS CITE

IN CONGRESSIONAL RECORD

*Washington, D'C'*The Honorable Emilio Daddario, Connecticut appointee to the house of representatives, pointed to the service of U.S. radio amateurs during a meeting of the house in September. From the Congressional Record comes the account of Daddario's speech, which said in part: .

. .I rise today to call attention of the House to the valuable services performed by amateur radio operators — "hams" as they are frequently called. Operating their own private radio stations, hams render emergency assistance in providing communications during disasters such as Hurricane Celia. We have all read accounts of such activities and are well aware of the invaluable help these volunteers provide. What is not so well known is the continuing assistance hams provide in alleviating a most human problem — the loneliness and suffering that comes from the separation and lack of communications between our servicemen and their families. Those of us who daily see our wives, children, and close friends forget that there are hundreds of thousands of young people whose contact with their families is limited to letters and occasional photographs. Like the concerned public servants they are, hams have stepped forward to lend their aid and provide radio communications facilities so that servicemen abroad can talk to their loved ones at home. Using "phone patch"

OVER 2000 ATTEND ARRL NATIONAL IN BOSTON

by W2NSD

The Boston ARRL National Convention was an unqualified success this year with well over 2000 amateurs and their families in attendance, setting a record for ARRL National Conventions in recent years.

The sad part was the tiny display area, a far cry from a few years back when most of the manufacturers in our hobby supported these National Conventions. Outside of a few distributors, the main displays were by Drake, Mosley (Carl himself was there, by gosh!), Cushcraft (Les Cushman was there!), National, Swan, Signal One, etc., plus a few newcomers such as Ten-Tec, Ehrhorn, Lee, etc. Even the most avid scrounger of data was hard put to spend more than a few minutes in the exhibit area.

As outlined last month, pressure from HQ prevented the convention committee from permitting any 73 personnel from participating in any way in the programs. Fortunately 73 was able to get a small auditorium room for one of the convention days and hold several FM forums, meetings and discussion groups, show slides of Jordan, discuss incentive licensing, and keep conventioneers from starving to death with good New Hampshire freshly squeezed cider and homemade donuts. Many thanks were received for the feed from convention goers with either stunned pocketbooks or stunned taste buds from eating at the local restaurants.

The proliferation of local hamfests and conventions has put a strain on the larger manufacturers, but perhaps they should make every effort to save enough time and money to support a national convention, for without their support a convention looks more like a small-town picnic and is disappointing to amateurs who have come from afar for the expected gala affair.

Lele Defilippis (HB9AMY), at right, poses with two others of his recent all-band DXpedition to Liechtenstein. QSLs are to be mailed to HB9AMY. Box 768, Lugano 1, Switzerland.

(K2JSO, W2IOM, and WB2CBP) to assist the boy's mother in finding the right plance from JFK airport to Houston.

Sorrowfully the child died on the operating table July 12. But at least the boy had a chance at life he wouldn't have had if it weren't for ham radio.

In an editorial entitled Humanitarian Ham, the newspaper Cocoa Today said, "We think this is a fine example of man's humanity to man."

For his pivotal role in this outstanding example of the good in our hobby, Florida Skip last month saluted Josef Darmento as "Ham of the Month."

equipment coupled directly to their own radio receivers and transmitters, hams call friends and parents of servicemen on the telephones and let them talk to their absent soldier in Vietnam who use military radio facilities over there. Acting as the vital link, the ham provides a much needed human contact between individuals separated by the war.

RADIO AMATEURS "FILL IN" FOR LOST LANDLINES

*Cuba, NY.*When a work crew accidentally cut through an underground telephone cable recently, the local civil defense group was alerted immediately, bringing to life an organized communications network revolving around a 2 meter FM repeater.

According to Gailerd Perkins (WB2IDQ), eleven stations, working through the Mt. Chaos repeater (WA2UWT). were deployed at key positions to plug what the Ocean Times Herald referred to as the "telephone gap."

Volunteers manning mobile radios supplied through the CD office's RACES network – and some CB'ers – patched together an emergency network by which the Cuba Memorial Hospital and the fire, police, and ambulance services of the community could maintain instant contact.

A local CD official said that no real emergency arose during the phone outage, but the network was ready and operative "jus[illegible]e."

INTERNATIONAL NEWS

Swiss Government Okays FM Repeaters

Switzerland. The Swiss Government has given the go-ahead to amateurs who want to put up repeaters on the 2 meter and 450 MHz amateur bands. Due to the narrow operating spectrum in the 2 meter band only the input or output of a repeater can be placed in that band: the other end of the repeater system must be placed in the 450 MHz region.

Swiss amateurs are expected to set up their repeaters with inputs on the 2 meter band where they can make most effective use of mobile range.

MARS Ops Break UHF DX Record

U. S. Hq., Ft. McPherson, Ga.– Bill Byrd (WA4HGN) of Muscle Shoals, Ala., and Paul Wilson (W4HHK), of Collierville, Tenn., set out to break the UHF DX record, and break the world record they did!

Bill and Paul are both amateur radio operators, and members of the Third U. S. Army Military Affiliate Radio System (MARS), as AD4HGN and A4HHK, respectively. Both are inveterate experimenters, anxious to advance the "state of the art" in their avocation

From IARU Region 1 News: "AROUND THE REGIONS"

AUSTRALIA:

The Wireless Institute of Australia has secured permission for the use of slow-scan television on all amateur bands as authorized in Australia. The bandwidth of emissions shall not exceed that of an A3 signal. Identification is to be by call sign in visual form on the televised picture and by telegraphy on the telephony sound channel.

BULGARIA:

The 7th National Convention of the Central Radio Club of Bulgaria was held on 26 April 1970 in Sofia. Delegates from amateur clubs approved the methods of development of amateur radio in Bulgaria. The convention called for further development of SSB telephony and VHF/UHF amateur communications in this country.

DENMARK:

The following information concerning reciprocal licensing has been submitted by the Danish Posts and Telegraphs.

The Danish General Directorate of Posts and Telegraphs is prepared to consider applications from aliens provided that they will stay in Denmark for a reasonable period of time and provided that they have a certain firm connection with Denmark.

case whether a license will be granted or not. If a license for operation in Denmark is granted, this will be done without a renewed technical examination and code test.

GERMANY:

The Distrikt Niedersachsen has plans to establish another training course in Wolfsburg which is supposed to take place during the Easter holidays of 1971. Talks with the management of the Wolfsburg Youth Hostel have already been opened and it is most likely that the course will materialize.

The training will include lectures on techniques, laws, and regulations for amateur radio, and training in Morse code.

GHANA:

The latest edition of "9GI News" reports the tenth anniversary of the inauguration of the Ghana Amateur Radio Society. The number of licensed amateurs in Ghana is now shown as 40.

MALTA:

The Malta Amateur Radio Society has obtained the use of a historic building, known as the Zabbar Gate, for use as its headquarters. The building originally formed part of the fortifications erected by the Crusaders. The

NIGERIA:

NARS reports considerable interest in amateur radio at the Kaduna Polytechnic from where a station is active under the call 5N2KPT. The licensee of 5N2KPT is David Wilcox, G2FKS. It is hoped that arrangements can be made to acquire, without payment of customs dues, equipment suitable to start a club station. Certainly it seems right that an educational institution should be able to obtain a concession from the authorities.

SWITZERLAND:

In Switzerland there were 917 amateur licenses in force at the end of 1969. Membership of USKA at the same date totaled 790 full members and 655 associates.

The regulations governing amateur radio have undergone some slight modifications in 1969. The minimum age for obtaining a license was lowered from 17 to 15 years. Operation of repeater stations is allowed on 450MHz and 2m.

USA:

The Foundation for Amateur Radio Inc., a nonprofit institution devoted to advancing the interests of amateur radio with its headquarters in Washington, D. C., announces the esta-

EDITORIAL

THE NAURU CURSE

by Dan Whitsett W4BRE

Of the 300 or so countries I have worked the past four years, two or three stand out as being unusually exciting contacts. These stand out not necessarily because they were the most rare, but because of the effort I had to put out to get them – or maybe the unusual manner in which they were worked. Just recently I made what has to be one of my two most exciting DX contacts. Nauru is certainly not the rarest catch on the band, but for some reason it had eluded me throughout my DX chasing. I had seen in the various DX columns and magazines where the fellers were occasionally working Nauru, but never once did I hear him. The main reason was perhaps that his operating hours would have meant for me to be on between 1–4 a.m., and I felt confident that someday I would find him on during my regular hours. The months went by and still no Nauru. The call changed from VK9 to C21, and I continued to look for him. Then my confidence began to fade, as I began to read that the only operator there, C21JW, would be closing down for good very soon.

Then I saw in Gus' "DX'er" that the middle of June was the deadline. I had one week to find and work C21JW – a station that I had not been able to find for 27 months.

So, with seven days in which to get the job done, I set my alarm clock the first night for 1 a.m. Listening until 4 a.m., I didn't hear anything of C21JW, WA6FYC, one of the guys I had asked for assistance on the first night of this "mission impossible." He told me that C21JW was on 14.128, and that he would try to break them, and hold him for me. I leaped out of the bed, and like Jim Ryan setting the world's record four-miler, I dashed into the ham room, turning on every switch I could find.

Just knowing that he was on the air, and that I knew what frequency was more than I could handle and still keep cool.

Just as the receiver warmed up, I heard WA6FYC on CW on 14.128. Then some Australian came back to him and said, "Sorry OM, but C21JW just QRT'd, and QRT'd for good, since he's packing up to leave Nauru."

There is no way in the world I can explain my feelings upon hearing those words . . .but I believe every true DXer will know the emotions I felt.

But then, I heard a "break," and a voice said, "This is C21JW, I'm still listening." Oh Happy Day! My heart almost leaped out of my chest. Even though he stood by for WA6FYC I started pounding the keyer, "C21JW DE W4BRE PSE PSE PSE K."

He came back, he came back . . .I've got him! Oh hang on . . .don't have a heart attack yet . . .please hang on until we exchange reports.

He turned it to me, I gave him a report and I was in the process of asking him to listen for me in the

of radio communications. They have conducted endless experiments; designed, built, and modified equipment, much of it furnished by MARS; and tried new techniques in preparation for their record-breaking communications feat on 2300 MHz this summer. Bill, father of three, works for the Tennessee Valley Authority as an instructor of student generator plant operators. Paul, also married and the father of two, is a television broadcast engineer for a station in Memphis, Tenn.

On July 9, Bill drove a panel truck to a place called Sunset Rock near Bon Air, Tenn. Inside the truck was seemingly enough exotic radio equipment to monitor a space flight, and on a trailer behind, looking not unlike a large mechanical turtle, was a specially tuned and rigged 10-ft. dish antenna.

Working from an elevation of nearly 2000 ft. above sea-level, and using an astrocompass to point his dish antenna in precisely the right direction, Bill first attempted to contact Paul on the morning of July 10. Repeated attempts that first day were unsuccessful, but early on July 11 another call brought the looked-for response: "This is *W4HHK reading you loud and clear!*"

The record thus established was for 249 statute miles, as established by aeronautical charts. And the record is now official, having been recognized early in September this year by the American Radio Relay League.

To the uninitiated, the distance may not seem very astounding in this age of moon voyages and globe-girdling communications. But the record set by Byrd and Wilson was at a frequency of 2.3 GHz – approximately four times as high as that of the highest-frequency UHF TV stations on the air in most parts of the United States.

At that frequency, and even at those as much as 75 times lower, communication is normally limited to line-of-sight, or the horizon. And 249 miles is more than 160 miles beyond the horizon in the location used by Bill and Paul.

Also, there's the matter of power. Commercial UHF TV stations routinely use more than a million watts of power to send an acceptable signal 50 miles or less. Bill and Paul communicated over their record-breaking distance using less than 1 kW, the legal limit.

It all adds up to a most impressive achievement, especially when one remembers that it was accomplished by two amateurs using mostly home-built or modified surplus equipment. If the two southern gentlemen who accomplished it will excuse the expression, their feat stands as a notable example of modern yankee ingenuity.

(L-R) A4HHK and AD4HGN. Operating as W4HHK and WA4HGN on the amateur 2300 MHz Band, set a new tropo-scatter distance record on 11 July 1970, when a two-way contact was made between Bon Air, Tenn. and Collierville, Tenn., a distance of 249 statute miles.

Paul M. Wilson of Collierville, Tenn. stands beside the antenna used in his radio moon bounce experiment. Wilson is a member of the Third US Army Military Affiliate Radio System which provided most of the parts he modified in order to build his imposing radio station.

Aliens have to adopt the usual procedure when applying for an amateur license (submit an application to the general directorate). It will always depend on a decision in each individual

members of MARS plan to restore the building and undertake conversion work. A picture of the Zabbar Gate with members of MARS appeared recently in the "Malta Times."

blishment by it of a Hospitality Committee with the objective of providing visiting foreign licensed radio amateurs with an opportunity to meet some of our local active hams and if desired visit a local amateur station.

CROSSBAND RESULTS

WAR, NSS, NPG,and AIR had a combined total of 8,208 QSOs during the twelve hours and forty-five minutes devoted to the military-to-amateur crossband portion of the communication tests. Included in this total were 197 air/ground QSOs made by Navy aircraft on the east and west coast. Commemorative QSL cards have been mailed to all contacts that could be identified. Any amateur who has not received a QSL card confirming his contact should address a request for confirmation to the appropriate station, or Armed Forces Day Contest, Attention: Headquarters, U.S.Air Force, PRCOM, Room 5B531, The Pentagon, Washington, D. C. 20310. This request must include the amateur's call sign, the station worked, time of contact, and the frequency utilized by the military station.

73 GOES TO VIETNAM

The 43 MARS stations in Vietnam and Thailand are all getting copies of 73 now on a gratis basis through the efforts of Alex Scherer A9EU of Ottawa, Illinois. It is hoped that this amateur radio magazine will interest the many operators at these remote stations in getting on the ham bands and in pursuing amateur radio when they return to the U.S.

MERRY XMAS AND HAPPY NEW YEAR from WØCVU, Iowa's most truthful station. Generally on 20 meter SSB. Collins KWS-1 and 75A-4. Telrex Optimum spaced beams. WØCVU, Chas. W. Boegel, Jr., 1500 Center Point Road N. E., Cedar Rapids IA.

TR4 & AC3 just factory checked and alined. First Certified check for $450 winner. David Beckwith, W2Qm,M, Box 226, Pompton Lakes NJ 07442.

TECH MANUALS — R-390/URR, R-390A/URR, TS-186D/UP, BC-639A. R-274/FRR, OS-8C/U, $6.50 each; R-274/FRR, OS-8C/U, $6.50 each; TS-174/u, TS-175/U, TS-323/UR. $5.50 each. Hundreds more. S. Consalvo, 4905 Roanne Drive, Washington DC 20021.

HA-460 AND TR-108, both lightly used, $75 each, ppd. David Welty, 320 N. Blackstone, Tulare CA.

HAM-M ROTOR AND CONTROL, $94.95. Ideal Christmas gift for Dad. RG8U foam coax $.10 a foot FOB. Monte Southward, WB8GZQ, R1, Upper Sandusky OH 43351.

BUY, TRADE, SELL USED RECEIVERS, or trade for new general merchandise. Available HQ-200, 51S-1 SX-122 and BC-799B. 10-day money-back guarantee. 30-day warranty on parts and labor. Steven Kullmer, Evergreen Hatchery, Dysart, Iowa 51114.

FOR SALE EICO 720 xmtr — $45.00; Johnson 6N2 xmtr — $45.00; HA-1 Keyer w/VIBRO Keyer — $65.00;ARC-5 rcvr w/115 VAC p. s. — $20.00; Novice Xtals - $.75; Regency GT-523 mobile C' B' xcvrs — $35.00 each; EICO 221 VTVM — $20.00; AC-1 QRP xmtr — $20.00; P-2 SWR meter — $15.00. Need cash for graduate school. Will ship collect. R. O. Lust, WB9DWG, 320-4 North Tratt St., Whitewater, WI 53190.

TOLEDO MOBILE RADIO ASSOCIATION'S 16th ANNUAL HAMFEST AND AUCTION will be held February 21, 1971, Lucas County Recreation Center, Maumee, Ohio. $1.00 registration. Open table sales. Map and info write: TMRA W8HHF, Box 273, Toledo, Ohio 43601.

GREENE Center dipole insulator, with ... or ... without balun. See November issue 73, page 107.

SAROC, January 7-10, 1971, Flamingo Hotel Convention Center, Las Vegas, Nevada. Sponsored by Southern Nevada ARC, Inc., Box 73, Boulder City, Nevada. Advance registration +14.50 per person accepted until January 4, regular registration at door, includes Flamingo Hotel Late Show and drinks, Sunday breakfast, Cocktail parties, technical seminars and meetings, ARRL, DX, FM, MARS, QCWA, WCARS-7255, WPSS-3952 and WSSBA. Ladies program. Flamingo Hotel SAROC room rate $12.00 plus room tax, per night, single or double occupancy January 3 through 12, 1971. Mail accomodations request to Flamingo Hotel. Mail advance registration to SAROC, W7PRM, Club president. W7PBV, SAROC Convention chairman.

DRAGON FLY ... antenna, for 20-40-75 meters ... no traps ... no compromise ... eight months in development ... one feed line ... SWR one to one guaranteed. Construction drawings $5.00. Box 423, Wakefield RI 02880.

FOR SALE: Heathkit HW 32, $85.00; mint condition. M. Kaufman, 36 Harvard Ave., Brookline MA 02146.

MSI-DTL INTEGRATED CIRCUITS: Guaranteed new — gates $.56, F/F $.72, dual F/F $.92, MSI $2.00, dual Lamp drivers $1.60. Other inexpensive parts. Mitch-Lan Electronics Co., Dept. 7370, P. O. Box 4822, Panorama City CA 91412.

CAPACITORS. 100 MFD at 3 kv. Aerovox or Sprague, 6" x 8" x 14". Single terminal welded steel cans. 2 for $35.00, FOB. W5DAU. Box 1443, Hobbs NM 88240.

FOR SALE — MAKE OFFER: Gonset GSB-100, SSB XMTR; Hammarlund HQ-110C; Homebrew 800 watt linear. John McLean, 5603 N. 12th Ave. Phoenix, AZ 85013

FM CRYSTALS FM-210. They're accurate, by International. Transmit: 146 22, 146.25, 146.28, 146.31, 146.34, 146.46, 146.76, 146.94. Receive: 146.76, 146.88, 146.94. $5 each, singly or in lots. Wayne Green, 73 Magazine.

WEST COAST HAMS buy their gear from Amrad Supply Inc. Send for flyer. 1025 Harrison St., Oakland CA

but I did talk with several Californians who had worked him. I told them of my plight, and asked them to call me if they should hear him.

The next night when I heard someone mention his call, my hopes got up and I called in . . .but he had just left a few minutes before. Knowing he was around somewhere, I frantically searched the band that night, but absolutely nothing.

The fourth night my clock again went off at 1 a.m. Bear in mind that I would only have been asleep for an hour or so, and when the clock would go off, it would scare me half to death. Again I found a QSO where C21JW had just signed out to go look for a friend. I searched the band and found his friend, but no Nauru.

Again the fifth night . . .nothing. The sixth night, same story – and I was beginning to believe I had the Nauru curse.

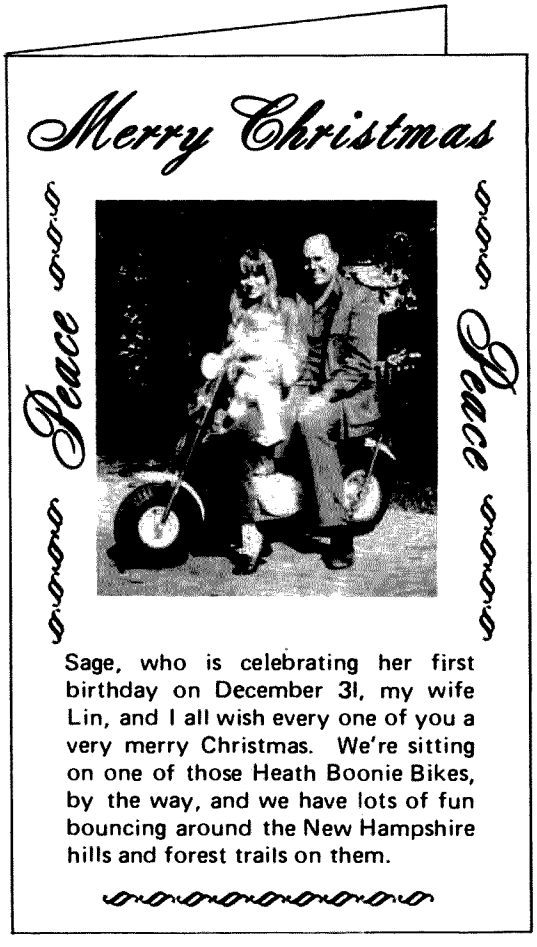
On the seventh night, which was going to be my last try since he was due to leave in a day or so, and since there was no way in the world I could survive this ordeal any longer, I tuned the band for two hours . . .all in vain. Finally giving up, admitting that the Great White Father didn't have in his plan for W4BRE to work C21JW, I staggered off to bed.

I must have only been in bed for 10 minutes or so when the phone rang, scaring me out of my wits; it was phone band, when, forgetting that my amplifier was tuned up around 14.275, Blam! FUSES BLEW! OH NO! I've lost him. I've LOST NAURU. WE HAVEN'T YET EXCHANGED REPORTS.

If I thought I was panicked when 6FYC first phoned me, that was nothing compared with now. I WAS OUT OF MY MIND. Well, I must have set a world's speed record because when I got back on the air C21JW was telling me that he couldn't go to the phone band because he had to leave. Good enough, I was plenty happy just to get the contact.

WA6FYC and I moved up to the phone band, and I was thanking him . . .offering to send him money, my car, my house, anything in appreciation, and mopping the sweat off my brow, trying to regain a little composure, when "Break, Break, this is C21JW."

He had a change in plans, didn't have to leave just that minute, and came up and ragchewed with 6FYC and me for 30 minutes!



What an experience . . .I was dying to tell the people at the office and my other friends about it . . .but no one . . .absolutely no one but an honest-to-goodness true DXer could understand and appreciate this absolutely absurd, insane, and ridiculous undertaking, and why, after it was all over, I would say to myself . . .it was well worth it.

SELL HEATH DX-60A, 5 crystals. Used very little Guaranteed to be in good working condition. Make offer. Arris Sigle, 543 N. 2nd, Osborne, Kansas 67473.

VARIAC, 120 volt, 20 amp., uncased, new $25.00 each plus shipping (25 lbs. each). Brian Sherrett, TUSLOG, Dept. 6 Box 557, APO New York 09254.

TIRED OF "MICKEY MOUSE" TRANSCEIVERS? Immaculate KWS-1, 75A4 (.800 MHz, 2.1 MHz filters) all factory modifications. Coindel, Shure 444. Will demonstrate/guarantee. Top-notch, $1,000. (813) 646-5349, nights.

WANTED: Heathkit HA14 Linear Amplifier with or without tubes, HL9KQ American Embassy, APO San Francisco CA 96301.

Sage, who is celebrating her first birthday on December 31, my wife Lin, and I all wish every one of you a very merry Christmas. We're sitting on one of those Heath Boonie Bikes, by the way, and we have lots of fun bouncing around the New Hampshire hills and forest trails on them.

Director Green?

Many readers ask why I don't run for ARRL director since I know the organization so well and have proposed so many ways of improving it. Frankly, I somehow doubt that the executive committee would waive the bylaw prohibiting ham publishers from running for director, even though they have in the case of ARRL stalwart KØNL.

It would be nice to be able to run for the job and I think I could be a considerable help in bringing the League into the 1970s if I were elected. What, you ask, would I do as a director of the ARRL to improve that conservative old institution?

Better Directors

Probably the first thing I would do would be to try to encourage amateurs to run for director in other divisions of the ARRL who are interested in improving amateur radio to replace those directors who are there for the prestige of the office rather than as true representatives of their constituents. Little can be done to improve the League until at least nine of the 16 directors want to improve it. Right now it seems hopeless.

Sound Financial Basis

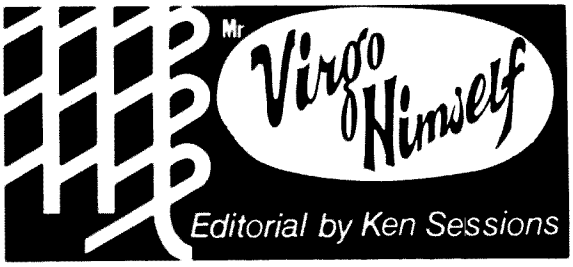
There is no excuse for the League losing money every year! There are many ways to increase income and to cut expenses. By reducing the size of QST by a fraction of an inch so it would fit on modern web offset presses and by using more modern paper a saving of thousands of dollars a month can be achieved. There are many other areas where substantial savings can be made without losing any valuable services. We can see that the League investments are bringing in a maximum return. We can plan ahead for continued nonprofit operation, but an eventual end to the tax-free status.

Washington Lobby

Only when the ARRL has a registered lobby in Washington can it truthfully say that it represents amateur radio. Such a lobby would put an end to the doubletalk excuses from HQ and would give amateur radio the first real opportunity to protect itself in Washington. A monthly newsletter to congress would be invaluable in laying the groundwork for a lobby. Amateurs are making news all over the world, but few outside of our hobby hear about it. We need to beat our drum. It is entirely possible that much or all of the cost of a lobby in Washington could be financed entirely separate from the ARRL, thus keeping League expenses down.

Emerging Nations

The key to the future of amateur radio lies entirely with the votes of member nations of the International Telecommunications Union at Geneva. It would behoove us to keep this in mind and devote some time and energy towards protecting our frequencies internationally. The ITU is presently controlled by the emerging nations of Africa and Asia and the League could be of great help to many of these countries at little cost. It could offer custom-made amateur radio regulations for individual countries, complete with amateur license exams. It could organize expeditions to these countries to explain the value of amateur radio to the heads of the countries and their top officials. Club stations could be organized in the countries, probably in high schools. If equipment is not available it could be arranged to be donated by interested amateurs and manufacturers. Every effort should be made to assure amateur radio votes at the ITU.



A Modern QST

The club magazine would interest many more amateurs if it were written in a warmer and more friendly tone. It would look more like 1970 with modern type and better layout design. Readers might have more confidence in the League if both sides of controversial problems were openly discussed in QST. Some of the departments which fill up so much of the space in QST could be shortened or eliminated in the interests of bringing information of interest to the most readers.

Directors Meetings

The inability of management to get decisions from the directors more than once a year has

(cont. on p. 102)

Last Chance for SAROC Flight!

From early indications, the upcoming "fun" convention in Las Vegas (January 1971) will be the biggest success of any ham convention ever held anywhere – bar none. If you've got a vacation coming, or if you would just like to take the wife and get away for a weekend, by all means attend! Even if your wife doesn't like conventions, she'll want to go to this one – because Las Vegas is a magicland – probably the only place in the world where you routinely bump into TV personalities, movie stars, and other famous personages. (Last year I poked Don Rickles with a Motorola telescoping antenna.)

If you're planning a West Coast vacation anyway, here's your chance to be really sneaky. You can fly on one of SAROC's two chartered "champagne" planes (from New York or Chicago), stay a full 3-night weekend at the Flamingo, enjoy a couple of stage shows, and buddy it up with hams from everywhere – all for less than conventional airline rates.

As if that weren't enough, additional free "flings" are being sponsored by public-spirited groups and organizations. For example, Ham Radio magazine is footing the bill for an all-you-can-drink cocktail party on Thursday night; the next evening, Swan Electronics is picking up the tab for the same kind of arrangement. And the FM boys in Las Vegas are planning a head-busting three-night open house, with free hard, soft, and hot stuff to drink.

The round-trip "everything included" plane fare from New York is $229 (from Chicago, it's $199), and there's a full-page ad in this issue that tells exactly all that the price includes. But the ad doesn't tell you that SAROC is *the* Western convention, where the accent is on fun and the emphasis is on ham radio. This January will mark the Sixth Annual Radio Operators Convention and the fourth (and by far the biggest and best) national FM convention.

With the August FM lineup (practically all the big names in repeaters) and the unprecedented current popularity of VHF FM, a turnout of more than a thousand FM'ers is expected. This, coupled with the already well established popularity of the other aspects of SAROC, should make it a convention to top all others in ham history.

If you're going, better make plans now. If you don't reserve a seat on one of the charter flights before November 25, you'll have to get there under your own steam – and that could get expensive.

Discrimination. . .

Wayne Green used to mention occasionally that the League wouldn't let him speak at this convention or that – that the League wouldn't let him set up a booth for 73 at various League-sponsored affairs, and other seemingly unfriendly or discriminatory actions on the part of the ARRL. To be quite blunt, I only half-believed him because his charges all seemed to be so fantastic.

But at the recent Boston convention, I found out for myself. I was invited to speak on repeaters, and accepted. But the League said no. I saw a letter Huntoon had written saying that I wasn't fit to speak at any League convention.

A few of the fellows protested to the League, even to the extent of offering mild threats of "breaking off" with ARRL affiliation. But Robert York Chapman, New England Division's director, answered one of the protestors with a counterthreat. It is never too late, he said, for the League to back out of backing the convention. Clearly, the convention planners had to make a choice between the League and the staff of 73.

Working almost surreptitiously, but closely with the convention planners, 73 rented an auditorium in the hotel where the convention was being staged, then held its own programs with its own speakers. And the whole thing went off extremely well.

The next convention was Tarrytown, another League-sponsored affair taking place within the Hudson division. I suggested to Wayne that we set up a booth there.

"Go ahead and try," Wayne told me. "But I can tell you now that they'll tell you their booth space has already been sold out."

Well, I tried anyway. I contacted Harry Dannals, who told me in a very friendly and congenial manner that there would never be any space for 73 in any convention that he is involved with.

Now, fellow readers, I have just told you the truth. There is not one ounce of exaggeration in the foregoing. And if Harry Dannals is an honest man, he will certainly admit that what transpired between us was exactly as I have related.

I charge Harry Dannals with discriminatory practices, and I charge the ARRL with sanctioning such practices. I don't want to make an enemy of Dannals, because, quite frankly, he is a personable and congenial fellow. But he must learn that his acts are not those of a responsible director.

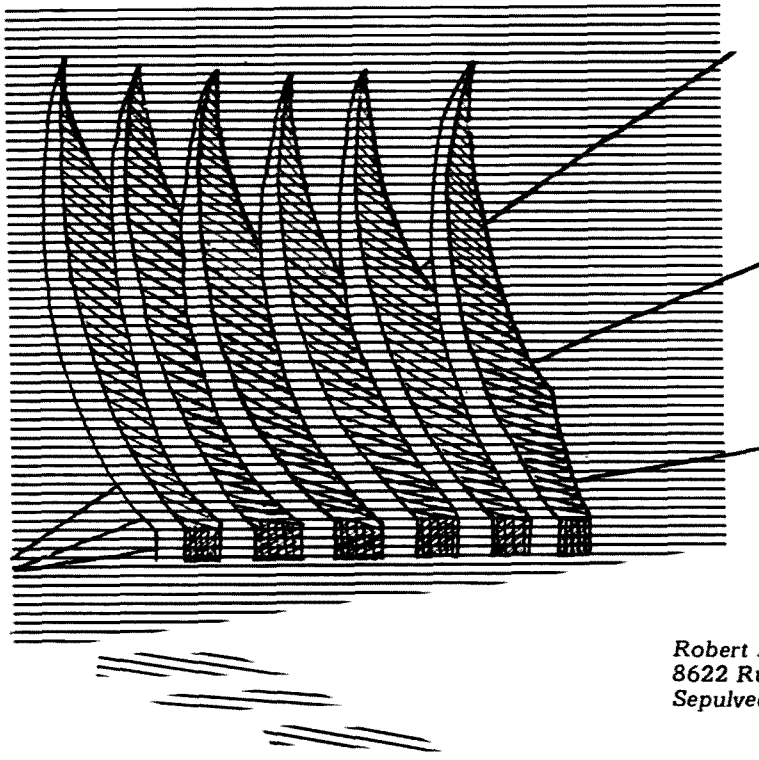
Those of you in the Hudson division who agree with me could probably carry a great deal of weight if you'd drop Harry a line letting him know how you feel.

. . .K6MVH/1■

Ed. Note:
Last month (or the month before), Raving Dave took on the Technicians in the country, and after three rounds went down for the count. This month, as "Dave the Brave," it's Conditionals. Watch for his subsequent attacks on Novices, premarital sex, Mexican food, the electoral college, and motherhood.

In previous issues I have mentioned phone patches, usually Latin-American in origin, which have been QRM'ing the DX frequencies, especially the low end of the 20 meter phone band, in ever growing numbers. The response of the readership has not been particularly encouraging; there seems to be a feeling that nothing can be done about the situation because, in the words of one of my correspondents, ". . .foreign operations cannot be regulated or controlled." While this is partially true, let me assure you that it is not completely impossible to effect changes. There is no basis for the total frustration which has been expressed.

There are certain actions which can be taken that may prove to be effective; for example, a large percentage of these patches are being run by stations in Florida and Puerto Rico, both of which are indeed subject to the regulations of our own licensing authority. The FCC – while many U.S. hams may consider it unsympathetic to the needs and desires of the amateur fraternity – is quite responsive and sensitive to reasonable requests, *when they are made in a responsible and constructive manner.* It is far from an impossibility to envision the establishment of an officially designated frequency allocation which would limit the patches to sequestered portions, as is presently done with RTTY, thus going a long way toward eliminating the annoyance.



But there is another side to this coin. The phone patch stations are also entitled to a fair measure of consideration. There is no foundation, either in the regulations or by operating precedent, for DX'ers to feel that they are entitled to a preemptive "lock" on those portions of the bands which they regard as desirable, and that they are perforce within their rights in bludgeoning the opposition into submission by their sheer weight of numbers, by using power amplifiers, extravagant antenna systems, or by any other means. There is still a right and wrong, after all.

The problem is a knotty one. Both groups have raised legitimate complaints. Both have valid grievances. And somewhere along the line, accommodations must be found so as to create order out of chaos.

A tangential point is being raised by the General class operators. Many DX stations seem to restrict their listening frequencies solely to our U.S. Advanced and Extra class subbands, making it virtually impossible for the Generals to compete for DX on an equitable basis. Of course, it must be acknowledged that it is awfully simple for anyone to master the relatively elementary material covered in the single examination element which upgrades them to the Advanced class. Anyone who is at all serious about working DX would be more than willing to devote a small portion of his time toward accomplishing this simple task.

The Conditional class ham, however, is faced with a genuine crisis. He must qualify in all elements, both CW and theory . . .is given absolutely no credit for any elements in any of the exams . . .hence must pass the 13 wpm code test plus the General and Advanced theory elements. Many of us are prone to forget that there are vast numbers of people who hold this grade. If you will examine the figures (they may be found in recent issues of the callbook), you will learn that of the total ham population, more than 10% fall into this category. There are 10 states in which Conditionals outnumber Generals! In a few of these states the examination points are truly beyond a reasonably convenient traveling radius. But in several of the states referred to, this is not the case, and I fear that the Conditional ticket has been acquired under terms which could not be regarded as completely justified by the circumstances. The regulations have been applied, in all too many instances, to circumvent the qualifying requirements, and some persons who could easily be expected to get to the examination points have simply exaggerated the hardship angle of the physical infirmity excuse. I am personally acquainted with several self-styled "invalids" who eat like horses, work like mules, and climb up and over ridges like mountain goats during the deer

(cont. on p. 104)

SOLID STATE EXCITER

Robert E. Bloom W6YUY
8622 Rubio Avenue
Sepulveda CA 91343

My original thoughts about undertaking a design project of this magnitude were brought about through a challenge by W6EGZ, after having just completed a three-year design of a solid-state receiver. This was early in 1966. Based upon the complexity of the receiver it was anticipated that about one year would be required to complete the transmitter. This would mean using all available evenings and weekends, abandoning all on-the-air operation and all other aspects of ham radio. As with the receiver, it took a similar three-year period.

The big hangup in progress was encountered in designing a satisfactory third-mixer stage, free of parasitics. I tried many mixer configurations initially without success.

It wasn't until the advent of a magical "black box" concept that appeared on the industrial electronic market, cloaked in secrecy and at a price of just under $200 that progress once again was under way. This started a frantic search for literature and information as to how this thing called a "double-balanced mixer" was operated. I say "magical" as this circuitry is so versatile that it can be used as a phase detector, frequency doubler, current-controlled attenuator, balanced modulator, pulse modulator, phase detector, etc. But let's start at the beginning.

Were it not for the availability of all commercial test equipment this project would not have been attempted. Such items as a Hewlett-Packard counter, generators, and meters; Tektronix oscilloscopes; Measurement Q meter and grid dip oscillators; temperature-controlled oven; sheet-metal cutting and bending equipment; and a Heliarc welder were some of the items used. For those who wish to duplicate all or part of this system, all pertinent dc and signal voltages are called out and all pertinent coil data can be found listed in Table I. All circuits other than the bulk elements of the power supply and the final are of modular construction; in today's technology of miniature construction this is the easiest and neatest, and lends itself readily to circuit change.

The individual circuits were first breadboarded, checked out, and then made into modules using single-sided 5/16 in. copper-

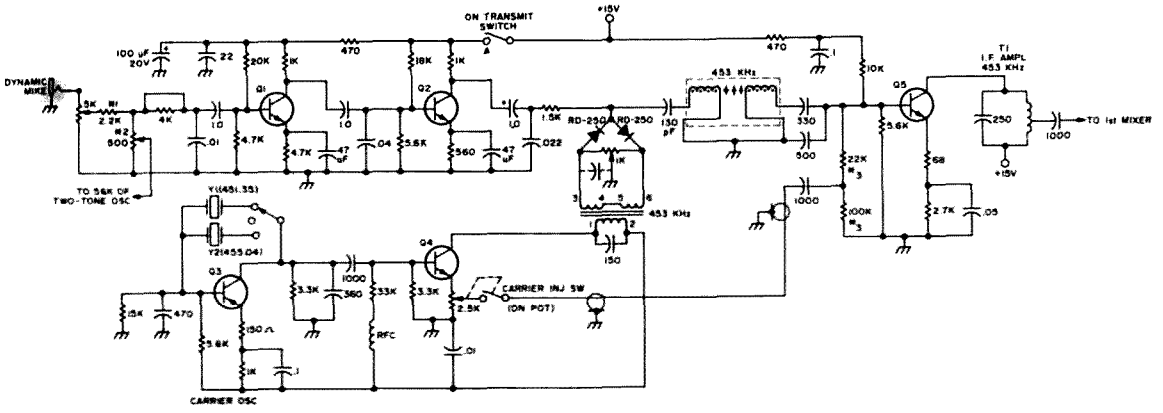
clad board. (Printed circuits could have been used; however, the construction about to be described was preferred as it lends itself to change where printed circuitry does not.)

It was first necessary to redraw the schematics, keeping all symbols to actual size and positioned exactly as they would appear on the finished board (according to the overall block diagram, Fig. 1). A dot



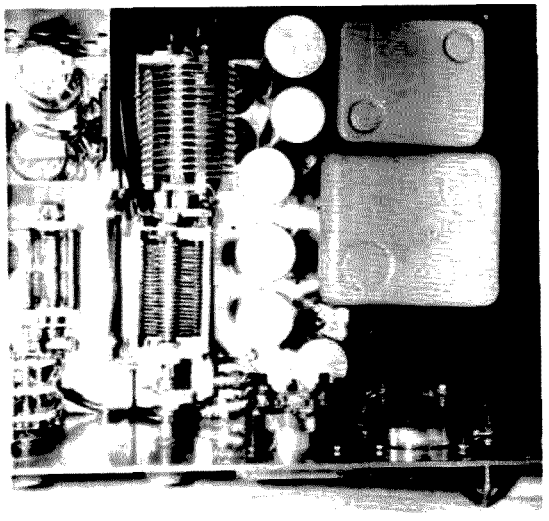


Fig. 3. Audio, balanced modulator, mechanical filter, i-f amplifier, carrier oscillator, and carrier buffer amplifier.

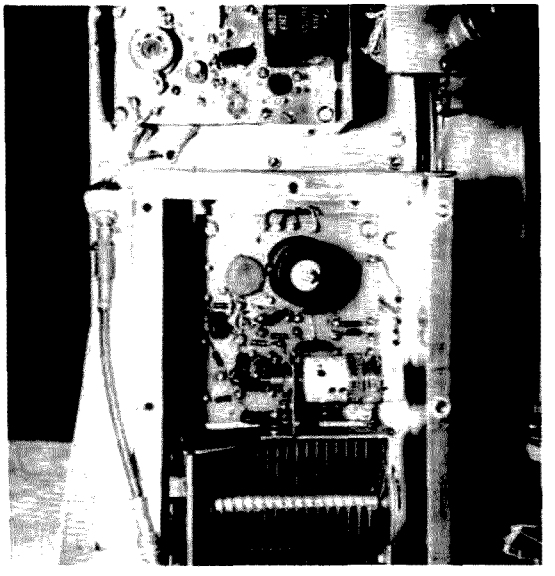
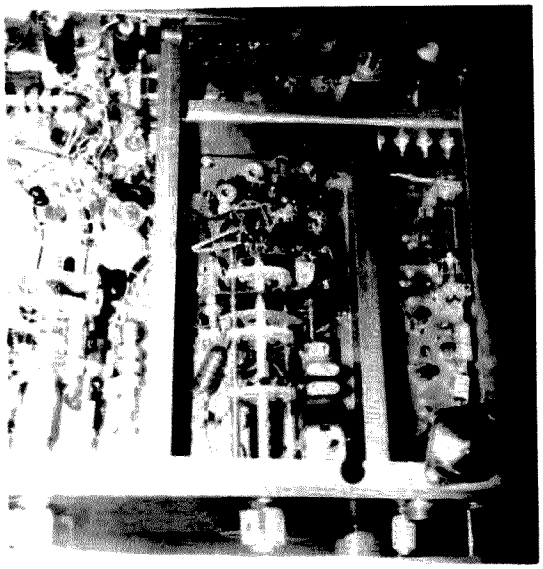
for linearity monitoring and testing. The mechanical filter is one of the higher quality Collins multi-element 3.1 kHz variety with steep skirts down to 90 dB. The input is series tuned while the output is series-parallel tuned using capacitors in a divider configuration. The loss introduced by the filter is only 9 dB and the gain of the following i-f amplifier had to be severely limited by tapping the coil of T1 near the bottom end and inserting degeneration in the emitter of Q5.



Overall gain measurements for this board were made using a 10/1 divider scope probe connected at the collector Q4 of the i-f amplifier. Using a single tone signal and no carrier, the 500Ω pot in the audio amplifier input circuit is set for a 2.5V p-p indication measured at the base of Q1. Inserting carrier to produce a 100% modulated sideband signal, the amplitude will increase to 4.8V p-p. Turning off the carrier and switching to a two-tone audio signal the indication will be 3.8V p-p.

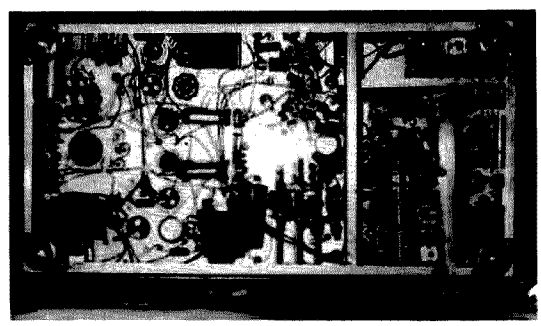
The next board, which is located in the lower left-hand corner on the bottom of the chassis, contains the 2045 kHz first mixer and 2.5 kHz crystal oscillator. The major problem encountered with this stage was in designing a mixer transformer, T2, with a Q high enough to reject the 2.5 kHz oscillator signal from its output. This was finally accomplished using the core material and data as furnished in Table I.



The 1.8 kΩ series resistor from the 453 kHz i-f to the base of the second mixer was selected to limit the signal to the mixer. With a two-tone signal, the mixer output amplitude at the collector of Q6 is 1.9V p-p. A voltage divider network consisting

Power supplies and complete final amplifier.

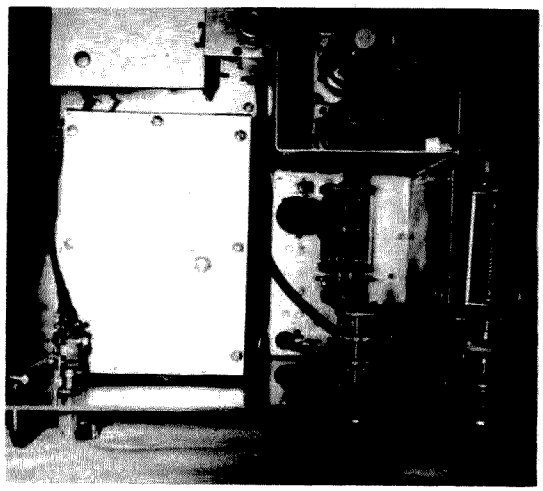
Vfo with lid removed; also shows selectable sideband crystals and balanced modulator.



Left — band select switch and 6146 sockets. Middle — band select crystal oscillators, 2nd and 3rd mixers, and rf amplifier. Right — Mike amplifier, mechanical filter, and i-f amplifier. Back — 2.5 MHz crystal oscillator and 1st mixer; two-tone oscillator.

of a 220 and a 150Ω resistor shunts the secondary of T2, setting the first mixer output signal level at 300 mV p-p. This measurement is made with transistor Q7 removed from its socket. A voltage dividing network optimizes the 2.5 kHz oscillator signal to the mixer T8, limiting the drive to 550 mV p-p. Both T2 and T8 coil data is critical and is listed in the coil data chart, Table I.

In the chassis compartment just to the right of the audio and 453 kHz board are a total of 3 modules. Toward the panel is the band selector crystal oscillator stages, Q14 and Q15. To the rear of the band selector is the broad band second mixer Q7 and emitter follower Q8. Mounted on top of this board is the third mixer, the double balanced mixer using the latest techniques, and the rf amplifier Q10.



The second mixer has a fixed frequency input of 2045 kHz and a vfo input of 2900–3550 kHz, making the usable output frequencies 4945–5595 kHz. The problem encountered here was to develop a coupling circuit with a flat response over 650 kHz. The coils were wound on ¼ in. ceramic slug tuned forms, resistive loaded to a Q of about 5. The coils are spaced ¾ in. on centers. The coupling capacitor value is very critical; the calculated value is 10 pF but in practice optimized out at 8pF. The circuit has a frequency response flat to better than 2 dB. Coil data can be found in Table I. Unloaded Q of each coil is about 55. The collector Q7 is tuned for the low frequency end of the bandpass while the emitter of Q8 is tuned for the high end.

T4 and T5 are wound on 4C4 ferrite toroids, 3/8 in. diameter. Ferrox cube 266T125 or equivalent may be used. I must have wound 40 coils of four different diameters and ½ doz. materials before coming up with a final design. Most of the materials tried seemed satisfactory except for the problem of driving their low input impedance. The key was to select a material with high enough permeability to obtain an input of something over 50Ω using a small number of turns and setting the emitter follower current to 10 or 15 mA. All of the information I received from engineering contacts advised designing both input and output coils with identical number of turns but I found this only to be true if a very wide frequency range was desired.

Bottom view of power supply and final amplifier.

My final design emerged with coils T4 and T5 with 13 and 9 turns respectively. These coils must be trifilar wound. It is recommended that the three lengths of 26-gage wire be of different color so that they may be easily identified. This is not an absolute necessity as identification can be made using a continuity meter. Twist the three lengths of wire around each other and then wind onto the toroid cores, spacing the turns evenly over the entire circumference and then tacking into place

Vfo, 12BY7 driver, 6146s, tuning capacitor for 3rd mixer and driver, and function switch.

using a small quantity of Polystyrene cement. Use the cement sparingly as the capacity effect is critical.

Actually, the mixer has a bandpass much wider than needed – possibly as great as 200 MHz – and should the cement spoil the higher frequency end, you will never know it as frequency interest ceases beyond 30 MHz.

The diodes used in the balanced mixer are Hewlett-Packard Schottky hot carrier type 2900. The type 2800 was found equally good. Experiments with 1N269, 1N270, and 1N277 types were found to operate satisfactorily in this frequency range also. The driving signal level into transformer T4 is 700 mV (p-p) and is measured using a two-tone audio signal source with no carrier inserted. Examination of the schematic for the balanced mixer and rf amplifier (Fig. 4) reveals many components, yet all are contained on a board 1¾ x 1½ in.

The only other circuits in this compartment are the band selector oscillator module and coil switch assembly. The rf coils are mounted on a metal disk-shape shield which is assembled as part of the bandswitch. (See ARRL sideband manual, page 66 for ideas on this subject.) Both the rf amplifier and the 12BY7 driver stages are panel-tuned by a miniature 8–108 pF two-gang capacitor. The tuning knob for this is located just to the left of center on the panel.

The function selector switch (Fig. 5) is also panel mounted. This allows selection of operate, zero-beat, CW, single-tone test, and two-tone test. The problem posed by the band selector stage (Fig. 6) was in obtaining an equal output amplitude from each crystal. This section had over three designs before the final one. This may not have been a problem at all if similar type crystals had been used but it turned out for the best since the selection of crystal types ceases to be critical. It is to be noted that for 80 and 20 meter operation the same 9 MHz crystal would be used. Although the final will tune from 80 through 10 meters, no coils were made for the rf amplifier and driver stages for the 80 meter band. Switch

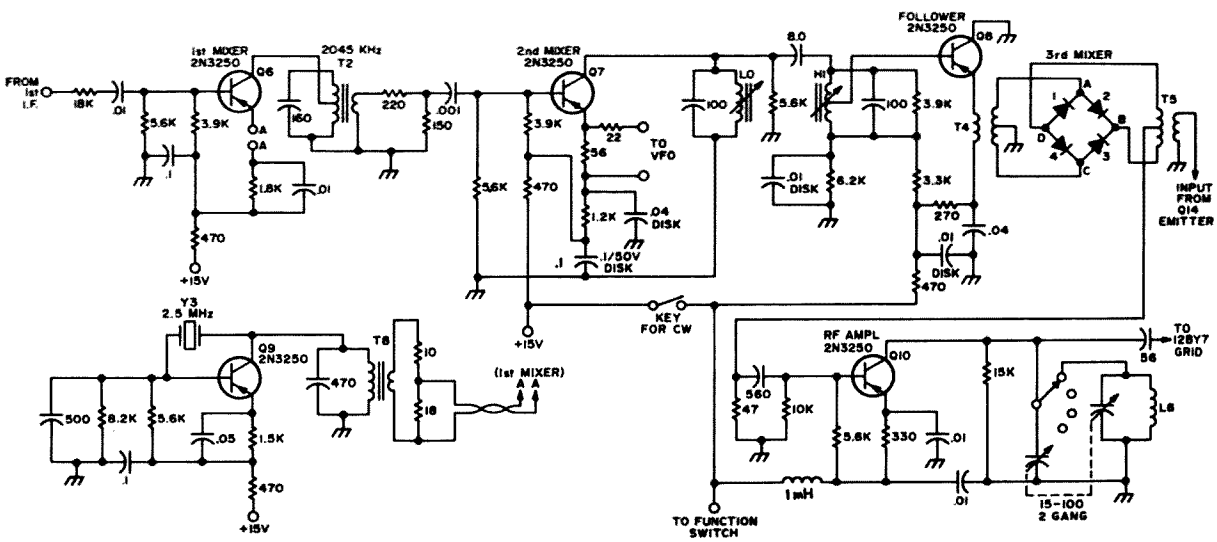


Fig. 4. Balanced mixer and rf amplifier.

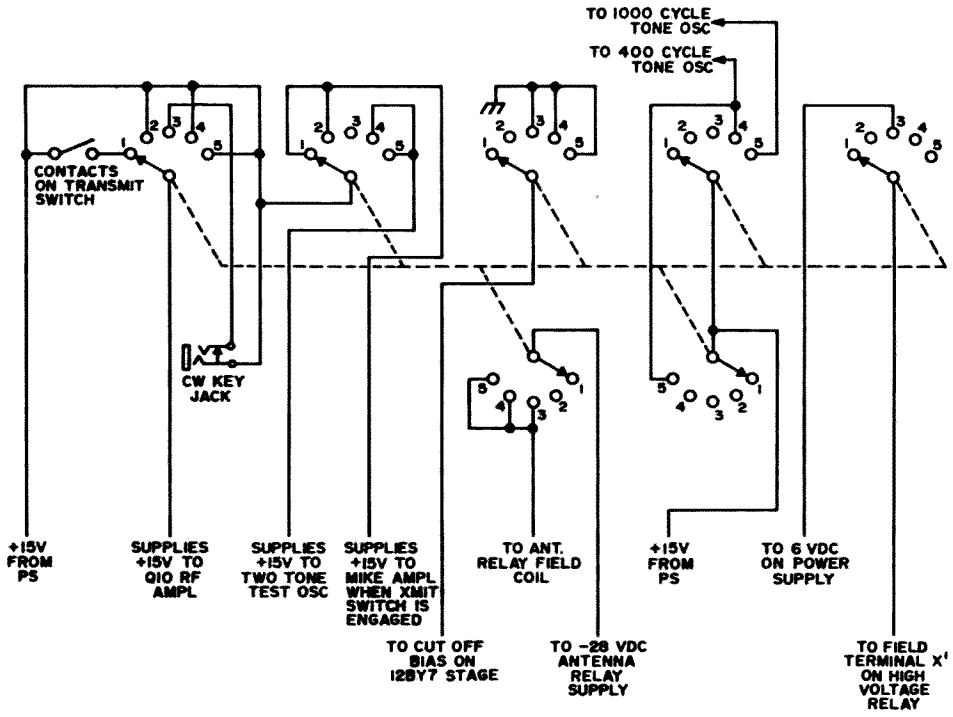

Fig. 5. Function switch.

positions are provided and 80 meter coils can be incorporated at a later date if desired.

Because of the 650 MHz maximum frequency coverage of the vfo it will require three crystals to completely cover the 10 meter band. A 23 MHz crystal covering 27.945–28.595, a 23.6 MHz crystal covering 28.545–29.195 and 24.2 MHz for 29.145–29.795. Other combinations can be used of course. In that these cannot be switched, one must decide what third of the band is desired at a time, changing crystals in order to move to any other third of the band. It would be possible to design a board and switching arrangement containing all crystals, making it possible to switch to any portion. My interests in this band do not go to this extent and I am satisfied to pick mine a third at a time.

The largest board on the bottom of the chassis is the one containing the mike amplifier, mechanical filter and i-f amplifier 6 x 1¾ in. Actually the entire exciter portion takes up only one third of the chassis space.

The vfo module is contained in its own shielded box and is located on top of the chassis and in front of the box containing the crystal carrier oscillator, buffer, and balanced modulator. Incidentally, these two modules were completed about a year before other modules of the transmitter, including construction of the basic chassis.

The vfo (Fig. 7) was designed using a tuning capacitor out of an ARC-5. As you know, this capacitor is considered as fine in quality and stability as any obtainable. The oscillator coil is wound on a ribbed ceramic form ¾ in. in diameter. The big problem with this stage was developing a pure sine

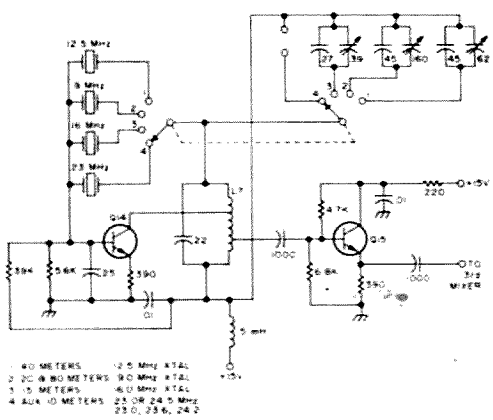

Fig. 6. Fixed crystal oscillator to third mixer (double-balanced mixer).

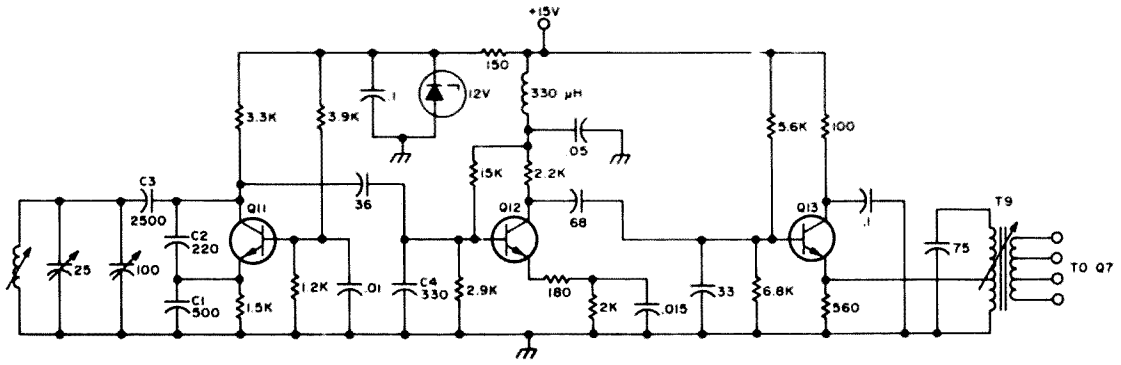

Fig. 7. Variable frequency oscillator (2.9–3.55 kHz).

wave (undistorted) rf output signal across the band. This was finally obtained after designing an amplifier (Q12) and emitter follower (Q13) that reduced the loading on the tunable oscillator.

An HP counter and temperature-controlled oven were used for the process of stabilizing the oscillator. Critical components are C1, C2, and C3. C1 and C3 are silver mica dogbones while C2 comprises four separate capacitors (2 ea. 68 pF N-750s, a 21 pF N-330, and a 63 pF NPO all in parallel). Looking back over my data, the temperature tests were run for over two weeks. Frequency drift is 11 Hz for a change of 25°F over the vfo frequency range of 2.9–3.5 kHz. Once this module was completed, the unit was closed completely and not opened again until pictures were recently taken of the entire transmitter. At that time, only the top cover was removed.

At the time this unit was designed I did not know what output voltage would be required to drive the second mixer as plans for this stage were still quite a way down the road. Hence, a multitapped coil with output from 1.0 to 2.5V p-p was made. This turned out to be a bad guess as the output from the lowest tap was more than optimum. Rather than go back and redesign the coil (T9), a 22Ω series resistor to the emitter of Q7 was incorporated, thus optimizing the second mixer for the best output waveshape. It is suggested that anyone duplicating this design use a secondary winding on the 3/8 in. diameter ceramic slug-tuned T9 form of 12 turns tapped at 4 and 8 turns, rather than the information as given in the coil table. No series resistor is needed if this winding data is used.

The two-tone oscillator (Fig. 8) is located in the same compartment with the 2.5 MHz oscillator and buffer module and is mounted to the back side of the chassis in a vertical position.

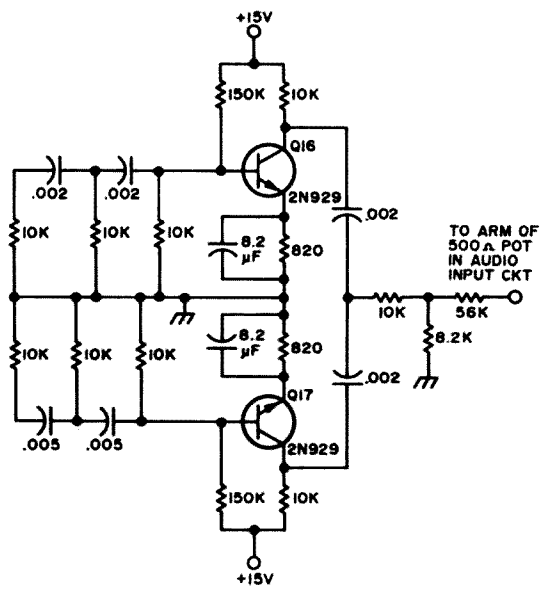

Fig. 8. Two-tone oscillator schematic.

The vswr indicator circuit was constructed so that all components could be mounted in the space below the rf tuning capacitor. The right-hand portion of the chassis contains the regulated power supplies (Fig. 9). A module containing all of the rectifier diodes as well as the complete

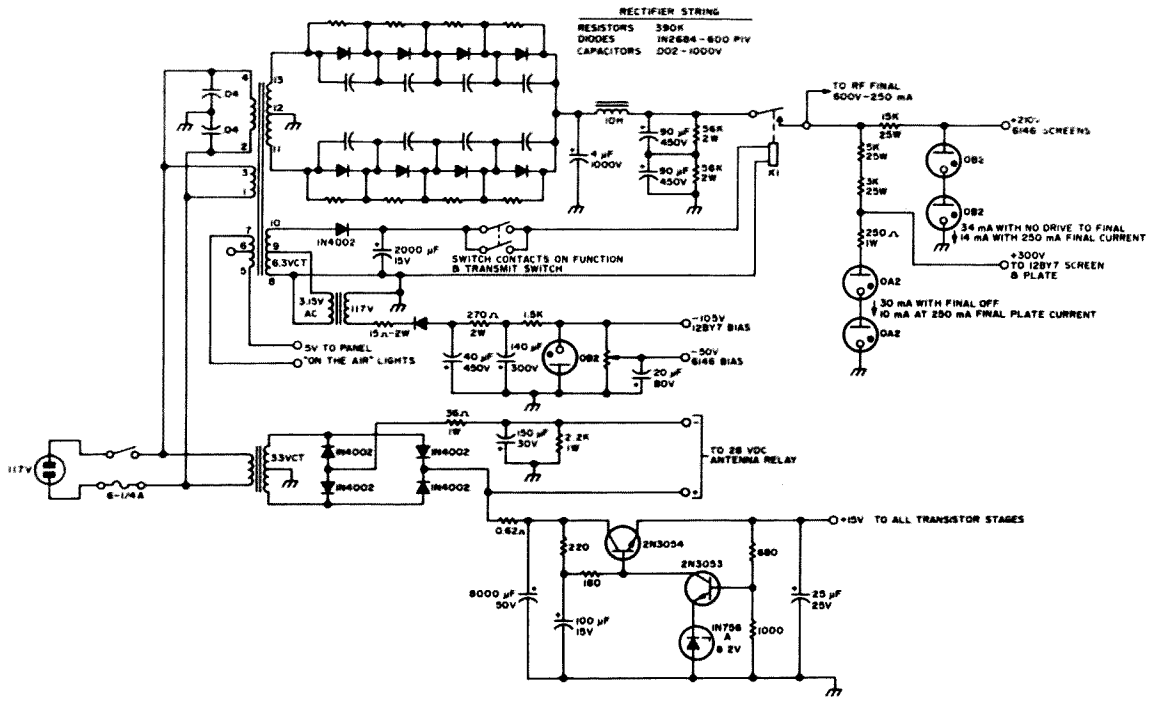

Fig. 9. Power supplies for SSB transmitter.

component circuitry for the low-voltage and antenna relay supply mounts on the side of the chassis.

The high-voltage transformer is hermetically sealed, containing three centertapped secondary windings. The 6.3V winding serves three functions: furnishes the 6.3V needed for tube heaters, it operates the high-voltage relay, and it furnishes 3.15V primary power to operate a separate transformer for the bias supply. The high-voltage rectifier string is made up of 8 1N2684, 600 PIV diodes, each shunted with 390 kΩ resistors and 0.002 mF (1 kV) capacitors for transient suppression.

The ac. line switch has a configuration that turns on the low voltage dc supply in its center position and adds line power to the high-voltage supply in its up position. The function switch is a three-deck, five-position, seven-circuit affair made up from an Oak switch kit.

Function Selector

Function positions are as follows; Sideband, tune, CW, single-tone, and two-tone. Positions 1 and 2 are similar except that in position 1 there is no supply voltage on the third mixer until the transmit switch is activated. In position 2, voltage is supplied to the mixer and by inserting carrier; the vfo can be set to zero beat in the receiver at the desired frequency. This condition is not desired on position 1 as it may interfere with the reception of the station being worked.

In the CW position, voltage is removed from the audio stages, and B+ is supplied to the driver and final. The telegraph key interrupts B+ to both the second and third mixers as well as the transistor rf amplifier stages. Positions 4 and 5 provide voltage to one or both of the tone generators, respectively.

The transmit switch is the multileaved telephone switchboard type, and in the transmit mode controls the following: cuts the bias voltage to the 12BY7 driver, energizes the high-voltage and antenna relays, supplies voltage to the audio amplifier and third mixer, and switches the *standby* and *on the air* panel lights.

Solid-State Control for SSB Exciters

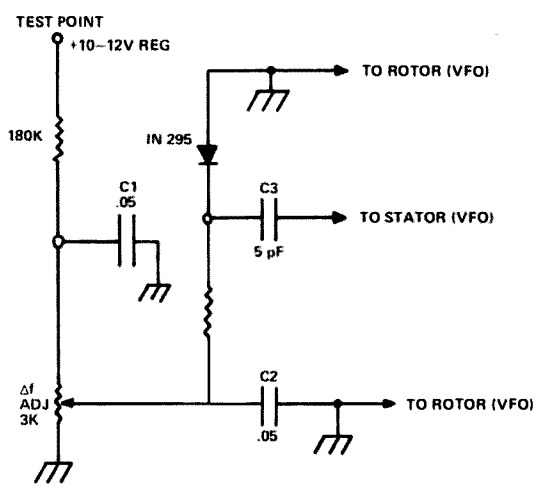
E. Dustin W4NVK
571 Orange Ave W
Melbourne FL 32901

The conventional approach to solving the critical problem of tuning a sideband receiver is to use lots of bandspread and a very good mechanical knob linkage to give very fine tuning adjustment capability with little backlash. Sometimes, though, even the best knobs get jerky and develop some backlash after a hundred hours use or so. The only difference between very good knobs and not-so-good knobs is the amount of this jerkiness.

To forever remove this backlash problem and give you a degree of tuning fineness such as no mechanical dial can approach, you need only add a simple diode variable capacitor for precision frequency shifting, or "delta frequency" control.

The best amount of delta frequency ($\triangle f$) for amateur use appears to lie between 200 and 400 Hz. The fellows with separate transmit and receive controls have an awful time staying on frequency in a roundtable, and I frequently have to shift the full 400 Hz from the operating frequency to reach the worst of them. This control is especially necessary to tune in a feminine voice, since the exactness of tuning SSB gets very critical as the voice pitch gets higher. I have never been able to get clear reception on female ops with my mechanical dial, but with the vernier $\triangle f$ there is one critical frequency where their voices clear up noticeably.

This control is a must for the serious phone-patch operator, too, since hams who develop a facility for understanding a highly garbled SSB voice forget that the layman does not have this tolerance, and can't understand even a slightly garbled voice. In receiving an off-tune patch, they will be polite, but they may be, in reality, missing much of it.



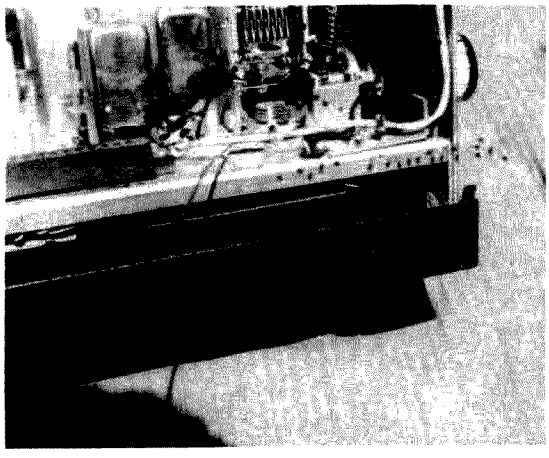


Fig. 1. Schematic diagram of "delta frequency" vernier control for SSB receivers.

This critical nature of SSB has to do with the harmonics and overtones of the voice, all being shifted the same number of hertz instead of being shifted the same percentage of frequency. You who have tape recorders are probably aware of the fact that the voice doesn't appear to suffer much if the tape speed is slightly wrong, although music does protest some. With the same degree of error in frequencies, applied as a frequency offset (which is the same number of hertz regardless of frequency), even voices become seriously garbled, and music comes out as total nonsense. If you doubt how critical this is, try to tune in music on one of the foreign BC stations with your sound just right until you get zero frequency error and the proper phase, within about 90 degrees of the station carrier. Even with this vernier control, you won't find it easy to tune to music, since a phase-lock receiver and residual carrier must be used to get phone company quality out of SSB.

The circuit for the $\triangle f$ control is shown in Fig. 1. As indicated, the only adjustment device added to the existing receiver is the tuning pot, which can be mounted anywhere you please. A shielded line of a three-wire twisted line can feed it. Since only dc is present on these lines, their length is of no consequence. However, this is a moderately high impedance circuit of up to about 3 kΩ, so keep the pot leads

The entire circuit can be placed neatly within the existing space of most transceivers. This photo shows the components mounted near the vfo capacitor in a Galaxy.

away from ac lines or you might induce enough ac to FM your vfo a small amount.

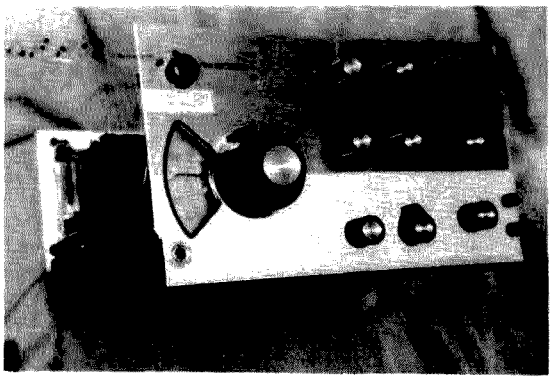
Placement of parts is not critical, but keep the components attached to the vfo tuning capacitor rigid, or the whole thing will be microphonic. Keeping reasonably short leads on the components will accomplish this objective just fine.

The pot I used was a used 3 kΩ TV pot. I drilled a 3/8 in. hole in the front panel, and mounted it as shown in the photo. Whatever pot you decide to use, make the hole in the panel far enough away from the calibrated dial to keep the pot from rubbing the dial after it's installed. A small diameter pot makes things a lot easier.

Tuneup Procedure

Before connecting capacitor C3 to the vfo stator, tune in a carrier and zero-beat the signal on your SSB receiver. Use your crystal calibrator if it is of the 100 kHz marker type, or use a commercial BC station that is easily *identifiable*. Pick a low vfo frequency so that your vfo tuning capacitor is almost completely meshed. This minimizes the frequency shift when you connect C3. Set the 3 kΩ pot to its center of range and connect the free end of capacitor C3 to the stator of the vfo tuning capacitor. The carrier that was zero-beat will shift frequency as you do this because you just *added* a couple pF capacitance in parallel with the vfo tuning capacitor. You will have to *remove* an equal amount from the trimmer on the vfo to bring back the zero-beat on the same carrier you had before. (Be careful not to zero-beat another carrier!)

To remove the capacitance, unmesh the vfo trimmer just enough to zero-beat the carrier like it was before you attached C3.



That's all there is to it; your vfo is now back in perfect alignment, and you will be able to shift the frequency up and down about 300 Hz with the pot.

Diodes to Use

I used a 1N925 TV video detector diode, but just about any type will work. Since we are only using a couple of picofarads of the diode in parallel with 30 pF or more of vfo tuning capacitance, it matters little whether the diode is a low-Q computer diode, a detector diode, or a high-Q varicap. If the diode you use doesn't give you enough shift, just reduce the value of R2 some (not below 10 kΩ, though) or increase the value of C3 (not above about 10 pF).

This $\triangle f$ control shifts both transmitter and receiver frequencies; therefore, in a roundtable discussion, if you tune off to hear a station, go back to the original pot setting before transmitting. If the other fellow has a transceiver, leave the pot where you hear him best, since this automatically makes him hear you best also.

More elaborate circuits can be designed which automatically return your vfo to the center range of the pot when you transmit, by using a contact on your transmit relay and putting a fixed bias on the diode when you transmit. The desirability of this is questionable, however. With this circuit, simplicity is foremost, and in a regular QSO, you just adjust the pot to hear the other party and leave it.

If you don't mind boring a small hole in the face of your transceiver you are sure to find a handy spot for the adjustment shaft. This one was placed in the upper left corner, right above the vfo dial.

Should you tremble at the thought of poking a hole in your "store-bought" rig, bring the pot wires out to a little handy box, so you can remove every trace of your modification later if you desire. I personally would pay more for a used rig with this control, but to each his own. You can also calibrate the pot in hertz if you have a calibrated af generator to compare its shift with.

HAMS are a FuNnY BuNcH of PEoPle!

Al Brogdon, K3KMO
RFD 1 Box 390A
State College PA 16801

Hams are a funny bunch of people. They will work for days with their beam antenna orientation to make sure it is pointed to within one-half degree of the indicated direction – never considering the fact that the beamwidth of the antenna is 40 degrees.

They will overload their transmitters by factors of 50% or more, and milk that last watt out of it – when it takes a power increase of four times to make one S-unit difference.

They will stay out of a ham club and complain until the cows come home about how poorly it is run. But they never want to join and work to straighten out the club's problems.

They will spend five hours and more a day building and installing ham equipment, telling the wife all the while that they just don't have time to put a new line cord on her iron.

Some of them will crank their final amplifiers up a little and run 3 kW PEP, never thinking about the fact that they would have to run more than 5 kW to make a significant difference in signal strength above 2 kW PEP. A few of these hams have time to think this over during their license suspension period.

They will spend hours every day talking with people all over the world, but never say hello to their next door neighbor.

They will tell their wives they can't afford a new chair for the living room while they are writing out the order for a new $700 mobile installation.

They will buy surplus equipment to save money, and then spend an amount of money on it's conversion that would have bought good commercial gear that would have done the same job better.

They will set up stations with which they could communicate their ideas, but they they will give a signal report, a brief weather report, a description of their station, and run out of things to talk about.

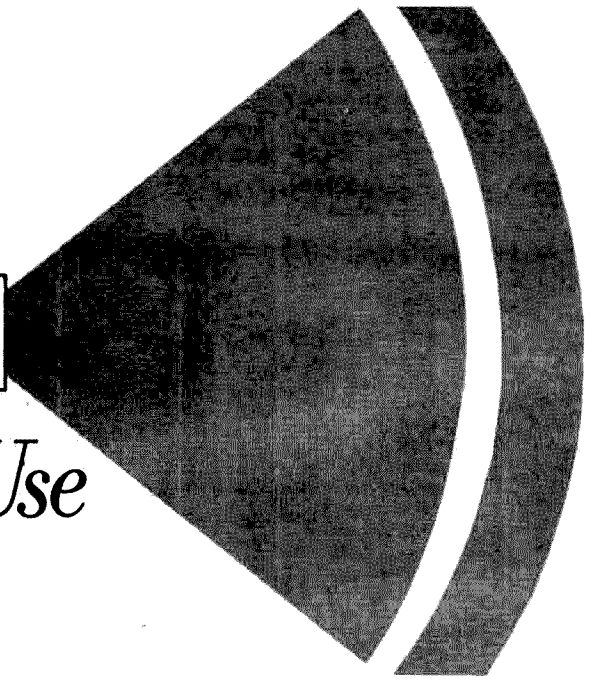
They will spend an entire 48-hour contest period at the rig, leaving it only to catch short naps and take care of necessary bodily functions, but during the week they can't spare 10 minutes of their time to play with their kids.

They will buy complex and expensive electronic keyers so the extra dots and dashes their sloppy keying causes will be well-formed and correctly spaced.

They use Q signals on voice, and then have to use phonetics to get the letters across, since voice is better suited for communicating words than for transmitting individual letters.

They will apply for every ham award they can qualify for to document their accomplishments, when many of the certificates are for a level of accomplishment roughly equivalent to being able to cross the street without getting run over.

They will load half a ton of amateur gear and antennas into the car and take off for Field Day, but then have to suspend operation halfway through the contest because the didn't bring a spare fuse.



They will take great pride in being a ham radio operator, and tell all their nonham friends of the many accomplishments of ham operators, and of the advances in the state of the art brought about by hams, when they themselves haven't been on the air in three years.

But one of the funniest things of all about hams is the typically human shortsightedness of most hams. They see all the faults of their fellow hams, and they are quick to criticize, but they are not aware of their own shortcomings. Aren't you glad that you and I aren't that way?

A 2M MINITRANSMITTER For Repeater Use

When an FM repeater finally came to San Diego last summer it was soon obvious that new possibilities and requirements were placed on 2 meter FM equipment. First of all, high transmitter power was no longer required nor desirable. In many cases output power in the milliwatt level was adequate to activate the repeater since it is virtually line-of-sight to most parts of the county. Also, high power on 146.34 MHz would cause interference with Los Angeles area remote stations that are similarly located on high mountaintops. This would add further strain to already delicate relations with the Los Angeles groups who can (and do) jam San Diego just as easily.*

Secondly, a large number of RCA CPCR2D pocket receivers had become available for portable use, but the transmitters available with them were not transistorized and the batteries were heavy and expensive. With this arrangement, and with the repeater, it became possible to have full use of the repeater while walking around on the ground in most parts of the area. This is probably the most fascinating part of repeater operation, approaching the science-fiction TV shows by being able to talk to someone a hundred miles or more away while walking around on the streets of a city with a hand-held transceiver. However, the idea of having to carry tubes and batteries while doing this was still quite revolting. Solid-state transceivers are becoming available, but are still in the $250 to $350 price range. In view of this, it was finally decided to continue work on a solid-state transmitter. This article describes the first successful results of that project.

* Ed. Note: Author is making reference to L.A.'s R.O.B.I.N. (Remotes Operated By Insociable Nets) problem.

Design

Figure 1 shows the schematic of the transmitter as it is now. The most significant part is the oscillator, which offers maximum simplicity and reliability. The crystal frequency is 18.29250 MHz, and is multiplied eight times to get the 146.34 output frequency. Amateur designs of about a year ago used oscillator frequencies in the 8 MHz or lower range. With the sloppy interstage selectivity as used in this transmitter, lower frequency crystals cause more spurious multiples because they are closer together in frequency. With a crystal frequency of 18.0 MHz, the multiples will be at least 18 MHz apart, and it is easier for the tuned circuits to select the proper multiple and reject others. A Motorola varicap is used to modulate the oscillator. With an audio input of about 22.5V

peak-to-peak (maximum bias on the diode from the power supply), the deviation is a little more than the 5 kHz at the output frequency. Two varicaps might be used in parallel if more deviation is desired – if it doesn't lower the frequency too much to compensate by lowering other capacitances.

A few notes about the crystal should be made: The crystal must be a "fundamental" cut to work in this circuit. An overtone crystal will oscillate on its fundamental frequency, and will be different

the transistors increases at lower frequencies, it is possible to have low-frequency feedback paths that have been overlooked while concentrating on the VHF circuitry.

Using the coil in each stage for the dc return to the collector not only simplifies design, but provides a low-impedance collector return for lower frequencies that would not be possible if choke-and-capacitor coupling were used.

The final transistor can be driven to as much as 2W dc input in this circuit, but was held to one watt to reduce heat

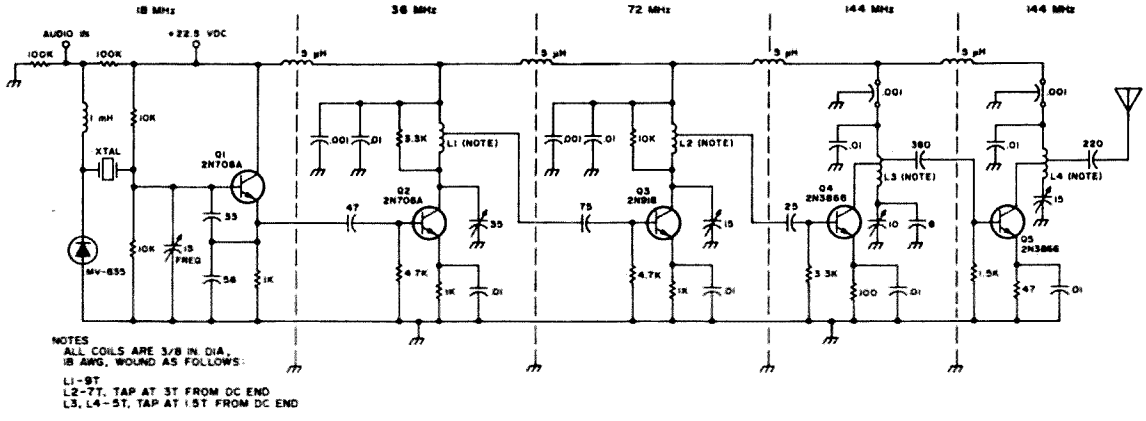

Fig. 1. Schematic.

from its marked frequency. The crystal load capacitance in this circuit is about 20 pF and this should be noted in the crystal order. A general-purpose type crystal (0.01% error) might be satisfactory, but a commercial-standard 0.001% crystal was ordered by mail, and quickly tweaked down on frequency with the 15 pF trimmer.

The three stages following the oscillator are all conventional common-emitter, LC-coupled doublers. While operating, they are driven into class C. Interstage matching is accomplished by trial-and-error tapping of the coils.

The use of ordinary resistors in the base bias circuit was found to be most successful. This avoids the resonance problems when chokes are used, and probably helps stability by lowering circuit Q. Large capacitance (0.01 μF) bypass capacitors were used to minimize the chances of low-frequency oscillation. Since the gain of

dissipation problems and battery requirements. Power can be adjusted by changing the value of the emitter resistors in the multiplier stages, and changing interstage coupling. (Ed. Note: This unit can be used to drive the DyComm 15W FM power amplifier described in 73 review, September 1970.)

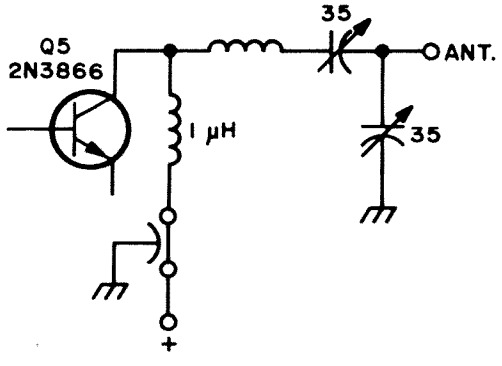

Fig. 2. Alternate Output Circuit. L can be five or six turns 3/8 inch diameter, #18 wire. Try to make it work.

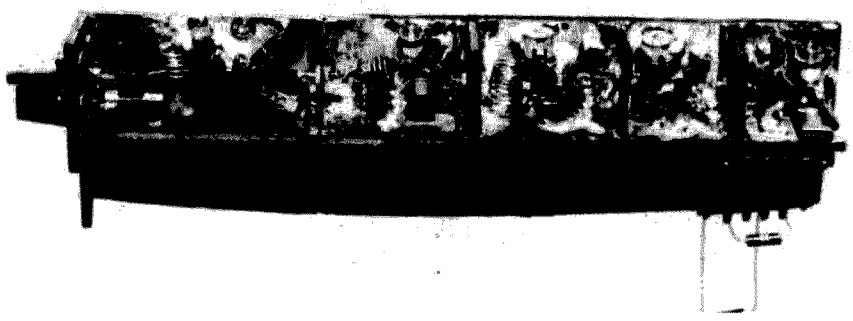
A more popular output tuned circuit is included in Fig. 2, but it was not tried in the transmitter because the circuit used in Fig. 1 was considered satisfactory.

Construction and Tuning



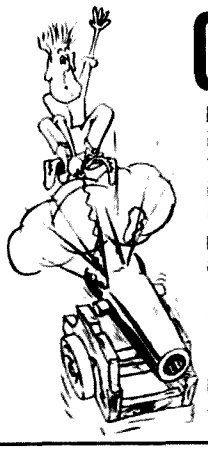
Simply having a schematic available does not mean that it will be easy to build a transmitter. Construction is very simple, but making it work will occupy the majority of the time. Since all transistors are different and any two transistors with the same number can have widely different impedance and gain parameters, the tuned and coupling circuits will require extensive adjustment. Many of the values in the schematic will probably be a little different in different transmitters.

Considerable experience as well as appropriate test equipment is required for the tuning and tweaking. A grid dip oscillator is a must, and a general-coverage receiver that can cover all the frequencies between the oscillator and final output is always handy. An swr bridge or power meter that works at VHF is necessary for tuning for output power, as well as all the other tools and test equipment that are usually available in the average shack.

his own pet methods and parts available to work with. As a final resort, industrial parts catalogs will list all the components necessary.

Speaking of parts, half-watt resistors can be used, but quarter-watt resistors will be easier to work with because of size. In the case of the driver and final emitter resistors, power considerations will necessitate the use of half-watt resistors. Small dipped mica capacitors are used for interstage coupling. Other than the feedthrough bypasses, disc ceramic capacitors were used for bypassing. Indeed they are not the best, but seemed to work in this case. Just make sure that all parts are as small as possible. JFD makes good ceramic bypass capacitors as well as small disk variable capacitors. The crystal holder is the HC-18/U type and is soldered into the circuit.

The transmitter should be built one stage at a time, starting with the oscillator. Each stage should be checked and tuned as it is built. The oscillator will be easy because there is nothing to tune but frequency adjustments and the circuit is very easy to get working. Check for output while listening to a receiver tuned to the



Photograph of the complete minitransmitter strip. Note how stages are shielded into "compartments."

The circuit was laid out on a double clad printed circuit board that makes a very simple arrangement. Small Teflon standoffs were glued to the board with epoxy to provide a place to solder the transistors. Details of the construction and parts to be used will mostly be left to the individual builder. Anyone who would build this transmitter probably would have

crystal frequency. Adjust the two resistors that provide the bias to the varicap to put the diode voltage at about 10V measured at the diode–crystal connection with a VTVM or oscilloscope.

An audio signal voltage can be applied at the "audio in" point in the schematic. Make sure that the audio source is isolated with a series capacitor to prevent affecting

These are packed by slave labor (to cut costs) so please ignore notes calling for help, etc. that may be slipped into the bundles. **73 Gunsmoke, Peterborough NH 03458.** Send cash, check or negotiable securities.

the diode bias. A maximum of about 20V peak-to-peak can be applied here. A preassembled imported audio amplifier can be used for modulation, or an amplifier can be built to fit individual requirements. If the amplifier is designed for driving a speaker, a transformer may be necessary to step up the output voltage. It should be possible to detect FM from the oscillator by listening to a general-coverage AM receiver and slope-detecting the signal.

Tuning the multiplier stages can be accomplished by measuring the emitter voltage of the following stage while tuning the preceding one. Voltage across the emitter resistor measures emitter current, which is a measure of rf drive. To determine that the stage is operating class C, compare the emitter and base voltage, as measured with a VOM. The emitter should show more voltage than the base. The base never really has more bias voltage than the emitter, but when the VOM probe touches the base, it partially shorts out the rf there and reduces or eliminates drive. Since the emitter is bypassed, measuring emitter voltage has no effect on the rf drive. A grid dip meter must be used for the final tuning to be sure that the state is operating on the right frequency, and to check for parasitics.

The resistors across the coils in the schematic were used as a cure for parasitic oscillations. The stage should be built without the resistor first, and then resistors can be added when instability occurs. A grid dip meter can be used to detect parasitics and oscillation, but an AM general-coverage receiver is much more sensitive.

Adjusting the output stages is just a matter of changing taps on the coils while watching for transistor overheating, checking for parasitics and oscillation, and retuning each time for resonance. Also be sure to check that the right harmonic is being tuned for on the grid dip meter used as a wavemeter.

Leave a TV set turned on; it will let you know when oscillation breaks out and give a little entertainment while you're working. Watch channel eight; the 36 MHz signal tends to come through the 72 MHz doubler, and multiply five times in the 144 MHz doubler to cause TVI on channel eight. This has been the major source of TVI after the transmitter was operating properly. A 36 MHz series-tuned trap might be used at the collector of Q3 as a last resort, but with proper tuning this should not be necessary.

The final results will take a considerable amount of time depending on the intuition or "feel" that the builder has for what is happening in the circuit.

Conclusions

This transmitter has provided good results in the final analysis, but there are problems and changes that could be worked out. The thing is quite difficult to tune and clean up, and some kind of standard chassis, housing, shield, board, or whatever should be designed to provide ease of mechanical construction and duplication, rf shielding, and mechanical strength. Double-tuned, inductively coupled interstage circuits might be used to provide better selectivity. Tapped iron slugs are available, but I haven't located a source. Supposedly, this would be much less expensive than using the ceramic variable capacitors, and much smaller.

Other variations of this same theme might include a low-power 100 mW version for short range use with an absolute minimum of size and power consumption. Be creative.

RECEIVER OFFSET TUNING FOR THE HW 100

Want transceiver offset tuning without costing a cent? Without altering your rig? Give this a try:

The introduction of the transceiver to ham radio has brought many advantages. But the one disadvantage that will force a fellow *not* to select a transceiver is its inability to follow the drift of a CW signal without altering the output frequency. This separation of frequencies was realized by a very simple method which can be employed in many other rigs. It has two good things going for it: no modification and no money required.

Theory

The theory behind this method of offset tuning is simple when you recall some of the laws we all knew to get our ticket (and then promptly forgot as they were of no *practical* value). Inductive coupling is the first order. This is the method by which we will get the change into the rig without altering or soldering. This method will allow you to introduce a change in the frequency of the main vfo. You'll also want to be able to remove the change at will, as on transmit. Figure 1 shows that the inductive coupling links the main vfo with the added tuned circuit. It is with this outboard tuned circuit that we can change the received frequency. The capacitance of the variable capacitor should be *low*. Try and keep it in the area of the tuning capacitor of the vfo. In my rig, the HW-100, this is 63 pF, so anything near that will do. The vfo coil in my rig is 5 μH so I kept the inductor of the remote circuit as near to this as possible. None of the values are too critical as to demand adherence to strict values. By keeping close to the values of your rig you will have better tracking and zero beating of the received CW signal. And you'll know that when the remote tuner is switched out of the circuit you are still near enough to be hearing the same signal you were listening to on the offset tuning. The greater the change in the offset tuning circuit values, then the greater the coverage up and down frequency from the zero beat. I felt that in CW a great range of offset tuning was not of any use and it also would make tuning more difficult. I just about use the full rotation of my capacitor and keep within the passband of my rig, the tuning rate is slow enough that I can move it around in the 400 Hz CW filter I have added to my HW-100. It is this simple remote tunable circuit that allows the offset tuning.

Construction and Circuit

The variable capacitor I used is a BC tuning variable with only the rear section in use. If you have any old variable in the

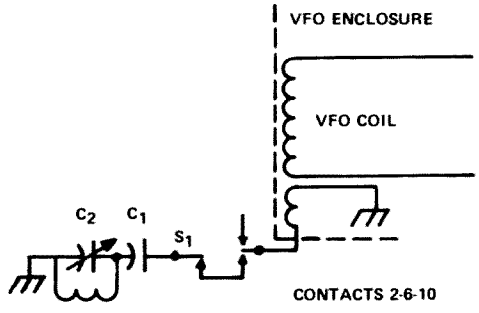

Fig. 1

junkbox, then that's the one you use. I reduced the high capacitance of this section by putting a 100 pF Mylar capacitor in series with it. (You can fool around with values until you get what goes best with your rig.)

The coil for the remote tuner was made after looking in the ARRL handbook; I found that a 1½ in. long coil by ½ in. wide (36 turns per inch) would give me close to 5 μH, which is good enough. The coil was made by winding 24-gage magnet wire, enameled, around one of those fat pencils used for advertising gags. The size of the wire is not important just so you can get about 36 turns to the inch on a half-inch diameter.

If you have spent any money up to this point you need a new junkbox. Now for the hookup.

The vfo of the HW-100 is removed according to the Heath manual instructions. Reference will be made to my HW-100, but any transceiver that allows you to get at the vfo and its coil can be used with this offset tuner. The vfo is turned bottom-side-up so the inside of the enclosure is accessible. Be careful not to damage the screened dial. One end of the pickup wire has its insulation scraped away and it is soldered to ground on the inside of the vfo, as close to the coil as you can manage. This is the only soldering and modification to the rig. In my rig, the ground for the coax feedthrough into the vfo was used as ground. With tension on the ground connection, make one full turn around the vfo coil and while still keeping tension bring the wire to the nearest spade bolt. Wrap the hookup wire around the bolt 2 or 3 times, just for anchorage. Make these turns just at the base of the spade bolt where it meets the edge of the vfo enclosure and tuck the turns down into the little space between the shaft portion of the spade bolt and the edge of the enclosure.

By tucking the turns of wire into these spaces you will keep them from being cut or grounded by compression from the edge of the vfo enclosure when it is remounted and the nuts tightened. It is most important that the turn of wire around the vfo coil stay in place without the least movement. Movement of any kind no matter how slight, even from vibration, can alter your received signal a few hertz up or down the band. A drop of some kind of glue will do the job of keeping the wire turn in place.

Remount the vfo as directed in the Heath manual. Make sure the remaining free end of wire is not caught under the edge of the vfo and is outside the vfo enclosure. The wire is now fed to S1, from S1 to C1, to rotor of C2, then to ground from C2.

If automatic switching is desired, place RL1 contacts 2-6-10 before S1. The homebrew coil is placed across the variable capacitor to ground, placing it in parallel with C2. Keep all leads as short as possible. This completes the wiring of the remote offset tuner.

Alignment

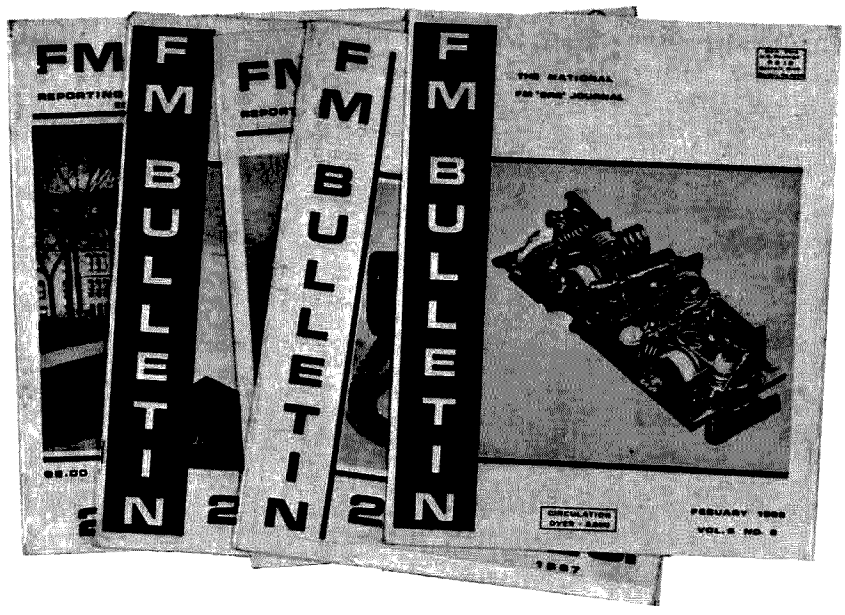
The transceiver must now be adjusted only because the loop of wire around the vfo coil has moved the vfo frequency and it will not be the same as the readout frequency of the dial. This alignment is simple because the *vfo is not adjusted*. This is the part that can be frustrating at first because you do not know where the frequency has shifted to. I found the turn of wire dropped my vfo down 30 kHz. This meant nothing had changed as far as function of my vfo except that there now was a 30 kHz shift down the band. This was corrected by "slipping" the dial on the rig until the frequency coming from my vfo and the readout frequency on my dial were the same. I used CHU, 7335 kHz, as my locating frequency. I used this instead of my signal generator only because my transceiver receives CHU (and besides, I was too lazy to set up my signal generator). Any method of obtaining a locating frequency is fine.

For alignment with the offset tuner in the circuit, tune in a CW signal on any band with the offset tuner out of the circuit. I found RTTY signals to be of longer duration and more dependable. Adjust the vfo for the highest meter reading of the locator signal. Place the

variable capacitor of the offset tuner in the fully unmeshed position. Put the offset tuner into operation by closing S1. When S1 is closed you should still receive the same locator signal if your capacitor and coil values are close to the values in your rig. One thing you may notice is a change in pitch of the locator signal due to a slight frequency shift (but don't worry about it). I am only interested in following the drift of a CW signal – not in how much frequency spectrum my offset tuner ranges over or in how many hertz the CW signal drifts. (Though this can be done if you care to take the time to calibrate for it.)

Adjust the variable capacitor so that when the remote tuner is removed from the circuit by S1, the pitch (frequency) will be close to the pitch of the signal from the rig alone. What you will be doing here is getting a zero beat for the offset tuner against the rig. Try to get this position of the offset tuner as close as you can to the rig's signal. Mark this zero beat position on the variable so you can return to it at any time. Now when you're receiving and the offset is placed at zero beat you can tune up or down frequency as a CW signal drifts. I found that my zero beat on the offset did not change from band to band. It would appear that alignment for one band takes care of all the bands. This completes the adjustment and alignment of offset tuner and the transceiver.

Placement



My offset tuner at present is outboard. It can be mounted in the HW-100 without making holes in the front panel. The screws in the upper right and left corners of the front panel are replaced by the variable capacitor and the on–off switch (S1). The components in this case will have to be of the miniature type to use the holes as they are now. To use what comes out of the junkbox, in my case, meant enlarging the holes. But I think this is one case where modification will add to the worth of a rig and should not be a deterring factor. The shame of it all would be spending money for miniature parts after having come this far for free.

The Little GATE DIPPER

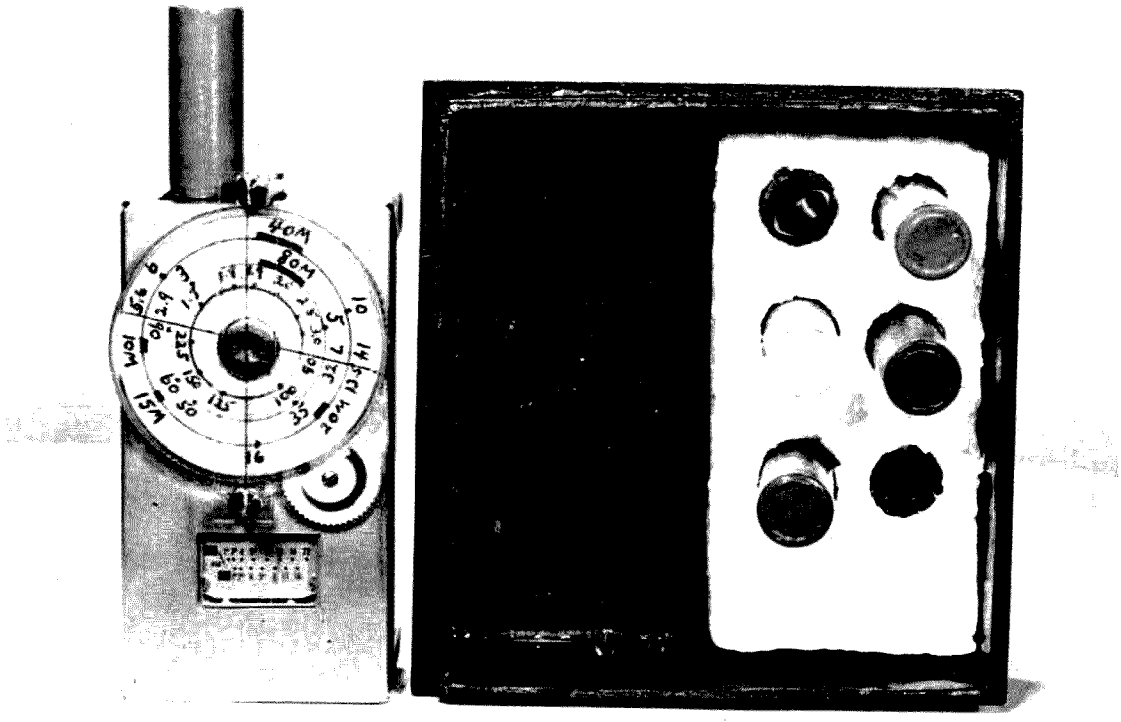
John Aggers W5ETT
1509 Desoto
Ponco City OK 74601

Covering 1.7–225 MHz, it is simple, inexpensive, and easy to build.

Possibly you now own a grid dipper, but is it small, easy to handle, and cordless, making it completely portable? If not, you will want to build this gate dip meter. The cost is extremely low – only about $7. All parts are readily obtainable and construction is simple. The plug-in coil forms, using battery plugs and polystyrene tubing, are easy to make.

The Circuit

An MPF 102 FET is used in a modified Colpitts circuit. Except for the #1 coil, where a choke is used, the B+ is fed to the centertap of the coil. This is necessary to obtain a fairly constant gate current as the oscillator is tuned to its end frequencies. Drain current varies from 4 to 1 mA proceeding from 225 to 1.7 MHz. At the same time the gate current varies from 20 to well over 50 μA.



From this, it is apparent that the stronger the oscillations the smaller the drain current and the larger the gate current. In gate dip operation, as power is drawn from the oscillator the drain current will increase and the gate current will decrease or dip.

Limited wavemeter operation, obtained by switching off the B+, is accompanied by a slight shift in calibration. When the circuit picks up rf, the FET suddenly goes into oscillation using the rf as its battery. Thus, the amount of rf picked up must be large enough or there will be no oscillation and no meter indication. However, despite these deficiencies, it is still considered a useful mode of operation and for that reason has been included. It is only necessary to wire the sensitivity control so that the resistance is maximum when the switch is in the off position.

Construction

A natural finish aluminum minibox (4 x 2-1/8 x 1-5/8 in.) is used for the meter case. The variable capacitor came from an old transistor radio and measured 1 3/8 x 1/2 x 1 in. The shaft was already squared and tapped for a small screw. Since those listed in the catalogs have a plain or flat shaft, you will have to use a collar with setscrew, or drill and tap the shaft. The trimmer capacitors are not used and should be removed.

To make the coil socket you will need three pin receptacles from an octal socket, two pieces of 1/8 in. Plexiglas approximately 7/8 x 3/4 in., and one battery plug for a pattern. The pins of the battery plug form a triangle. I shall refer to the holes at the base as the outside holes. Drill holes in one piece of plastic to match the pins of the battery plug. Match the two pieces of

The little gate dipper with spare coils.

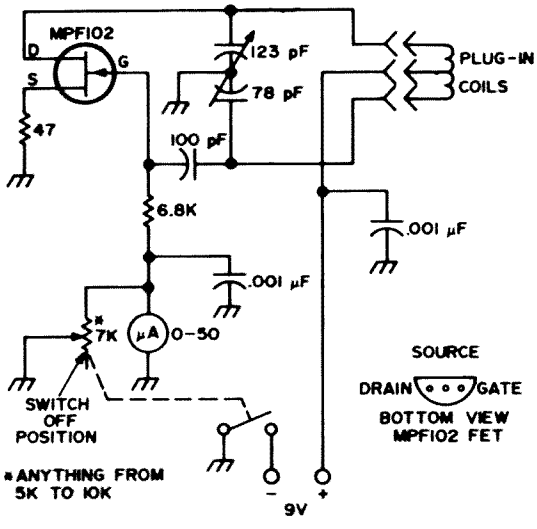


Fig. 1. Schematic diagram of the little gate dipper.

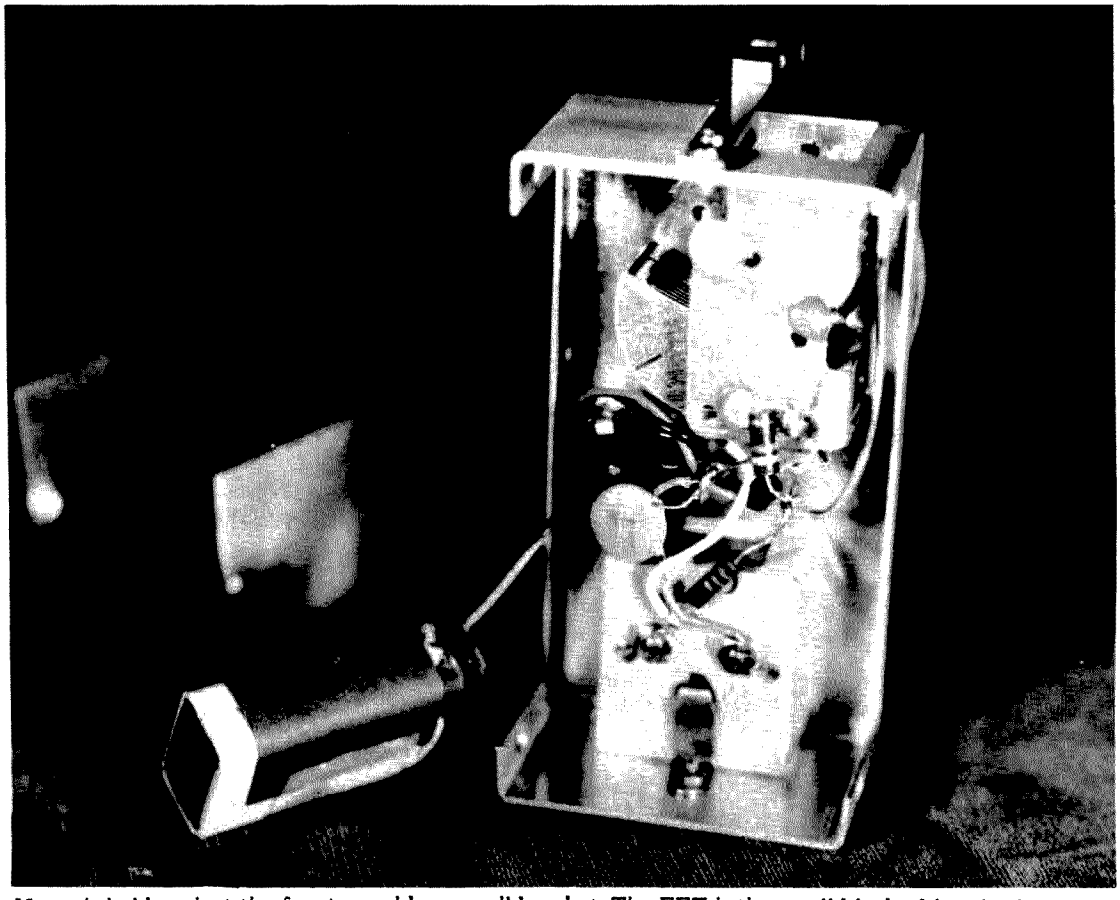
plastic, clamp in a vise, and drill the two outside holes in the second piece. Bend the lug part of each socket pin to a right angle. Slip one over each outside pin of the battery plug. Using this as a jig, solder the lug portions to the stators of the variable capacitor. Remove the plug, and the pieces of plastic should fit down over the variable capacitor. The lug part of the center socket pin is brought out between the two layers of plastic.

File a small notch in the bottom piece to accommodate the lug. Before cementing the two pieces together and to the frame, make each hole slightly larger than the diameter of the socket pins. This will allow for expansion when the plug is inserted.

The dial is made of 2-1/4 in. diameter 1/8 in. Plexiglas. To give the dial a rough edge, for good thumb traction, I heated an old gear wheel and rigged up an arrangement to rotate the dial against it. The gear should have rather coarse teeth and rotate with the dial, or you will create flat spots.

The variable capacitor can now be mounted in the case. Position it so that the top and sides of the dial will be just about even with the edges of the case.

The dial marker is mounted on square aluminum posts. The top post (2 in. long) has 1½ in. of its length filed down to a 1/8 in. thickness to reduce its bulky appearance. To make the hairline, scribe a line in a ½ in. wide piece of plastic and fill in with a ballpoint pen.



The sensitivity control I used was already prepared for the knob shown. If you don't have one like it, use a dime-size pot and a setscrew knob. Any resistance from 5 to 10 kΩ will be fine.

Keystone light meters are available from Olson Electronics in a package of five ($3.99) or Transistors Unlimited Co. (75¢ each). Some modification of the meter is necessary. Remove the light cell and series resistor. Drill two holes, spaced ½ in. apart in the back of the case to pass 4–40 machine screws for easy soldering, make sure the heads and nuts are clean and free of any nickel plating. The screws should be filed even with nuts in order to make room for the battery. Solder the leads from the meter movement to the terminals, but be quick because the plastic case tends to melt in a hurry.

Wiring is just a here-to-there proposition, requiring no terminal boards or terminal lugs. The FET is soldered in place supported by its own leads. With reasonable care you should not damage it. A battery holder was found unnecessary; however, it is a good idea to wrap a layer of tape or stiff fiber paper around the battery to prevent the metal case from shorting out the meter terminals.

Coil Construction

Figure 2 and the photo give the necessary dimensions and show the parts needed to make the coil forms. The battery plugs are listed in the catalogs to fit #482 and M3 batteries. The center pin should be filed slightly shorter to make the plug seat evenly in the socket. While you are at it, file the nickel plating from the ends of all plug prongs. This will make for easier soldering.

Meter is held against the front panel by a small bracket. The FET is the small black object in the center.

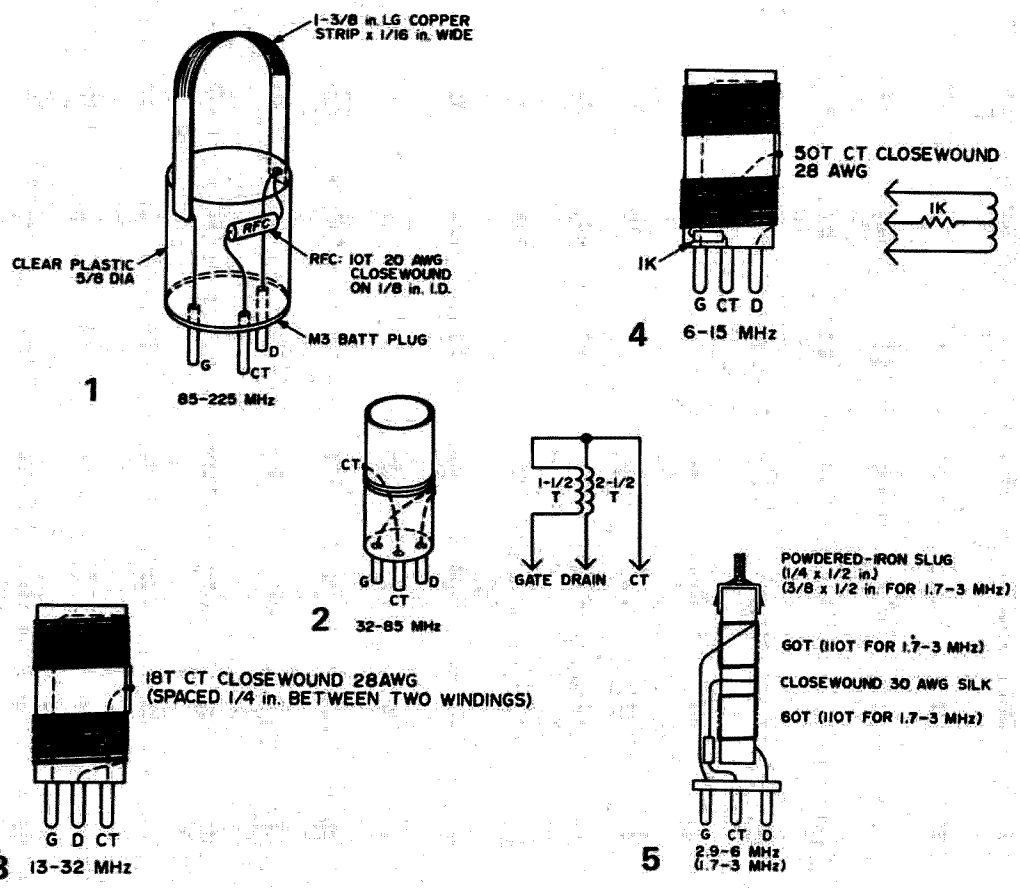


Fig. 2. Coil configurations for various frequencies of resonance.

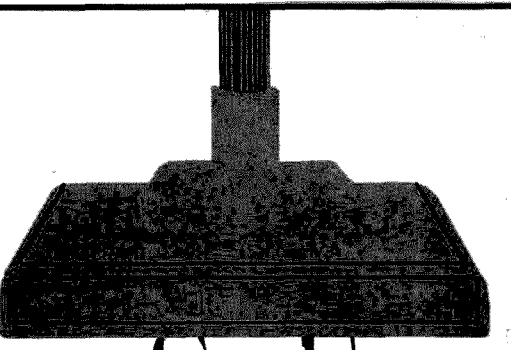
Complete coil information is given in Fig. 2. However a little explanation may be in order. The irregular method of winding the #2 coil is necessary to reach 85 MHz and still maintain oscillation. With 4 turns close-wound the highest was too low. With the 4 turns spaced, oscillation ceased at the highest frequency. The 30 AWG silk wire was taken from a TV flyback transformer. The resistors in the centertap of the last three coils improve the meter's sensitivity slightly. They are mounted right next to the coil winding. With a slight groove filed inside the insulating sleeve, it should slip over the resistor.

The #6 coil is layer-wound as space permits and scrambled wound the rest of the necessary turns. The top winding of all coils should end near the very edge of the coil form. This will make for easier coupling to a tuned circuit. After the coils are checked out the insulating sleeves may be glued to the plug base.

Allow the glue to dry for several days before plugging the open ends of each coil with a small cardboard disk. The coils are painted with colored lacquers. Colored paper between the coil and the insulating sleeve will probably work just as well.

Calibration



For calibration purposes, you will need another indicating oscillator or dip meter. Operate it in the diode or wavemeter mode and loosely coupled to the gate dipper. I calibrated only 5 points on each scale plus any ham bands which appeared. Remember the dipper is not a frequency meter but something to get you in the ballpark.

Conclusion

The little gate dipper was checked against a well known commercial tube equivalent and, as near as I could tell, they were just about even. The battery should last for a long time because the current drain is extremely low.

CLINKS IN A VACUUM

(A LOW PRESSURE ARTICLE FOR WIVES)

My husband is a builder. No, he doesn't build coffee tables or bookshelves or breakfast nooks. Instead he builds important things like linear amplifiers, grid dippers, calibrators, and all those other things you need around the average American home.

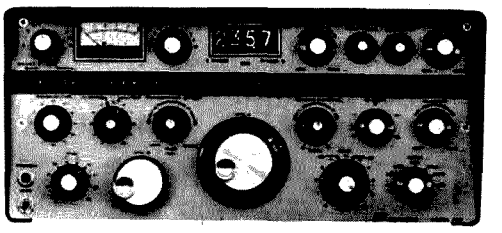
They say that Nature abhors a vacuum. Well, my husband does too. Most of the time I understand his drilling and pounding, his screams when he grabs the wrong end of a hot soldering iron, and the horrible whistle that wakes up the baby and indicates he is getting "zero beat." Our day of trial comes, however, when all too frequently it becomes necessary to vacuum the house.

We have a shaggy dog that sheds and you have to really keep after the clumps that surround him whenever he stops to scratch. This means toting out the vacuum nearly every day.

My part of the great vacuum debate comes when I start hearing the pings, clanks, and pows of "things" being sucked into my little vacuum's innards. It sounds disturbingly like bullets ricocheting among the rocks in a "B" western movie and it certainly can't be doing my vacuum any good. Investigation long ago showed these "things" to be various little pieces of plastic stripped off the ends of wires, bits of wire, melted glops of solder, small nuts and bolts, and other little indescribable things of Ham Husband origin. We have agreed that he should keep his activities confined to the spare room that is his "shack," but these things come out on his shoes, follow like a dust storm in his wake, and I think roll out by themselves in the night. Once, when I shoved a handful of "clinks" that I had gathered out of the vacuum bag under his nose, he peered at it, carefully picked out the little nuts and screws, and ran back to his shack mumbling something about precious hardware.

There is another side to the story to be sure. I usually just get the vacuum started and have suffered through the initial ten or twenty internal ricochets when he comes tearing out of that dark hole, often with headphones strung around his neck, striving to be heard over the combined noise of the vacuum motor and a sound like ball-bearing Ping Pong. After pulling the plug out of the wall (a move which someday may be fatal because he wired it himself), he finally gets across the point that my vacuum is making a horrible noise in his radio. I suppress the urge to ask him why he doesn't talk to this horrible noise just like he does to all the others and instead I ask the same question that I always ask him.

"Is there any way to cure our mutual noises without my giving up vacuuming and you giving up ham radio?" At the mention of the latter sacrilege he usually turns paler and retreats a few feet toward the comforting smell of burning solder. It is hard for him to turn any paler because the only sun he ever gets is when he works on antennas during the winter and at an occasional hamfest in the summer, but the burning solder smell is always around.



Normally then, we just stare at each other, both of us silently remembering the time he did try to do something about *his* noise. On that occasion he had grabbed up my vacuum and carried it off to his lair where he gutted it and added little round things to its insides with his ever-ready soldering iron. In a way he did temporarily solve both of our problems because when he plugged it in he blew the last fuse we had in the house. I wouldn't let him replace the fuse with a piece of solder, so he tramped out to the store muttering something about "ac working voltages."

I haven't let him touch my vacuum since, of course, but I ask him the same question each time just to bring him back to his senses. He usually is torn for a moment or two, contemplating an ocean of dog hair on the one hand and a normal life on the other. Remembering that dog hair gets into the fan on his linear amplifier, he usually compromises at this point and says, "QRX one . . ." I take the minute to pick up whatever bits and pieces and "things" I can see that he carried out with him on his last excursion. When I start vacuuming again after this mysterious ritual of "QRX" I know I'll be greeted by a sound worse than a trio of two-year-olds let loose to play with all the kitchen pots and pans.

All this that I have been telling you was true until just the other day. On that particular fateful day we had gone through our usual routine and I had asked him the usual question. This time to my amazement he said, "You know, sweetie, maybe you're right. I should spend more time with you instead of with my projects and radio. I could help you around the house. We could go out more, meet new people. I couldn't get much money for all that homebrew gear, but I could give it to somebody who could use it and then you wouldn't have any more clinks in your vacuum cleaner."

That day I was so happy! We closed the hamshack door and right then he started to help me around the house. The first thing he did to help was to shake out the rugs. The same eyes that can spot the latest transistor in a radio store window from a moving car at six hundred feet didn't see

Feature This

Signal/One's CX7 gives you

More performance than any transmitter/receiver combination

More convenience than any transceiver

More versatility

Compare the CX7 with any receiver for sensitivity, selectivity options, dynamic range, AGC merit, VFO smoothness, interference rejection.

Compare the CX7 with any transmitter for continuous power output in all modes, P.A. ruggedness, crisp audio punch, low distortion, instant CW break-in and spotting, quick band-change.

Compare the CX7 with any transceiver for total size and weight.

Consider the best at an amateur retail price of $2195.

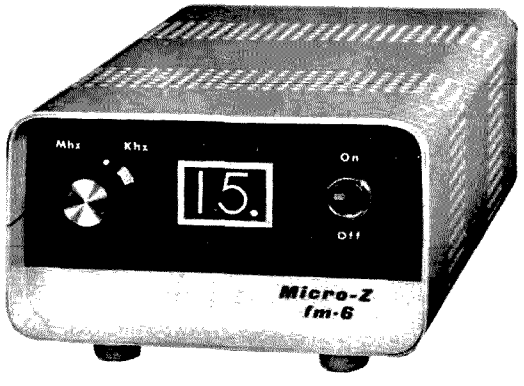
THE BEST
2 METER
CONVERTER

Model 407
$39.95
ppd.



144-146 MHz in. 28-30 MHz out
or 146-148 MHz with a second crystal
Available at $4.95 each.

A full description of this fantastic converter would fill this page, but you can take our word for it (or those of thousands of satisfied users) that it's the best. The reason is simple—we use three RCA dual gate MOSFETs, one bipolar, and 3 diodes in the best circuit ever. Still not convinced?Then send for our free catalog and get the full description, plus photos and even the schematic.
Can't wait?Then send us a postal money order for $39.95 and we'll rush the 407 out to you. NOTE: The Model 407 is also available in any frequency combination up to 450 MHz (some at higher prices) as listed in our catalog.

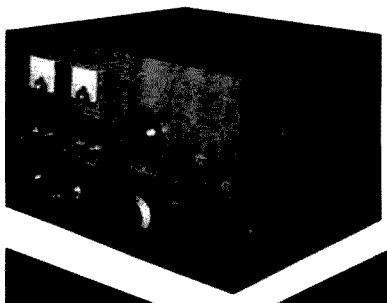
Micro-Z Co.

Box 2426 Rolling Hills, Calif. 90274

my hand washables hanging on the line upwind, but he was helping! The second thing he did to help was to put the dark things in the washer for me. He even included the skirt to my dark wool suit which was in the pile going to the cleaners. He said he wanted to make a full load.

That night we got a babysitter and went out to dinner. He paid ten dollars for our steak dinner, and then my reformed husband suggested that we go somewhere else for an after-dinner drink. Dazzled by all the attention, I happily agreed. We had just gotten settled with our dollar-fifty after-dinner drinks when who should pass by but his old high school girlfriend and her heavy-handed, shifty-eyed husband.



After we had paid the babysitter her ransom and my husband was taking her home, I began to think. "It would be nice to have help with the housework, but the experience might take years off my life. What would he do when he found that doing chores together really isn't much fun? Would he go to the bar with the boys and maybe run into that floozie without her heavy-handed husband? The ham friends that come over now are really quite polite, even when they are loaded down with all that stuff they carry in and out. At least now he's around if I need him. That smile on his face when he shows me his latest contraption does bring a lot of joy into the house . . ."

The next day we agreed that we should go into the hamshack together and start to clean it out. It was just by chance, of course, that I bumped against the receiver and turned it on. When that station came on calling CQ I was only curious when I asked, "Can he hear you as well as you hear him?" It was with a great deal of pleasure that I saw his eyes flash with an inner determination not to weaken, which died when flooded out by the desire to get just one more signal report.

The smell of burning solder fills the air around our house. The clinks in the vacuum cleaner are still there, but somehow they mean something different to me now than before. They mean I have a ham at home that loves me.

YOUR SECOND LINEAR

After building a grounded-grid linear using four 811As and modifying it, improving it, etc., I decided to build a linear that would perhaps reflect some of the knowledge and experience I had learned.

Much thought was given to what type of tube or tubes would be used. The new 3-500Z was chosen for several reasons. First, a tube requiring plate voltages in the 2–3 kV range was to be desired to keep the plate tuning capacitor to a reasonable size (250 pF). Secondly, a tube with a large plate dissipation was wanted to give a much larger margin of safety than was available with the 811As. The 3-500Z has a plate dissipation of almost twice that of four 811As. Third, the low output capacitance of the 3-500Z enables it to be used at higher frequencies much easier. Fourth, the 3-500Z efficiency range makes it very versatile. Output ranges from 750W out with 1.1 kW input at 3 kV to 500W out with 800W input at 2 kV. And finally, the intermodulation products are very low with the 3-500Z as with other zero-bias triodes designed for grounded-grid class B service. Here is a table showing typical operation of the 3-500Z.

Dc plate voltage	3.0	2.5	2.0	kV
Zero sig. pl. current	160	130	95	mA
single tone pl. current	370	400	400	mA
single tone grid cur.	115	120	130	mA
PEP input power	1110	1000	800	W
PEP useful output pwr	750	600	500	W
Resonant load imped	5000	3450	2750	Ω
Cathode input imped	115	100	100	Ω
Intermodulation prod.	−30	−33	−38 (3rd order)	dB

The schematic diagram of the amplifier (Fig. 1) is pretty much self-explanatory and there is not very much new about the design. It follows what is in the handbook and other publications. A high-capacitance tuned input circuit was used to obtain greatest linearity. Without the tuned input circuit the exciter sees a low load impedance over part of the rf cycle and a very high impedance over the remainder of the cycle. Consequently, the waveform suffers. Also with an untuned input the rf plate current return path to the cathode must travel the outside shield of the coax to the exciter plate circuit and then back the center conductor to the cathode. This can result in high intermodulation distortion. With the tuned input circuit these problems are solved as the tank circuit provides

Inside the 3-500Z linear amplifier.

a "flywheel effect" for good waveform and a short rf return to the cathode.

Many of the components used were obtained from suppliers advertising in 73. Relay K1 in the rf section is included to enable the linear to be switched in and out of the circuit with the plate voltage switch S2.

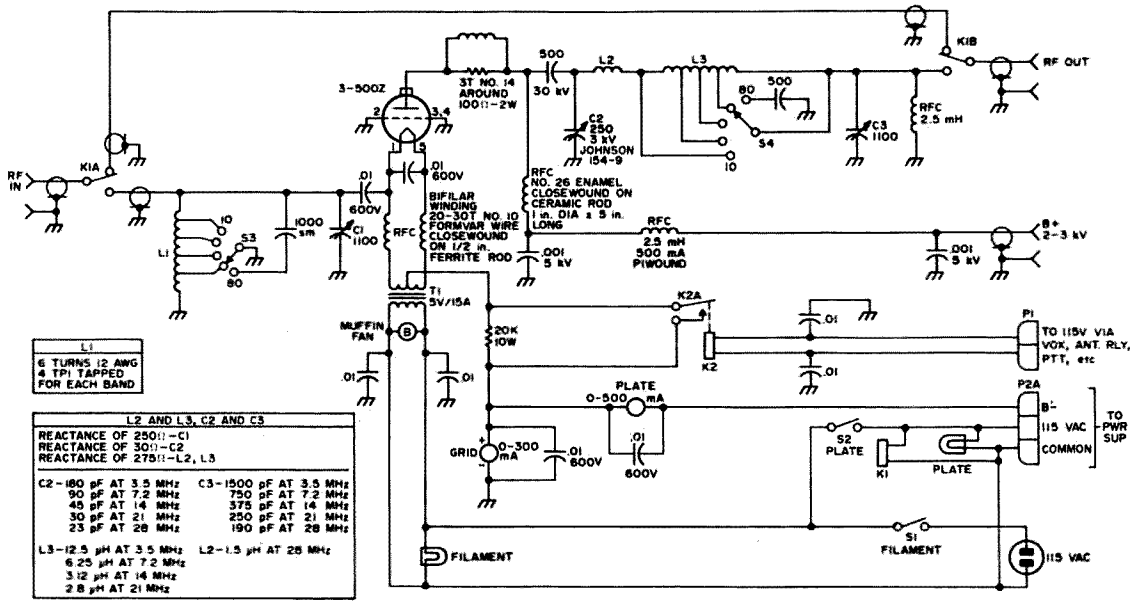

Fig. 1. Schematic of the 3-500Z linear amplifier. Coil data is shown on the table insert.

Tube Socket

The tube socket is home-made. I cut a 3 in. round hole in the chassis for the tube socket. The socket consists of a 4 in. piece of Plexiglas with a 2 in. hole cut in it (Fig. 2). Five large tinned forked terminal lugs were purchased from a local automotive store. These could be made to fit the pins of the 3-500Z by springing the part of the lug where the wire normally would be inserted. I bent the forked part at a right angle and bolted to the Plexiglas in position to take the pins of the tube.

The part of the terminal lug taking the tube pins protrudes out and down into the 2 in. hole and air can flow freely around all the pins. Short wide copper straps were run from the forked part of the terminal lugs to the chassis on the three grid pins of the tube when the Plexiglas is mounted under the 3 in. hole in the chassis. This not only effectively grounds the grid pins, but also provides a heatsink for them.

I used an SK-406 chimney, but you could use a chimney from a Coleman double mantle lantern. The lantern chimney sells for under $2, which is quite a savings over the SK-406. However, as the sides of the lantern chimney are straight, they do not deflect the air flow past the plate heat dissipating connector, so the tube should be observed closely that it doesn't overheat. A suggested remedy for this disadvantage of the lantern chimney would be to cement a ring-shaped piece of Plexiglas to one end of the chimney. The diameter would be slightly larger than the diameter of the chimney and the center hole would be 2.5 in.

The HR-6 plate heat dissipating connector must be purchased separately and lists for $2.20, but a supplier that advertises in 73 has them listed in his current catalog for less than a dollar.

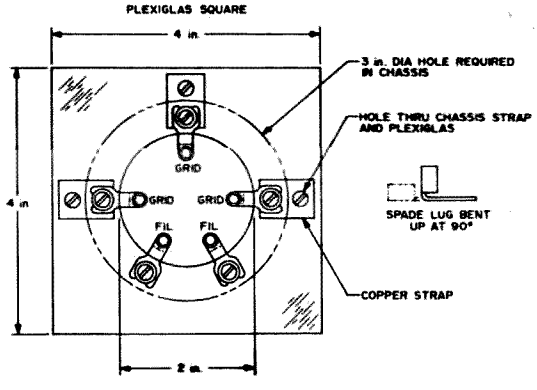

Fig. 2. Layout and plans for the do-it-yourself tube socket.

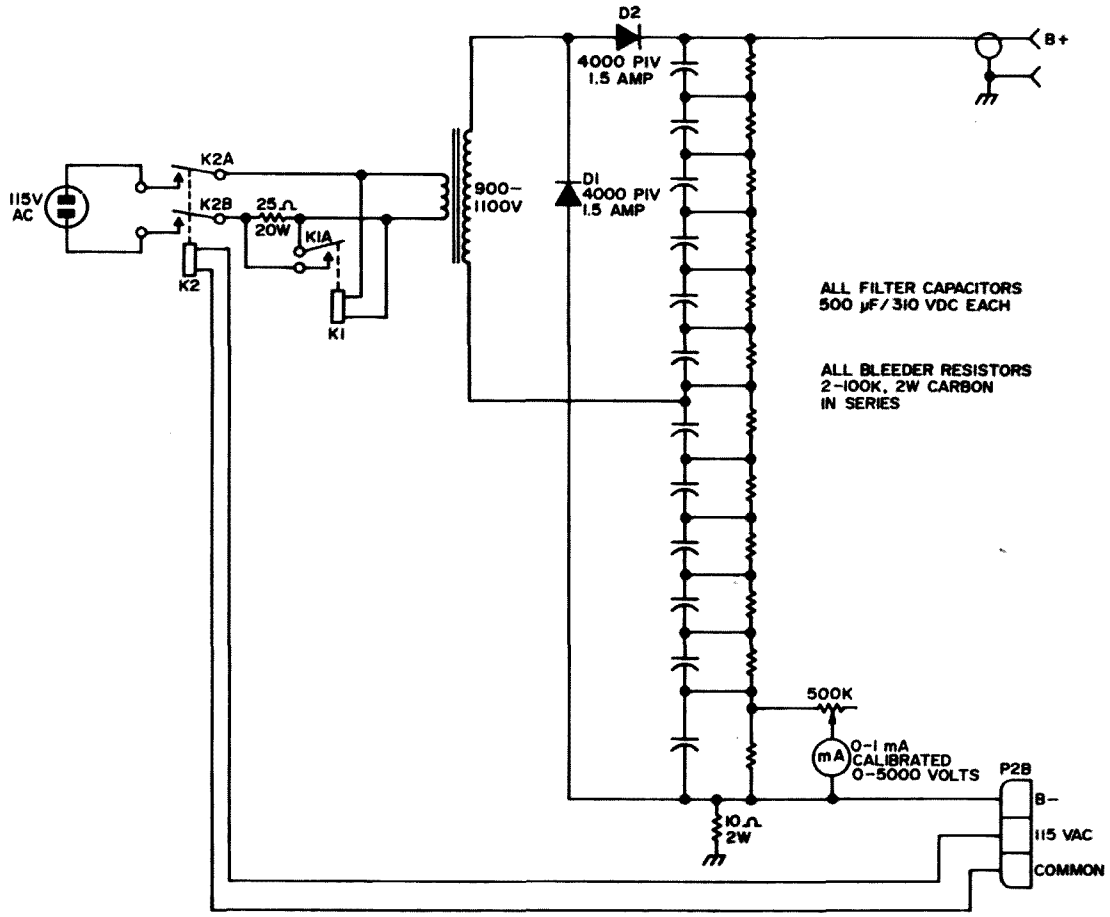

Fig. 3. High voltage power supply.

Power Supply

For the power supply (Fig. 3) I used the filament transformer from an old TV. I removed the shell from the transformer and discovered the filament windings wound on top of the primary with the secondary HV wound on the bottom next to the core. I removed the filament windings, counting the 5V windings, and then wound a new filament winding using the 10-gage wire I used on the filament choke. I taped up the HV secondary leads and they are not being used. The voltage checked out at 5.25V without the tube in the socket and 5V with the tube in the socket and lit. The shell was replaced on the transformer for maximum shielding. In use, the transformer stays cool at all times.

The pi-network is designed around a reactance of 275Ω in the coil, 250Ω in the tuning capacitor, and 30Ω in the loading capacitor. This will give you a Q of 20 if you use a plate voltage of 3 kV. If your plate voltage should only be 2 kV or you should later add a second tube your Q would still be a respectable 10. At 2.5 kV the Q is almost 14. Actual values of L and C are given in the chart on the schematic.

All the metering is done in the negative lead of the cathode circuit. This keeps high voltage off them and allows the grids to be grounded direct. The panel meters are small imported ones that sell for less than $5 each. The voltmeter in the power supply could be mounted in the rf section if desired.

The power supply is of standard design with a full-wave voltage doubler system that gives an approximate no load voltage of 2.8 times the secondary. Voltage regulation will depend on transformer capabilities and house line voltage regulation as well as the output capacitance of the filter. The filter capacitors used here were pur-

chased from an ad in 73 for $1 each and provide over 40 μF of filtering.

A relay and 25Ω 20W resistor was put in the primary circuit of the transformer as shown in the schematic to protect the rectifiers from the high surge of current that occurs when the large filter capacitors are charging. The other relay was installed in the power supply to keep the control wiring to the rf section in a small cable of 20-gage wire.

The power supply is a separate unit. It is in a well ventilated, completely enclosed box that is kept under the operating bench.

Finishing Touches

The rf section is enclosed in a home-made cabinet. I had a local sheet-metal shop cut and bend the aluminum to my specifications. I painted the panel a light gray and the bottom and top cover are painted black. The tube and input circuit are mounted on one side of the cabinet, and the pi-network and filament transformer are in the other half of the cabinet. An access panel was cut in the bottom plate under the chassis and a Roton muffin fan mounted on the cover plate. Rubber feet were mounted on the bottom to let air under the cabinet.

There you have it – a linear that no longer looks like a "Rube Goldberg" special and is pleasing enough to the eye to be placed alongside your exciter. There is, by the way, enough room in the rf section for a second 3-500Z if you have power supply enough to handle it.

SPEC SHEETS – INSTRUCTION BOOKS

While our typesetting and art departments are not exactly undarburdened, they are not all that flat out either. Neither is our printing department, so if you need any spec sheets made up or instruction booklets for your equipment, why not get in touch with us for a quote. We have the technical department to write it, edit it, set it in type, take pictures of the equipment, lay out the booklet or spec sheet, paste it up, and print it. After all, we turn out two rather good sized magazines a month plus a lot of brochures, letters, promotions, and even a fair amount of job work for our locality.

Perhaps you need counter cards, posters, bumper stickers, or almost anything else that is printed or silk-screened?

STUDY GUIDE GENERAL CLASS LICENSE

Part V Something for Nothing

For nearly 50 years, the vacuum tube reigned supreme and virtually unchallenged as *the* amplifier for electronics. From the passing of the spark gap and decoherer in the years following the first world war until the advent of the transistor in 1948, the vacuum tube had no serious competition.

The period of the vacuum tube, not entirely by coincidence, was also the time during which electronic engineering as it now exists made the major part of its growth, and the characteristics of the vacuum tube left their indelible imprint upon the entire field.

And despite the phenomenal growth of semiconductor electronics, some areas yet remain the province of the vacuum tube. UHF amplifiers, cathode-ray tubes such as TV picture tubes, and high-voltage devices are three major regions in which the vacuum tube remains the least expensive device to do the job.

Both because the vacuum tube is still in wide use, and because many other areas of electronics and radio in particular are built upon a foundation derived from vacuum-tube experience, the General class amateur examination contains a number of questions dedicated to determining the applicant's knowledge of vacuum tubes and their operation.

The specific questions in the FCC study list are:

5. Describe the operation and usage of a cathode follower.

8. How is the plate circuit efficiency of a vacuum tube determined?

14. What is meant by the maximum plate dissipation of a vacuum tube?

51. Compare the operating features of the grounded-grid and grounded-cathode amplifiers.

Not one of these four questions makes any sense at all, unless you are already familiar with the principles upon which a vacuum tube operates. Before we can get into the details required for the FCC questions, therefore, we must delve into just how tubes do their job. Then we can examine the various ways they are used and the factors which limit their use, to determine answers to the exam questions.

Our first question, then, will be "How does a vacuum tube work?" When that is out of the way, we can move on to learn "What factors limit a vacuum tube's usefulness?", and finally find out "How are vacuum tubes used?" By the time we get even a brief view of the realms opened up by our final question, we should have adequate knowledge of tubes and their operation to handle any questions such as those on the study list.

With such a broad set of questions, and limited space in which to explore them, we cannot go into excessive detail about any part of vacuum-tube operation. Here, we're only providing enough to satisfy the General class exam questions.

How Does a Vacuum Tube Work?

Before we can determine how a vacuum tube works, we must first determine just what a vacuum tube amounts to. Even though we know that by "vacuum tube" we mean only those gadgets used in radio transmitters and receivers, that still leaves an almost unbelievable amount of territory – diodes, triodes, tetrodes, pentodes,

hexodes, heptodes, multifunction tubes, klystrons, magnetrons. . .The list doesn't go on forever, but it might as well.

All of those special types of tubes share the fact that they consist of electrodes sealed into a tube full of vacuum. Since "vacuum" is defined as the absence of anything else, that's where our phrase about "something from nothing" derives. Unfortunately as we have just illustrated, that's not precise enough to sort out the kind of "vacuum tubes" the exam is concerned with.

Rather than try to define all the differences, let's start with the one common element and see what develops.

We already know that an electrical circuit, to be a circuit, must be complete. That is, it must have both an input and an output. Even the simplest vacuum tube, then, must have at least two different electrodes sealed into its vacuum, one for input and one for output.

The first recorded vacuum tube was just about that simple. It was built by Thomas A. Edison in 1883, and its operation as a vacuum tube was purely accidental. Edison was trying to improve his newly invented incandescent lamp, and one of his experiments was to put a metal plate into the bulb near the filament (Fig. 1). He discovered that when the filament lit, a small electric current flowed between plate and filament. The discovery was duly noted, published, and became known to the world as "the Edison effect." Since it did nothing either way for the operation of the light bulb, Edison apparently ignored it and went on to other inventions – thereby missing the chance to become known as the inventor of electronics atop all his other laurels!

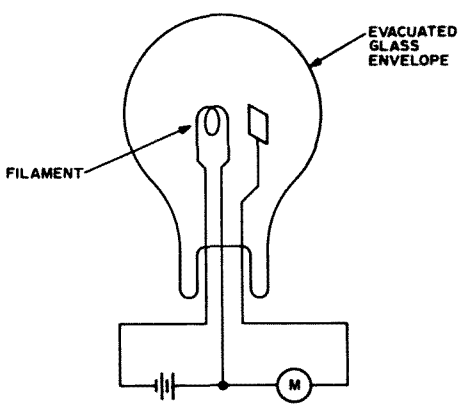

Fig. 1. Vacuum tube owes its existence to Edison effect, discovered by light bulb's inventor. Circuit which revealed Edison effect is shown here. Metal plate was sealed into bulb, near filament but electrically insulated from it. When filament lit, current flowed between plate and filament. More current flowed when plate was connected to positive pole of filament battery, than when connected to negative. Edison didn't know why this happened; others followed it up.

Serious scientists did, however, sit up and take notice of the Edison effect. As a direct result of it, Sir. J. J. Thomson spent several years in study and experiments, and in 1900 or so announced to the world his "electron theory." That's the familiar structure of electrons, protons, and neutrons which we accept now as the "true" picture of the way things are made, and the reasons for electric current.

The electron theory explained the current of the Edison effect as an "evaporation" of electrons from the surface of the filament, caused by the heat energy present in the filament. As these electrons boiled off, some struck the metal plate – and any time we have electrons in motion, we have to have a current. That's the current Edison observed.

Edison also noticed that when he connected the metal plate to the positive side of a battery, the current flow went up, and if the connection was to the negative side, the current went down. This showed that the moving particles had to be negative in polarity, since they were attracted to a positive pole and repelled by a negative one.

A few years later, in 1905, an Englishman named Fleming obtained a patent on a device making use of the Edison effect, which he called a "valve." It was intended to detect radio signals by making use of the one-way property inherent in the current flow from a hot filament to a metal plate (anode). It worked in just the same way as today's diode detector circuits, and it established the vacuum tube as a part of the growing art of radio communications.

Let's look a little more closely at just what goes on in the simple diode, since it was the first vacuum tube to be discovered,

the first to be used, and is still the basis of all conventional vacuum-tube action.

We have, as we have mentioned, two elements inside the vacuum for a diode. One is known as the cathode, and the other is called the anode, or plate.

The cathode is normally heated to a rather warm temperature (between 1000 and 3000°F.) The heating may be done by a separate "heater" which is electrically insulated from the cathode itself, or it may be done by forcing a current through a high-resistance cathode material. Normally, an indirectly heated cathode makes use of a "heater," and the word "filament" is reserved to mean a combination heater and cathode. So far as the basic principle of operation is concerned it doesn't make much difference where the heat comes from so long as it's present, but in practice if ac is used to provide heating power it's better to keep the ac out of the signal circuits, and so the heater–cathode combination is most frequently encountered in ordinary tubes.

At the cathode temperature, some of the electrons of the cathode material literally boil off into the empty space surrounding the cathode. This forms a cloud of electrons known as the "space charge" around the cathode itself.

The plate or anode is separated from the cathode by distance, and it's far enough away that the space charge never quite reaches it.

Under these conditions, with no voltage applied between plate and cathode, the space charge is self-limiting. It always contains all the electrons emitted (boiled off) from the cathode, and so always has a negative charge which just balances the positive charge produced on the cathode by loss of the electrons.

If the temperature of the cathode is raised so that more electrons are emitted, the space charge will increase, but the current flow to the plate will remain essentially zero. Similarly, if the cathode temperature is lowered, the plate current will remain unchanged at zero.

If we return the cathode to "normal" temperature and put a small positive voltage on the plate, the picture changes. The positive voltage on the plate attracts some of the electrons from the space charge, and a current flows between plate and cathode.

Not all the emitted electrons reach the plate, though. When we put voltage on the plate, this created a "voltage gradient" from cathode to plate something like a hill in the path of the emitted electrons (Fig. 2), and only those electrons which left the

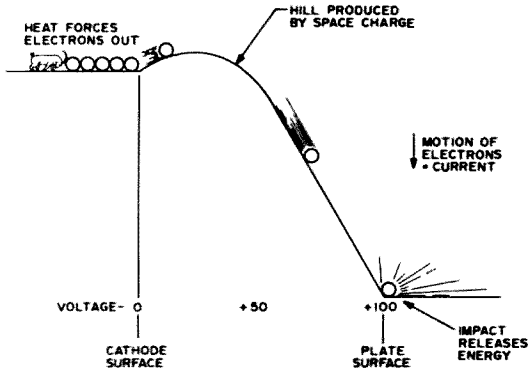

Fig. 2. Action of electrons inside simple diode tube is shown here. Difference in voltage between cathode and plate surfaces forms a "voltage gradient" shown here as a downhill slope. Space charge puts a hump in this hill, near the cathode. Angry ram represents action of heat, boiling electrons off the cathode surface. Those electrons with enough energy to make it over the hump fall down the hill, and hit the plate with a crash, releasing more heat.

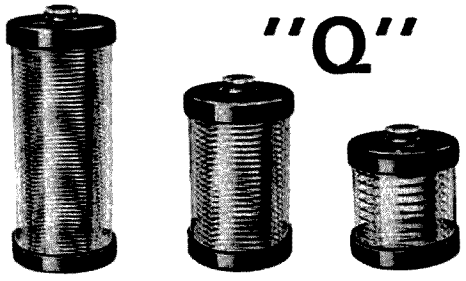
cathode with enough energy to "make it up the hill" go to the plate. Some are repelled by others in the space charge, and a few even return to the cathode as a result.



Making the cathode hotter doesn't change things much – but if we cool it down somewhat, the number of electrons in the space charge is reduced and we find that the "hill" is not so steep. As the temperature cools, we find one point at which all the emitted electrons go over to the plate.

We can achieve the same effect without changing cathode temperature if we simply increase plate voltage. When plate voltage is high enough, it will pull all the electrons over the hill.

In a diode, we have only these two factors available with which to vary the

plate current. If either stays constant, the other exercises control (so far as it is able). With constant plate voltage, cathode temperature will determine the current up until the increased space charge with increased temperature makes the hill "too high" for the plate voltage to pull electrons over. With constant cathode temperature, plate voltage will be the ruling factor until it is great enough to pull all the electrons over the hill, at which time temperature again takes over.

This "hill" effect determines the maximum power dissipation rating for the tube, in a slightly indirect manner. The "hill" is *between* cathode and plate, so that electrons leaving the cathode must "climb up" the hill to get past it, and those which reach the plate are "falling down" the other side. (The analogy to a hill is not quite real, but if the voltages are plotted on a graph as in Fig. 2 it's close enough for all practical purposes.)

The more electrons that hit the plate, or the harder they fall, the more shaken will be the molecules of the plate material. This shaking up of molecules is what we generally call heat, and a large amount of it goes on in a typical vacuum tube. Plates often run at a dull red glow, and some tubes are designed to operate with their plates white hot – with the heat *all* coming from the impact of the electrons falling down the "voltage hill" between cathode and plate.

Any material eventually gets hot enough to melt, and the plates of vacuum tubes are no exceptions to this rule. For this reason, any tube is rated for a "maximum plate dissipation" which is the power in watts the plate can safely convert into heat. Power is the rating factor because it includes current (the number of electrons hitting the plate) – and voltage (the hardness with which they fall). It's also easy to calculate and to measure, in operation.

While we've explained "power dissipation" ratings in terms of the simple diode, it's the same situation for any kind of tube. Not only the plate is involved, either. Any electrode which is more positive than the cathode (on the "downhill" side of the voltage hump) must dissipate the impact energy of the electrons that get to it, and

such electrodes are individually rated for maximum power dissipation.

The diode's main usefulness in radio today is as a polarity-sensitive switch (Fig. 3). If the plate is positive to the cathode, it conducts a current, while if the plate is negative, the electrons are repelled and

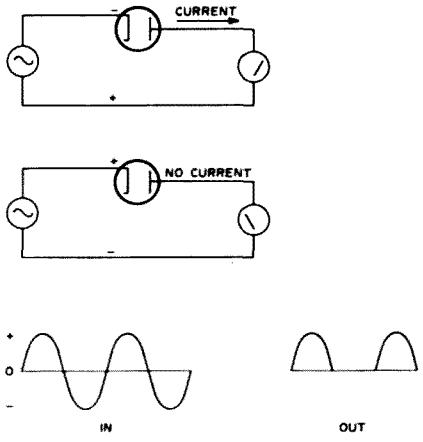

Fig. 3. Primary use of diode in electronics today is as a switch. When plate is positive (top) current can flow. When plate is negative (center) no current flows. This action can be used to change ac input into pulsating dc output (bottom), or to detect the envelope of an amplitude-modulated radio signal, as well as for many more exotic uses not strictly a part of radio.

current flow stops. This makes it useful as a power rectifier to change ac to pulsating dc, and also as a nonlinear device for modulation, mixing, and detection of signals (which we'll explore later).

The first great advance over the diode came about when Lee DeForest surrounded the cathode with a coil of wire which he called the "grid" (Fig. 4). By applying a negative voltage between the grid and the cathode, it became possible to add a new dimension of control.

For proper operation of a triode, as the three-element tube is known, cathode temperature and plate voltage are kept in the range where plate voltage controls cathode current. The plate is kept positive to permit large currents, but the grid is kept negative so that it repels electrons from its neighborhood and so holds down the plate current.

The effective "size" of the grid, as it shows up in its interference with plate

current, depends upon the voltage applied to it. The more negative the voltage, the more effectively the grid blocks current flow. It's possible with most tubes to bring plate current down to zero by putting an extremely negative voltage (known as "cutoff voltage") on the grid. If, on the other hand, the grid is allowed to reach a positive voltage, it acts just like another plate, and loses its control of current flow.

For normal amplifier operation, the "bias" voltage applied to the grid is somewhere between the limits of cutoff and positive voltage, and is chosen so that the variation in plate current which results when small changes occur in the grid voltage is a reasonably true replica of the variations in the grid voltage. Picking the right combination of plate voltage, plate current, and grid bias to achieve this happy effect is one of the fine points of engineering design work which we won't go into deeply right here.

For our purposes, we can think of the tube as something a little different. As we mentioned in our previous installment, either a tube or a transistor can be considered to be just a resistor in the circuit from cathode to plate, with the value of the resistor being controlled by the grid voltage.

This is a somewhat unconventional approach to the matter – and one you won't find in any engineering testbooks – but it works. Keep in mind that the more

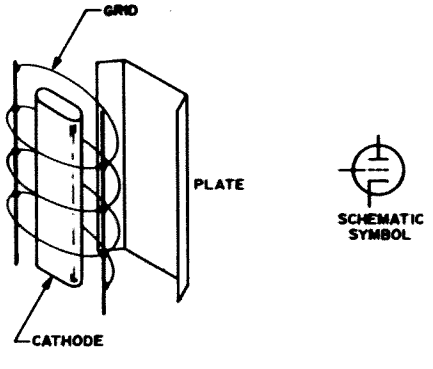

Fig. 4. Introduction of grid between cathode and plate made it possible to control cathode current by means of a separate isolated electrode, and gave birth to electronic amplification as we know it today. Appearance of simple triode is shown at left; schematic symbol is at right.

negative the grid-to-cathode voltage, the more ohms in the "resistor" presented between plate and cathode connections, and the less negative the grid, the fewer ohms in the "resistor." As grid voltage goes positive, then, the resistance value goes down and more current flows. If the tube is in series with a fixed resistor, this will reduce the voltage at the plate, and we have a change in plate voltage which is brought about by the change in grid voltage which is 180 degrees out of phase.

When used in this manner as an amplifier, the triode vacuum tube operates almost exactly like the transistor except that its resistance is controlled by the *voltage* on its grid rather than by the *current* injected into the base, and it uses somewhat higher voltages than do most transistors.

However, both the triode and the transistor share a common problem. The grid and the plate are both conductors, and they are separated by an insulating medium. This makes them form a capacitor – which permits some of the plate voltage to feed back to the grid. This plate-to-grid capacitance makes the triode tricky to handle as a radio-frequency amplifier (and the transistor too, for that matter, but we're talking about tubes at the moment).

To solve the problem, another grid structure was introduced between the original grid (now called the "control" grid) and the plate. The new grid, being added to screen the control grid from the plate, was called the "screen" grid. It was, like the plate, connected to a positive voltage so that it had little or no effect upon the electron stream passing through, but was bypassed through a capacitor to ground to prevent any signal from coupling back through grid–plate capacitance.

The screen grid worked nicely, and the resulting structure is known as a "tetrode" because it has four elements. However, it introduced a new problem. Sometimes the plate voltage is driven to a value *lower* than the screen voltage. Electrons still hit the plate hard – hard enough to knock a few "secondary" electrons free. These secondary electrons then went to the screen

rather than returning to the plate. The result was an effective "negative resistance" between plate and screen under certain conditions, which could cause oscillation.

The direct cause of this effect was the fact that the screen was the most positive thing around when secondary electrons were released. A direct cure was installation of still another grid, the third, between screen and plate. This "suppressor" grid is connected to the cathode, so that it will be more negative than either screen or plate. When secondary electrons leave the plate now, the negative charge on the suppressor grid drives them right back where they came from.

With five elements – a cathode, three grids, and a plate – the resulting tube is known as a pentode. Most present-day rf amplifier tubes are pentodes. Some power tubes are "beam power" tubes; they make use of special beam-forming plates attached to the cathode, which focus the electron beam in such a way as to create a "virtual suppressor" by space-charge effect between screen and plate.

Each of the additional electrodes introduces a small amount of noise into the signal. Normally this is of no consequence, but in critical applications such as the first stage of a VHF receiver, triodes are still preferred despite their problems simply because of their low noise.

The many other kinds of tubes you may meet are, for the most part, combinations of the kinds we've examined here. They all start out with the elements of a diode, and all conventional tubes then add grids as necessary to do their job. Often two or more separate tubes are combined in the same envelope for convenience (the 6U8A (Fig. 5) is an example of a triode and a pentode sharing the same chunk of glass), but the essential structure remains unchanged.

What Factors Limit a Vacuum Tube's Usefulness?

The vacuum tube is a most useful gadget, but each individual one is limited in its use by a number of factors. One of these, power dissipation, we've already met. Some of the others include such things as the circuit efficiency, operating frequency limits, and power requirements.

The major limits on any specific tube are those set by its power requirements, power dissipation, and operating frequency limits. The power requirements include both the power necessary to heat the cathode and that required to operate the tube's plate circuit (and screen, if any). Power dissipation involves not only the ratings, but the method by which the tube is cooled. Frequency limits are usually one-sided. Almost all tubes will operate at frequencies down to and including zero (or dc), but every tube has an upper frequency limit beyond which it will no longer act as a tube should. Let's examine these in reverse order, looking at the frequency limits first.

The absolute frequency limit in any tube is set by the physical distance between its electrodes. The electrons in the tube do *not* travel at the speed of light; they take a definite amount of time to make the trip from cathode to plate. If the signal frequency is so high that the distance from cathode to plate is an appreciable part of a wavelength, then everything goes sour. For instance, a positive-going signal at the grid should increase plate current – but if it's a half-wave from grid to plate, the plate current will be decreasing at that instant rather than increasing, and cannot increase until a half-cycle later when the grid signal is going negative.

Almost no tubes actually make it up to this limit, though. Other factors impose even lower frequency limits on them. One is the combined effect of the cathode

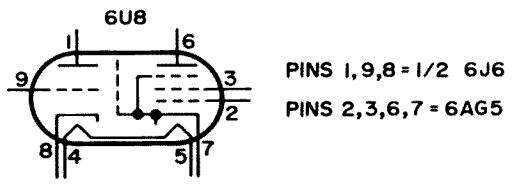

Fig. 5. Combination tube such as type 6U8 is actually two different tubes enclosed in same glass envelope and sharing same heater for convenience. Triode half of 6U8 is same as half a 6J6, while pentode portion is same as a 6AG5. Portions can be used independently.

WHEN IT COMES TO ANTENNA SYSTEMS... IS YOORS
a space problem? a budget problem? an applications problem? an installation problem? or simply a problem of where to buy?

Your one-stop solution is ANTENNAS, INC.
Exclusively specialists in radiating systems, complete systems or any component part.
Arrays—complete or in kit form, quads, yagis, dipole assemblies, verticals—fixed or mobile, towers, masts, rotors, guy and control cable, transmission line, coax relays and switches, connectors and adaptors, test gear, technical publications, corrosion resistant hardware, corrosion proofing chemicals, insulators, installation and wiring hardware, aluminum tubing and plate, wire, and much, much more.
If your requirements are for a complete system, major components, or the smallest yet important piece of hardware—

Our prices and deliveries are hard to beat . . . anywhere.

structure's own inductance and the capacitance from cathode to each other element in the tube. Taken all together, these effects add up to a low-pass filter circuit which prevents any signals above the filter's cutoff frequency from flowing through the cathode – and so makes the tube unusable at these higher frequencies.

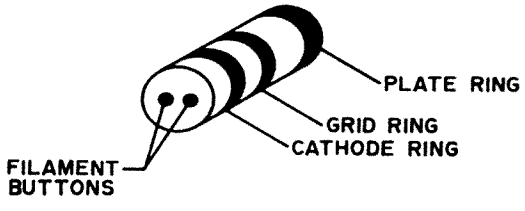

Fig. 6. In quest for UHF operation, tube designers have come up with strange designs. One is this "planar" triode which is made of ceramic, with electrode connections coming out as rings around tube body to eliminate lead inductance as much as possible. Tube operates well into UHF region, but still has an upper frequency limit.

Tube designers combat these limits by making tubes intended for VHF operation physically small, and providing multiple connections for all elements. An extreme example is the family of tiny "planar" triode tubes made for space use, which have no connector pins as such. Instead, each element is brought through the envelope as a ring (Fig. 6). Distance between elements is reduced to thousandths of an inch. The tubes operate far into the UHF region – but they still do have frequency limitations.

Power dissipation comes about because the electrons which compose the cathode current have energy, and release it in the form of heat when they get where they're going, as we already saw. The limiting factor here is almost always purely physical; when things get just so hot, they melt. It's not uncommon to see overloaded power tubes with large dents in their glass envelopes, where heat has softened the glass to such an extent that anything can change its shape!

The type of cooling provided has a lot to do with the limiting effects of power dissipation. If a stream of cool air blows past a tube, it can handle much more heat than if it is sealed into an airtight box of polished aluminum. Very-high-power tubes are often liquid cooled, with water actually flowing through the interior of the plate structure just like an automobile engine's cooling jacket. Published ratings usually assume good ventilation is provided.

Power requirements limit the usefulness of tubes in a number of ways, most of them indirect. In comparison with a transistor, for instance, a tube requires much more power – so much so that the vacuum-tube portable radio is almost extinct now. More power is necessary for heating the filament of just one radio tube than is used by all the transistors of an average pocket receiver.

Similarly, in the case of mobile radio equipment, those tubes which require extremely high plate voltage supplies, or high current, are usually ruled out because operating power is limited.

In some instances, even when high voltage and high current are available, the comparative danger of high-voltage oper-

ation as compared with low-voltage circuits (transistors, etc.) tends to swing the choice away from the tube.

Circuit efficiency also limits the usefulness of any circuit, not just those using tubes. In general, the efficiency of any circuit is the ratio between power put *into* the circuit and power taken *out*. For vacuum-tube amplifiers, it's sliced a little thinner in the standard definition of plate circuit efficiency.

Plate circuit efficiency, according to this definition, is the ratio of *signal* power output to *supply* power input (Fig. 7). It

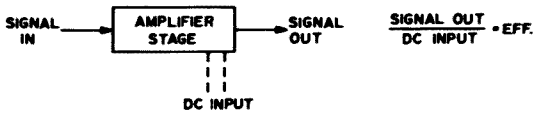

Fig. 7. Efficiency of an amplifier or a circuit is figured as shown here, by dividing signal output power by dc power put into the stage. Input signal power is ignored in the calculation.

has nothing to do with signal power input. Thus, an rf amplifier which operated on 1 kV plate supply and drew 500 mA current would take 500W from the supply. If it delivers 300W of rf output, its plate circuit efficiency is 60%.

While circuit efficiency up to 95% or better is possible on paper, almost no working circuit has ever been built which gets better than 75 to 80% efficiency. The trouble with the higher efficiencies is that they measure all rf power output, not just that at the signal frequency. In order to get figures above 75%, it's necessary to choose operating conditions which greatly increase the percentage of harmonics in the output – and all the "extra" output power consists of just those harmonics!

Most audio power amplifiers are far less efficient than this. Typical figures are around 20 to 25% for "moderate" distortion. We'll get into this a bit more a little later when we look at some of the ways in which tubes are used.

The definition of plate circuit efficiency contains a built-in loophole, and in the early days of SSB operation many operators took advantage of the same loophole (which was also in the FCC rules at that time). The loophole is this: signal power input is not taken into account.

Some types of amplifier circuits use only a small fraction of the input signal as input, and feed the rest right on through into the output circuit. Such an amplifier can, for instance, accept 100W of signal input power, amplify 10W of it by a factor of 30 to get 300W, and feed through the remaining 90W of input to the output. The output power will be 390W, yet the amplifier produced only 300 of them. If input power were to be reduced to 10W, output would drop only to 300. And in either case the dc supply power taken by the circuit would be the same. This means that the same circuit might produce 300W at an efficiency of 60%, or 390W at an efficiency of 78%, with no change in the circuit or its adjustments!

For the definition of efficiency, this loophole is closed by requiring that only the power output *produced by that circuit* be used in calculating efficiency.

The loophole in the rules had to do with the maximum power limit. It was originally stated as "1 kW to the transmitter stage which delivers power to the antenna," and the fellows who found the loophole went through it by using a 1 kW final of a type which could feed through almost unlimited power, and driving it with a 10 kW "driver." Most of the 10 kW, of course, would go right on up to the antenna, with apparent efficiency in the final of several *hundreds* of percent.

The loophole no longer exists. Part 97.67 of the current edition of the Rules and Regulations states that power input shall now be measured to "the tube or tubes" delivering power to the antenna, and the Commission has served notice that in the case of feedthrough amplifiers, this is interpreted to include all driver stages as well.

How Are Vacuum Tubes Used?

While at first glance it would appear that vacuum tubes are used for many purposes, we can compress all the uses for the ordinary garden variety of tube (that is,

all except such special-purpose items as TV picture tubes, oscilloscope CRTs, tuning indicators, and the like) into one, with our "voltage-variable resistance" concept introduced in the previous section.

The diode, for instance, when it is being used as a rectifier, changes from being a very high resistance (when cut off) to a relatively low resistance (when turned on). The amplifier simply controls the flow of current between two terminals in response to the voltage between one of the two and a third. The oscillator is simply an amplifier connected in a special circuit. Even the digital logic circuits used in early electronic computers for timing and storage can be viewed as resistances controlled by voltages.

The exact characteristics of any individual type of tube such as, for instance, the 6C4 triode, depend upon the materials from which it is made, and primarily upon the shape and spacing of its electrodes.

These shape and space factors are generally called the "internal geometry" of the tube type, and they fix the amount of effect the grid voltage will have upon plate current, the maximum plate dissipation, the maximum cathode current, etc.

If you know the geometry of the tube – or what amounts to the same thing, know what its effects are – you can apply the tube in almost any way you like. To make life easier for equipment designers, the people who design and build tubes run measurements upon their products and publish "characteristic curves" which describe the key factors.

A typical characteristic curve for a triode (Fig. 8) graphs plate current against plate voltage for various values of grid voltage. A not-so-typical curve might graph plate current against grid voltage, for various plate-voltage values. For most designers' purposes, though, the plate-current/plate-voltage curve is best, so it's the one most often supplied.

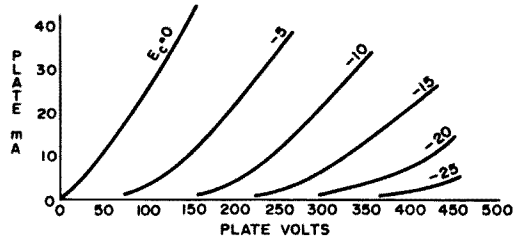

Fig. 8. Typical set of plate-voltage/plate-current curves for a triode tube shows relation of plate milliamperes to plate volts for six selected values of grid voltage. Relationships for other grid voltages must be interpolated between these, if they are needed.

However, if we know plate current and plate voltage at any instant, then by Ohm's Law we can determine the effective plate-to-cathode resistance represented by the tube.

If the tube's plate is working into a reactance rather than a resistance, as for instance the primary of a transformer, or a choke-coupled output circuit, the plate voltage averages out to be constant and the manufacturer's curves can be used as they are. Changes of grid voltage then change only plate current.

If the plate works into a resistor, as in a resistance-coupled amplifier, it's a bit different and the picture gets messier. A "load line" must be drawn on the curve to determine the dc plate voltage present at any instant.

By using the curves, together with his accumulated training and experience, the equipment designer picks an "operating point" for the tube by proper choice of the plate and grid voltages, so that the change in grid voltage will cause a corresponding change in resistance between plate and cathode. That is, if a 0.5V increase in grid voltage causes a 10% drop in resistance, a 1V increase of grid voltage should cause a 20% resistance drop and a 1V decrease at the grid should result in a 20% increase of resistance. These figures are, of course, merely examples and do not correspond to any actual circuit.

When this had been done, the result is a circuit which produces for its output an "amplified" or stronger version of the input signal. The "linearity" of amplification is a measure of how accurately the output follows the input; another phrase used for the same effect is "distortion."

Notice particularly that this same process occurs in any kind of amplifier based on tubes or transistors, no matter what the circuit's name may be. Class A, B, or C amplifiers, as well as grounded-grid,

grounded-cathode, and cathode-follower circuits, all act on this same basic process.

The terms "class A," "class B," and "class C" describe the operating point of the circuit. A "class A" circuit is intended to produce low distortion, and to give an output which is a faithful replica of the input. A class B circuit's operating point is much closer to the cutoff point (a true class B circuit operates exactly *at* cutoff); output is distorted but efficiency is higher. A class C circuit remains cut off most of the time and passes current only during the peaks of the input signal. Output is distorted beyond recognition but efficiency is highest under these conditions. Since the distortion can be removed from a continuous (unmodulated) rf signal by a resonant circuit, class C amplifiers are used for rf.

As we have already learned, any circuit requires two conductors to complete it; we can think of one as the "hot" lead and the other as a "return" path for the current. The usual "return" past in most radio equipment is the chassis, which we refer to as "ground" or "common" since it is often connected to ground, and provides a common return for all signal paths.

Our vacuum tubes, with their associated components, convert an input signal into an output signal. This means that four conductors are involved, two for each signal. The return for each signal, however, is almost invariably grounded, which reduces the number of conductors to three – an input "hot" lead, an output "hot" lead, and ground. This is fortunate, since a triode tube has only three elements; we have exactly enough conductors to assign one conductor to each element; with neither elements nor conductors left over.

Because of the physical means by which the tube does its job, the input *signal* must be applied between grid and cathode, and the output signal must be taken from plate and cathode. However, this does not necessarily mean that the cathode must be connected to ground, input to grid, and output to plate.

While it's true that the most conventional use of tubes follows just that assignment (called grounded-cathode operation), we can connect our common ground to any one of the three elements (Fig. 9). If, for instance, we ground the grid, then we must apply the input between cathode and ground. In order to take output with only one wire at the plate, we must pass all the output current through the input circuit. That is, since the input is connected to the cathode, the output signal's path must go through the input to get to the cathode in order to reach the plate.

Similarly, we could ground the plate. The input signal is now applied between grid and plate, while the output signal is taken from cathode and plate. For the input to get to the cathode, it must travel through the output circuit.

This means that in both the grounded-grid and the grounded-plate (usually called cathode-follower) circuits, the input and output circuits are directly connected. In the grounded-grid circuit, they are in series, so that all the current of one must pass through the other, while in the cathode follower, they are in parallel, so that the voltage of one becomes the voltage of the other.

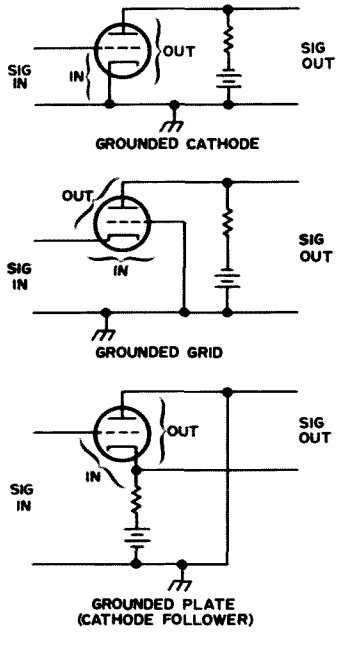

Fig. 9. Differences between the three ways of connecting tubes in amplifier circuits are shown here. These are simplified schematics and leave out all the necessities such as grid bias, coupling capacitors, etc., to emphasize the similarities and differences of the three different circuit types.

Our 25th Year.
1946 to 1971

In the conventional grounded-cathode circuit, the input and output circuits are isolated and do not interact so directly.

The apparent differences between these three different circuits are due primarily to this difference in relationships of input and output signals. In the grounded-grid circuit, a small input voltage causes a large change in plate current – which forces a large change in input current because of the series connection. This makes the circuit look like a low impedance to its input, and a very high impedance to the output. It also permits feedthrough of power from input to output.

Since it's voltage rather than current which interacts in the cathode follower, the effects are reversed. Input impedance is very high, and output impedance is very low. Coupling of signal from input to output is small; voltage gain is always less than 1, which means that a cathode follower actually introduces a voltage loss.

The gain of any individual tube is determined by the internal geometry of the tube, together with the applied voltages and currents. If voltages and currents are the same, the tube must provide the same gain in any of these three circuits. The stage, however, need not deliver the same gain.

For instance, a conventional grounded-cathode amplifier has its input and output circuits separated and minimizes interaction between them. In such a circuit, the stage gain can approach the maximum of which the tube is capable. Both the current and voltage of the input signal can be made larger in the output.

A grounded-grid stage, however, has its input and output circuits in series, so that the output current and input current must always be the same. Its gain can affect only the signal voltage. Thus the current gain of the grounded-grid amplifier cannot exceed 1, but high voltage gain is possible. While the gain of the tube itself remains high, the interaction between input and output signals outside the tube reduces stage gain.

The cathode follower has its input and output circuits effectively in parallel, so that the voltage in an;out must be approximately the same. Its gain can affect only current. Voltage gain cannot be greater than' 1, but high current gain is possible. Again, the tube gain is unchanged, but the input/output interaction outside the tube provides the restricting factor.

Since both the grounded-grid and the cathode-follower circuits produce less gain than does the grounded-cathode arrangement, and since amplifiers are usually intended to produce gain, this gives rise to the question "Why use these inefficient circuits?"

Each of them has its own unique properties, which provide certain advantages in special situations. When the properties are not needed, the special circuits aren't used.

The grounded-grid amplifier reduces the stray coupling between input and output circuits inside the tube, because the grid acts as a shield between cathode and plate. This makes it possible to avoid having to "neutralize" a high-frequency amplifier, and in some cases makes it possible to operate a given tube at a higher frequency than would otherwise be possible (by modifying the effect of the built-in "low-pass filter" we examined earlier).

In addition, the low input impedance of the grounded-grid circuit is often convenient for a high-power rf amplifier, and the capability of feeding through power from input to output is also nice (although no longer offering a loophole in the FCC regulations).

Contrary to popular opinion, there is no appreciable difference in amplification quality between a grounded-grid amplifier and one using the conventional grounded-cathode circuit. Quality in each case depends upon proper adjustment of operating point and input signal level, not upon the choice of the common electrode.

The cathode follower's special properties depend upon its high input impedance and low output impedance. This makes it ideal for use in transforming impedances from high to low levels. The input capacitance is reduced by the same factor that input resistance is increased, making the cathode follower an excellent device for coupling energy out of critical circuits such as rf oscillators. The low output impedance makes it capable of driving a feedline without any intervening transformer, although other factors make this idea less attractive than it may sound at first.

The cathode follower offers an ideal example of "feedback" in action; this is an important idea in all electronics, and seldom appears so clearly illustrated as in the cathode follower. Let's take a conventional grounded-cathode circuit and change it, step by step, into a cathode follower to see how feedback provides all the special characteristics of the cathode follower while the tube itself continues to operate just as it did before.

We'll start with an imaginary triode which operates normally with a plate-to-cathode potential of 100V, a cathode-to-grid potential of 5V, and a plate current of 10 mA. Under these conditions, with a 10 kΩ resistor as its load, the tube provides a voltage gain of 21 times (Fig. 10). That is, a 0.1V change in grid voltage will change the plate current by 210 μA, causing the plate voltage to change by 2.1V. A 1V change in grid voltage will change plate current by 2.1 mA, causing a plate voltage change of 21V.

Now let's move 1 kΩ of the plate load resistor around to the cathode circuit, leaving 9 kΩ in the plate lead (Fig. 11). This 1 kΩ in the cathode circuit is in both the cathode–grid circuit and in the plate–cathode circuit, so that the plate path still sees 10 kΩ.

If we change the grid voltage by 1V, the plate current will change by 2.1 mA. This will increase the cathode voltage by 2.1V (if the grid is going positive so that the current increases) and decrease the plate voltage by 18.9V. The plate–cathode voltage change is still 21V. The output voltage change would be less than that, however.

Unfortunately, the 2.1V change in cathode voltage is of such a polarity as to *reduce* the effect of the 1V input signal; were the entire 2.1V increase to occur, it would completely cancel the input signal

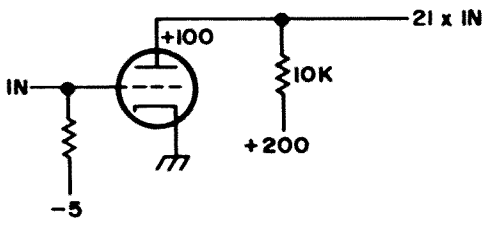

FIG. 10

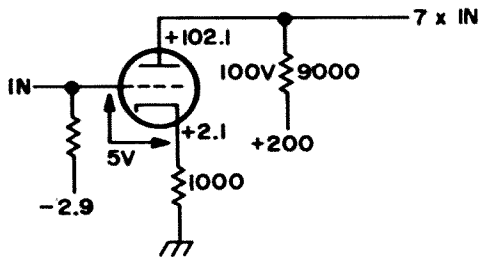

FIG. 11

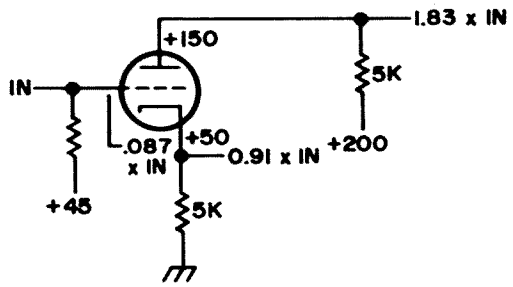

FIG. 12

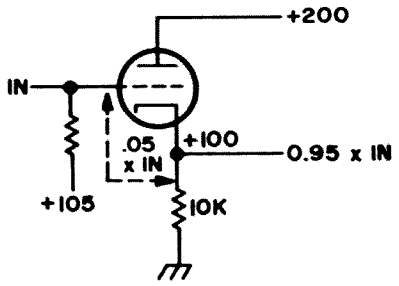

FIG. 13

Figs. 10–13. These four schematics illustrate how feedback introduced by resistance in cathode circuit reduces stage gain although tube itself continues to operate unchanged. Voltage applied to grid maintains grid-to-cathode voltage at 5; as cathode voltage changes, grid voltage is changed to always be 5V less.

which produced it. This, of course, cannot happen. What does happen is this:

The *effective* input signal is the one between grid and cathode, while the actual input signal is between grid and ground. When the grid voltage goes up 1V, it cannot do so instantly but must increase a few millivolts at a time. As it does so, the cathode voltage comes right along behind to buck it – and at some point they meet and level off so that 1V applied between grid and ground produces a grid-to-cathode voltage just right to permit the cathode-to-ground voltage at that instant.

In our example, this will happen when the grid–cathode voltage is a little higher than 0.322V. The cathode current increase caused by this voltage is a little more than 0.67 mA, and the rise in cathode voltage is about 0.676V. The two voltages add up to 0.998 – which would have been 1.0 except that we rounded off our figures.

The "feedback" voltage appearing across the cathode resistor, then, reduced the effective input voltage to a smaller value. This in turn reduces the output signal voltage, since there is less input signal available to the grid. Stage gain is reduced – but the tube itself is still providing a 21-time voltage gain.

Input resistance of the stage increases, because resistance is defined as voltage divided by current (Ohm's Law). Only the effective input voltage sees the original stage input resistance, but the entire input signal is affected. This means that the original input resistance must be multiplied by the same value that the voltage is divided by in order to keep current constant. In our example, the effective voltage is about a third of the actual voltage, so the effective input resistance is three times that of the original circuit.

Now let's move some more of the resistance from the plate circuit to the cathode (Fig. 12). This time, let's make it 50/50, with 5 kΩ in each.

The feedback causes the effective signal input voltage to be smaller than the actual input, just as before, only more so. Where in our first example the cathode voltage rose 2.1 for every volt increase in grid–

ELECTRA CORPORATION • CUMBERLAND, IND. 46229

cathode voltage, it will now rise 10.5 because of the greater resistance.

Effective stage gain under these conditions is reduced from 21 times to about 1.83 times. That is, a 1V input signal from grid to ground will produce an apparent 1.83V change in plate voltage – which means a 183 μA change in plate current.

This means that the increased cathode resistance caused the leveling-off to occur with an effective input voltage of only about 0.087V. The remaining 0.913V of the input signal was bucked out by cathode voltage.

Input resistance, similarly, is much greater now.

If we move all 10 kΩ over to the cathode circuit (Fig. 13), we find that effective stage gain is down to 21/22. That is, a 1V input signal will cause a 0.954V change in cathode voltage. The effective input between grid and cathode, then, is only about 0.05V. The tube is still producing its 21-time gain, because 0.05 times 21 is 1.05 (actually the input is a little less than 0.05, providing 0.95V out). Input resistance is now 21 times larger than originally.

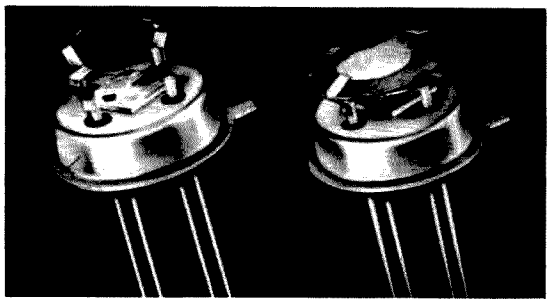
The cathode follower circuit we have just developed can accept much larger input signals than could the grounded-cathode circuit with which we began. For instance, we had a 5V bias on the grid at the beginning, which meant that any input signal more positive than 5V would carry the grid positive (a condition to be avoided in most cases). With the approximate 20-time division of actual input voltage produced by the cathode follower's feedback, a 5V input signal is effectively reduced to 0.25V, and even a 20V input signal is effectively cut back to 1V from grid to cathode.

Where originally we ran out of the operating range with a 5V signal, we can now go up to a 100V signal without exceeding the same operating limits.

This is not the only advantage produced by controlled feedback. The changes in input and output impedance are also due to feedback's modification of effective voltage and current levels. Not so obvious is the fact that any distortion introduced by the tube is reduced, because it is *not* a part of the original input signal.

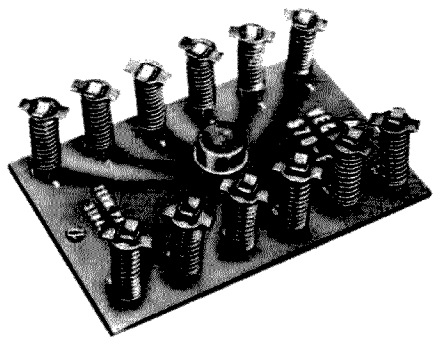
The grounded-grid amplifier's characteristics of low input impedance and high output impedance are also the result of feedback; in the grounded-grid circuit, it is current that feeds back rather than voltage, and this reverses the effect upon impedances.

Feedback also makes oscillation possible, if the feedback voltage boosts the input signal rather than bucking it. We'll go into all this in another chapter, however, when we examine practical amplifiers and transmitter circuits.



A Place to Start

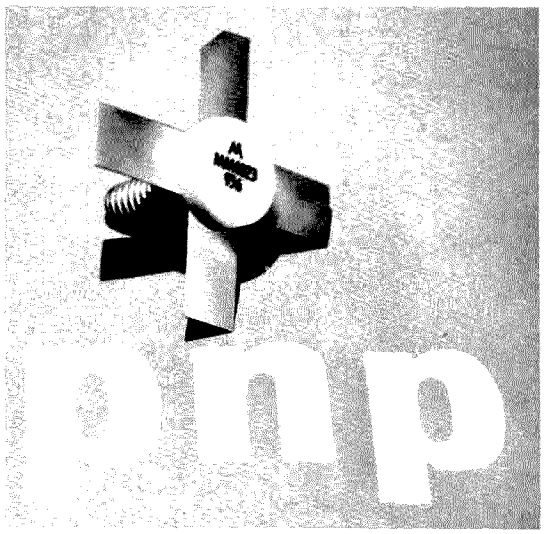
By this time, we've fairly well covered the basic components and ideas upon which electronics and radio theory are built. With our foundation established, we're ready to begin putting things together into operating circuits. One thing which any circuit must have is a source of power, so the power supply is a good place to begin our study of practical circuit theory. . . . Staff ■



NEW PRODUCTS

Crystal-Controlled Microcircuit

A crystal-controlled microcircuit oscillator (Model MCO-F), which uses thin-film capacitors and resistors on a single substrate, is totally contained within a 4-lead TO-5 Koldweld package. The new unit is designed for application as the local oscillator or second mixer in dual-conversion receivers. It is especially suited for use in advanced paging and personal portable receivers where rugged environmental conditions may be encountered. *TRW Electronics, 1100 Glendon Ave., Los Angeles CA 90024.*



IC Breadboard Socket

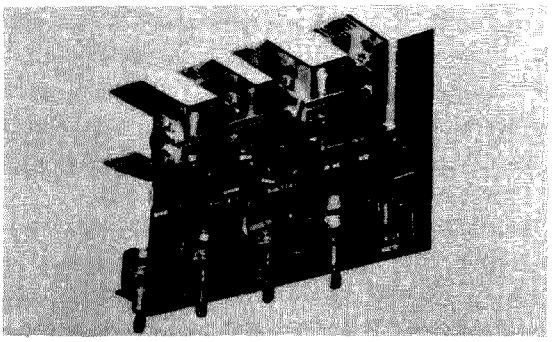
A new device is now available for breadboarding with 12-lead, round TO-5 integrated circuits. The device consists of an epoxy glass wafer, 2-3/8 x 1-5/8 in., on which is mounted a 12-pin socket, the tabs of which have been soldered to two adjacent rows of reliable solderless terminals.

The device should speed IC breadboarding because as many as four solderless connections can be quickly made to any terminal pin with ordinary hook-up wire. If discrete components are required, they may also be easily connected. *Vector Electronic Co., 12460 Gladstone Ave., Sylmar CA 91342.*

Power Transistor Line Expanded

Four new transistors have been added to the industry's only line of silicon PNP rf power devices. The transistors, types MM4020 thru MM4023, bring to nine the number of devices in Motorola's PNP rf power family and increase the variety of output powers available to the designer. These now range from 0.5W to 40W @ 175 MHz.

Each of the transistors features balanced-emitter construction for maximum safe operating area, isothermal design for flat power output versus temperature performance, and low lead inductance stripline packaging.



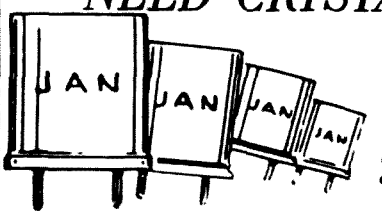
The transistors are designed for the 12.5V VHF large-signal amplifier amplifications required in military and industrial equipment operating at frequencies up to 250 MHz.

In the unusual construction used for the four new transistors, thin-film Nichrome resistors in series with each of the multiple emitters distribute power evenly throughout the chip. This technique prevents "hot emitters" and results in maximum safe operating area and a rugged device that

stands up under the high voltage standing wave ratio conditions sometimes occurring in a mistuned rf system.

The MM4020/21/22/23 transistors bring another important characteristic to the rf designer – exceptional output power stability versus temperature – through the use of isothermal design. This type of transistor design insures the even generation and flow of heat in and from the chip so that the "power slump" usually encountered in an rf power device operating near its maximum frequency is nearly absent. *Motorola Semiconductor Products Inc., Box 20924, Phoenix AZ 85036.*

Amplifier Modules in Semi-Kit Line



Eight different special and general-purpose audio amplifier modules are being offered by GC Electronics Division of Hydrometals, Inc., as part of its new Calectro-Amperex line. Basic module shown here is a 20-watt stereo amplifier, which is blister-packed and displayed on a pegboard rack. The line also includes lower-power hobbyists' amplifiers and guitar amplifiers, along with a professionally finished universal chassis/cabinet kit. *Ivens Stanton Assoc., 122 East 42nd St., New York NY 10017.*

Miniature FM Mobile Unit

The Regency solid state Model HR-2 features a 10W of rf power output with operation on any of 12 transmit and receive channels. The receiver section of the new radio is double conversion, superheterodyne with a highly selective ceramic filter for operation on both wide and narrow band signals. Sensitivity is rated at 0.35 μV, 20 dB quieting. The transmitter features phase modulation for exacting

NEED CRYSTALS?

We can supply crystals from 2KHz to 80 MHz in many types of holders.

SPECIALS

Color TV crystal (3579, 545KHz) wire leads	$1.60 4 for 5.00
100 KHz frequency standard crystal (HC 13/U)	4.50

carrier stability. Individual trimmer capacitors enable frequency netting for optimum performance in point-to-point or repeater applications. Built-in swr load mismatch circuitry protects against open or shorted antenna conditions.

The 2¼ x 5½ x 7½ in. package comes complete with plug-in ceramic microphone, built-in speaker, and mobile mounting bracket. One pair of factory installed transmit and receive crystals on 146.94 MHz are included in the $229 amateur net price. *Regency Electronics, 7900 Pendleton Pike, Indianapolis IN 46226.*

High Power on 450 MHz!

Requiring only 8–10W of rf input power, the Alpha PA-100 UHF amplifier will achieve a power output of 100W. Designed for fixed base station or repeater use in the 450 MHz band, this compact unit has a self-contained solid-state power supply, no electromechanical moving parts, and requires only 5¼ in. of rack space. The true integrated coaxial plate cavity construction assures high plate efficiency and low plate operating temperature, making possible continuous-duty use while assuring long component life. The grid input circuit works to suppress harmonics generated by the input transmitter, thus reducing the problem of intermod. The PA-100 is said to be easy to install and is ideal to upgrade existing low-power repeaters or base transmitters. *Alpha Electronic Services, 8431 Monroe Ave., Stanton CA 90680.*

High Power on 2 FM

The new "22'er FM" by Clegg features 60W of rf input power plus a highly sensitive TUNABLE receiver. Ten crystal-controlled channels are available for transmit. Made in the United States. *Clegg Associates, Inc., Littell Road, East Hanover NJ 07936.*

Solid State Transmitter-Receiver

Another 2 meter FM transceiver has just been introduced to the amateur scene. The unit sells for $250, has a 5W transmitter, 6-channel receive-transmit, FET front end. The i-f's and af circuits are IC, and the unit comes with two installed channels (.94 direct and .34–.94). A front panel meter indicates signal strength and rf output relative power. Price includes mike, bracket, and dc power cable. *Telecomm, Box 461, Cupertino CA 95014.*

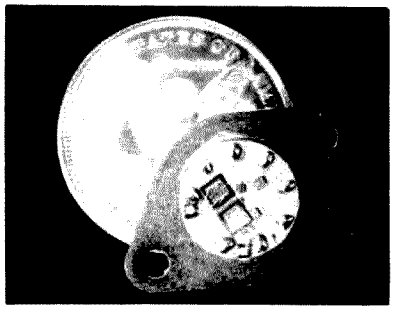
Phase-Locked-Loop Linear IC

Two new "phase-locked loop" linear integrated circuits are ideally suited for such applications as accurate multiplication and division of frequencies virtually in any ratio, according to *Arthur E. Fury, Manager of Linear Product Marketing.* Range of operation extends from subaudio frequencies to VHF.

"These units are unique in the industry," Fury said, "because they are designed to perform mathematical functions that are quite impractical with digital circuits. Our devices can multiply, divide, and even fractionalize frequencies virtually in any ratio. For example, they can divide a fundamental frequency by 10/3, if desired, a process which is virtually impossible with digital devices."

Operating range of the 562, a model of the device fabricated with a dielectric isolation process, is 0.1 Hz to more than 50 MHz. The 562 chip is 67 by 75 mils in size. Signetics engineers designed the two new phase-locked loop circuits in direct response to comments received on the first PLL linear circuits which were introduced by the company several months ago. "We have added a number of features," Fury said, "which makes the phase-locked loop more useful for specific applications. Most important among the features is that we have opened the loop and provided connections that permit the insertion of external devices into the loop circuit."

Four separate sections comprise each device: a phase comparator that also operates as a multiplier and mixer, a low-pass filter, an error-signal amplifier, and a voltage-controlled oscillator. The loop circuit has been opened between the VCO and the phase comparator.

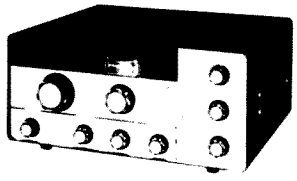


Additional information is available from *Signetics Corp., 811 East Arques Ave., Sunnyvale CA 94086.*

Low-Harmonic High-Power Linear

Raytrack Company of Columbus, Ohio is introducing its new lowband linear amplifier, the DX2000L. This amplifier has an input capability of 2 kW PEP SSB, and 1 kW AM, CW, and RTTY, and is for operation on the 80–10 meter bands. The DX 2000L is the first high-power linear amplifier to use a hybrid tank circuit (Raytrack's unique toroid and air inductor combination). This system gives the DX2000L extraordinarily high efficiency on all of the 80–10 meter bands, and, in combination with the pretuned toroid input makes this amplifier far less prone to radiate TVI, according to the manufacturer.

Two zero-bias triodes (EIMAC 3–500Z) are operated in class B and are preneutralized for maximum stability. Other features include: an adjustable alc output (negative feedback) that is compatible with all standard equipment; an exciter feedthrough that eliminates the need for additional relays to operate the exciter only; *precision* taut-band meters; and a very handsome case. The DX2000L has a separate power supply that is included in the price. *Raytrack Co., Columbus OH.*

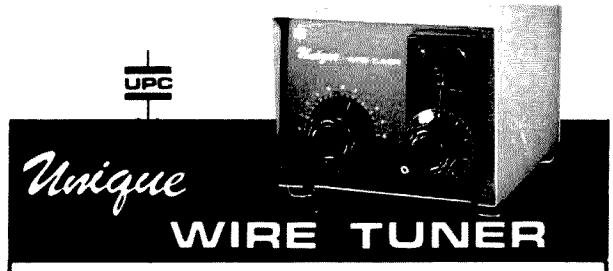


Hybrid Power Amplifier

TRW Semiconductors announces the addition of the HMD 2000 hybrid power amplifier to their microelectronic product line. This amplifier can be operated in either a linear or switching mode with capabilities of delivering 3A peak current for power supplies to ±25V. Mounted in a TO-3 package, it is ideal for a broad range of applications including switching; class B servo; hi-fi audio amplifiers, and motor drivers. Power amplifier is priced at $10.50. *TRW Semiconductor Div., 14520 Aviation Blvd., Lawndale CA 90260.*

SERVICE AND FRIENDLINESS
To Radio Amateurs For 32 Years
WE MUST BE DOING SOMETHING RIGHT.

RECEIVER TUNING OPTIONS **PHONE 518-842 8350**



The Clegg 22'er FM is now available with two RECEIVER TUNER choices:

Series 24: Full 2 meter band coverage from 143.4 to 148.3 MHz. Calibration is in 100 kHz increments and readable to 25 kHz.
Amateur Net Price of the 24 Series units is $369.95 with Transmit crystal for 146.94 and PTT microphone.

Series 25: Restricted coverage from 145.9 to 148.2 MHz with the tuning dial calibrated in 30 kHz "channel" designations.
Amateur Net Price of the 25 Series unit is $384.95 with the same accessories. The 25 Series units also include a steeper skirt ceramic filter in the IF stages.
ADDITIONAL TRANSMIT CRYSTALS can be furnished (.0005% tolerance from 1 to 40 degrees C ambient) at $9.00 each. All standard 30 KC increment channels are available in stock. Alternately, crystals can be supplied by Sentry Mfg. Co., Crystal Park, Chickasha, Oklahoma 73018. Order their Stock No. 88001 plus desired output frequency.

I shall never forget one Hallowe'en, long ago when I was a neophyte in electronics. My dear old grandmother, God rest her, came into the parlor ready to settle down with a good bloody murder mystery. It was quite late and the whole family, she thought, was sound asleep. She switched on the light.

"Good evening."

Grandma jumped back. Then, getting a grip on her nerves, she quickly checked the closet, looked under the couch and behind the curtains. She was quite alone in the room.

"What 'cha looking for?" It seemed to be coming from the coffee table. An old newspaper lay innocently on the table. Grandma adjusted her glasses, bent over the table and scrutinized the paper. She was breathing rather hard.

"Lady, you really ought to do something about those adenoids."

Grandma jumped back as if she had seen a rattlesnake. "It talked," she gasped, "The d——thing talked!"

"So, what's wrong with that? Do I get all shook up when you talk?"

Grandma was completely befuddled by now. The last remaining black hairs on her head had just turned snow white. Then a strange thing happened. She shrugged her shoulders, set her mystery aside, and began to talk. Of course she never told anybody about the conversation, but she confided with the newspaper that she hadn't had such an enjoyable conversation in ages. The two of them chatted together until the wee small hours.

I never had the courage to confess to Grandma that I had been the culprit. A few times after that, when she thought she was alone, she tried to strike up a conversation with other newspapers, but none of them were anywhere near as sociable as that Hallowe'en issue.

Since I've already mentioned that I had been the culprit, you've probably guessed that there was a loudspeaker concealed in the room. Not exactly. The secret really lay in the newspaper. If grandma had picked it up, she'd have caught on right away. Fortunately for me, she was far too polite to lay hands on her guest.

It's really a pretty simple thing to rig. All you need is a copy of the Daily Dirt and a package of aluminum foil. Open up a full sheet and spread a strip of the foil inside it. Fold the sheet over and lay another strip of foil on top. When you fold the sheet again, if you've done it right, the foil should be completely concealed and the paper should look the same as it did when it was on the news stand. The two pieces of foil should be insulated from one another by the paper. In other words, the whole business should look like a big capacitor. The next step is to wire it up, but before we do, let's take a look at how and why it works.

I said before that it is a big capacitor. I can qualify that slightly and say that actually it is an electrostatic loudspeaker. The

audio signal is impressed between the two foils. Since two oppositely charged objects attract each other, and since the audio signal consists of a varying voltage, there is a

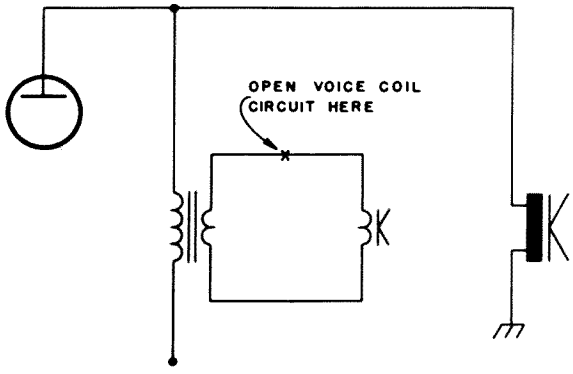

Fig. 1. Method of connecting electrostatic speaker to vacuum tube output.

varying attraction between the plates. The plates, in this case the foils, will therefore vibrate and reproduce the sound.

When I first rigged up this demonic device, solid state equipment was virtually unheard of, so I simply connected one foil to the plate of my final amplifier tube, and the other to the chassis. Electrostatic speakers work best when the audio is riding on top of a high dc voltage. This polarizing voltage, as it's called, was neatly provided by the plate supply voltage which was there anyway.

Nowadays most audio equipment is solid-state. Since solid-state operates under very different conditions, you will now have to artificially duplicate vacuum tube conditions. An electrostatic speaker, you see, is a very high impedance device, and so it must be fed with a high voltage signal from a high impedance source. You can meet this requirement by connecting a small output transformer in reverse. That is, the voice coil winding connects to the output terminals of your amplifier. The plate winding connects to the foils. A polarizing voltage of a hundred volts or so can be supplied either from a rectifier or from a battery, the capacitor, C, providing a path for the audio voltage.

REGENCY

an FM Late Starter

. . . could be a front runner!

Ken Sessions K6MVH

I have nothing but praise for Regency's new HR-2 miniature multichannel all-transistor 2 meter FM transceiver. This is far and away the best buy in American-made amateur FM units. It's priced right, it performs right, it has a very respectable output power, and it is one of the smallest units obtainable. And it has some very desirable features that none of the other manufacturers have thought of yet.

Of all the good points, the price itself is the most impressive. At $229 there should

Manufacturer	Model	Price ($)	Channel Combinations Available	Total Xtals T	Total Xtals R	Mfr Loc	Xmtr Pwr Out (W)	Rcvr Sens (μV - 20 dB)
Regency Electronics	HR-2	229	12	6	6	U.S.	10-12	0.5
Galaxy (Hy-Gain) (w/power booster)	FM-210	230	9	3	3	U.S.	2.5	1.0
Telecomm	FM144-10F	250	6	6	6	U.S.	10	0.5
Varitronics (Inoue)	FDFM-2S	270	6	6	6	Jap.	10	0.8
Standard	SR-C806M	349	12	12	12	Jap.	10	0.5
Varitronics (Inoue)	IC-2F	349	36	6	6	Jap.	12-15	0.4
Clegg Associates	22'er	400+	Tunable	10	0	U.S.	30	0.4
R.L. Drake Co.		329	12	12	12	Jap.	10	0.5

be no reason at all for any VHF enthusiast to put off going to FM any longer. You're just not going to get on 2 meters FM in style for anything less.

Now let's take a look at what you get for that $229:

How about power? The Regency HR-2 runs between 10 and 12 watts *output*. The Motorola transistor that the Regency unit uses in the final rf amplifier is guaranteed to crank out at least 10 watts, and the people at Regency are making sure that each unit produced meets or exceeds that specification.

Deviation level. When the Regency leaves the factory, the deviation is set at 10 kHz. Since this is a little much for the New England repeaters, I had to crank our test model down to about 7 kHz. The deviation can be adjusted anywhere from less than 5 to slightly more than 15 kHz with an easily accessible pot inside the rig. The unit comes with microphone, too, by the way – and from reports of the local repeater groups, the audio is exceptionally clean.

What about the receiver? The receiver is a dual-conversion superheterodyne type with six-channel capability. It is relatively broad-banded, requiring no peaking on individual channels in the 2 meter range. A ceramic filter in the second i-f stage gives adequate selectivity for most metropolitan areas, even where adjacent channels are active.

If you buy this rig and later decide to add crystals, you've got to be a bit choosy as to where you buy your rocks. The HR-2 has no means of rubbering "receive" crystals onto frequency; if the crystals are off, your receiver will be off. The people at Regency say nobody will ever have trouble if they order from Sentry Manufacturing Company (Oklahoma), International Crystals (Oklahoma), or Shepherd Industries (Kansas). To my mind, the lack of

Accessories Included in Purchase Price	Extras You Must Buy	Comments, Special Features	Problems, disadvantages
Microphone, power cord, mobile mounting bracket, crystals for 146.94.	None	See text	No meter; no receiver rubbering capacitors.
Power plug.	ALL	Power booster supplies 24V dc to final transistor to bring the rf output up to 5W. (costs $50 extra).	No accessories, no meter, unstable rubbering capacitors.
Mike, mobile mounting bracket, power cord, crystals for 146.34 and 146.94.	None	Panel meter for rf out & signal strength.	Test unit did not meet specs.
Mike, mobile mounting bracket, power cord, crystals for 146.34 and 146.94.	None	Illuminated panel meter for rf out & signal strength in.	Antenna connector makes sloppy fit to VHF connector.
Mike, mobile mounting bracket, power cord, crystals for 146.94.	None	High/low power switch; illuminated panel meter. Add-on amplifier avail.	Squelch and volume controls too tiny for easy mobile operation.
Mike, mobile mounting bracket, power cord, crystals for 146.34 and 146.94, antenna connector, spare fuse, connector for optional external speaker. Discriminator test socket and plug.	None	Panel meter illuminated white on rcv, red during transmit. Meter indicates S-units and rf out. Freq selector switch is concentric so xmit and rcv channels are independently controlled.	
Ac/dc power supply, microphone, power cords for ac and mobile operation.	None	Built-in ac/mobile power supply.	Tunable receiver. Too large for mobile use. Tube-type transmitter final.
Mobile antenna, coax, mobile mount, mike, ac/dc pwr splys.	None	Built-in ac/mobile pwr supply. Extremely selective & stable rcvr.	Transmitter has vacuum-tube final.

Amateur Test and Measurements by W5REZ..... $5.50
Using VOM, scope,VTVM, dipper, SWR bridges, etc. Covers amateur uses of test equipment in the ham station. 208 pages, softbound. Interestingly written, covers tuning receivers, all kinds of transmitters, etc. Invaluable for every hamshack.

Electronics for the Amateur by W5REZ .. $7.95
Hardbound book, 272 pages. Covers entire theory needed for passing amateur licenses. Fine book for instructors, and for amateurs wanting a refresher course before exposing themselves to the FCC examiners. Hardbound books look nice and last.

Handbook of Transistors, Semiconductors, Instruments and Microelectronics by Thomas..... $14.50
453 pages, hardbound. For the working engineer, circuit designer and technician. Very thorough. Limited supply. Published at $25.

IBM Electronic Circuit Analysis Program By Jensen. Hardbound, 400 pages, published at $25, limited supply at $9.00.

Radar Detection by DiFranco. Hardbound, 654 pages, published at $20, limited supply $8.00.

Audio Systems by Crowhurst .....$7.95.
Audio for the engineer, the hi-fi addict, and the broadcast engineer. Every radio station should have this handbook handy.

Electronics Reference Handbook Hardbound..... $7.95
All the charts, tables, formulas, and other reference data that you need as a technician, ham or engineer.

TV Servicing Guidebook, hardbound $6.95
This is a book on isolating the circuit containing the TV defect, not a theory manual. It should help you get those sets moving.

Electronic Test & Measurement Handbook Hardbound..... $7.95
Use of various test instruments. Testing transmitters, receivers, amplifiers, etc. Covers subject thoroughly.

The Man Behind the Mike, hardbound $6.95
Guide to radio announcing for the professional.

Tape Recording for Fun and Profit Hardbound..... $7.95
Complete data on recorders, systems, mixers, microphones, cassettes, etc. Much money to be made in this field.

Single Sideband: Theory and Practice Hardbound..... $6.95
W6TYH handbook of basics and circuits. Complete analysis of all ssb equipment.

FM Repeater Handbook, hardbound $6.95
K6MVH. Book is required for all repeater operators and must reading for all FM'ers. Only complete book on the subject. It is also one of the best selling books in amateur radio today.

Editors & Engineers RADIO HANDBOOK Hardbound..... $13.50
Latest (18th edition) by W6SAI. This is the most complete ham handbook ever published. Makes all other handbooks look like comic books. 896 pages.

Editors & Engineers RADIO HANDBOOK Hardbound..... $10.00
W6SAI (17th edition) reduced for clearance, limited supply available for fast acting amateurs. Last chance to get this great book before it is gone forever.

How To Fix Transistor Radios & Printed Circuits Only..... $7.95
Do you throw those little radios away when they stop? Wasted money! Easy to fix with this manual. Worth many times the low price. No serviceman or amateur should be without this tremendous book.

125 One-Transistor Projects, hardbound .. $6.95
Practical circuits for the experimenter and hobbyist. Have fun building these 1-transistor circuits...test instruments, audio amps, oscillators, receivers, transmitters, alarm devices, etc. Never will you have so much fun for so little.

RADIO BOOKSHOP

73 Vertical, Beam and Triangle Antennas, . $4.95
W3FQJ. If you like to build interesting antennas then you will seriously regret passing up this wonderful book. Also info on noise bridges, other test equipment you can make and use to advantage.

73 Dipole and Long Wire Antennas $4.50
W3FQJ. Better buy both books. Includes all dimensions, details.

Installing & Servicing Home Audio Systems $7.95
Hardbound, 256 pages. Worth its weight in gold. Positively the finest book ever written on the subject. Make a fortune in part time audio work. Hi-fi is everywhere and none of them are working right.

64 Hobby Projects for Home and Car Hardbound..... $6.95
Any one project is worth more than the price of the whole book. Light sensitive garage light, wireless TV commercial killer, fire alarms, smoke alarm, etc. If you are having less fun in radio you aren't building enough small projects. This book is guaranteed fun.

CB Radio Operator's Guide, hardbound .. $6.95
Most complete book ever published. Lists all equipment and antennas available, all accessories...how to use them, how to set up, test, get best action. Contains complete CB rules and regs.

Servicing Modern Hi-Fi Systems by Crowhurst..... $7.95
Hardbound. Paperback is only $4.95, but won't look as nice on your shelf or last as long. Those solid-state hi-fi's bugging you? Like duck soup with this gem of a book. Why take hours to find miseries when you can take this book and pin-point difficulties immediately. This book will either save you a fortune or make you one.

Basic Electronics Problems Soved, Smith .. $7.95
Hardbound. Paperback is only $4.95 if you don't care how your library looks. Solid state and tube circuits. This is a "cheat book" which will whiz you through any electronics course by showing you short cuts in solving electronics problems and math.

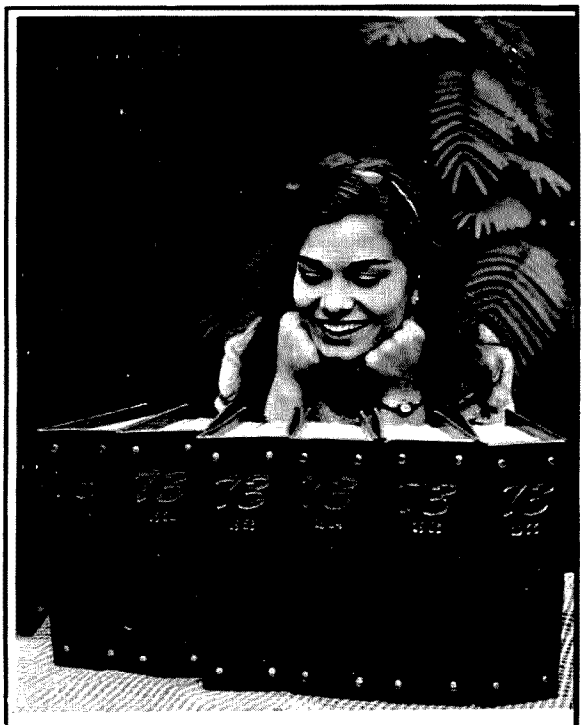
Modern Electronic Circuit Design by Long $9.95
Hardbound, 286 pages, McGraw-Hill. Written for professional circuit designers, graduate engineers. Published at $18.95. Looks very impressive on the reference shelf. Worth many times the price as prestige book. Also handy if you happen to be an engineer. Limited quantity on hand. Hurry.

Handbook of Practical Electronic Tests and Measurements, Lenk. Hardbound $9.95. Published at $18. A guide to the basic theory and application of every practical electronic test and measurement procedure for technicians and amateurs. Limited supply so act fast.

Pulse and Switching Circuits, hardbound .. $7.95
Almost ev ery phase of electronics uses switching circuits...TV, radar, telemetry, computers, etc. About time you read up on every one of these circuits being used, isn't it? 256 pages, over 200 illustrations. Available paperbound (falls apart) for $4.95.

FM Receivers by Cook Hardbound, 528 pages..... $14.50
Published at $25. Most comprehensive book ever published, absolutely up to date... all circuits. Invaluable for professionals and advanced amateurs.

Amateur Radio Advanced Class License Study Guide..... $6.95
Hardbound book for your library shelf. 193 pages! Absolutely everything you need to know to pass this license exam, written by one of the top radio editors in the business. Written for the simple-minded so they can pass the exam by knowing the answers instead of memorizing them. This book is available in softbound for $3.95. You are going to have to get an advanced license so you might as well get this book right now.



Electromechanical Devices for Energy Conversion and Control Systems, by Del Toro
Published at $25. Limited supply at $10. Hardbound, 617 pages.

tweaking ability on the receiver is a distinct disadvantage – but it is overshadowed by a considerable margin when I consider the unit's sales price.

Special features? The most useful single feature of the HR-2 is its multiplicity of transmit–receive combinations. There are six crystal positions each for the transmitter and the receiver, but a twelve position switch is used for selection. The first six positions on the switch (numbered 1 through 6 on the faceplate) select the six crystal positions, and the next six positions on the switch (labeled A through F) can be used to select specific combinations of the various crystal sets. Positions A through F are chosen by jumpering on the switch itself, so that there are a total of 12 available channel sets from only six sets of crystals.

How does the Regency HR-2 stack up? Probably the best way to determine the relative merits of the HR-2 is to compare the unit with other 2 meter FM transceivers. The chart on the preceding pages will give you an opportunity to make your own comparison and evaluate the features you consider to be the most important.

World's Finest Log Book?

Designed and executed by W2NSD/1, this is the most relevant amateur radio log ever designed. This is a log for today. It has a column for the date, one for time and off of each contact, a small column to indicate whether you called the station contacted (or CQ) or not, a good wide space for the station call contacted, little columns for the reports, a good space for his location, a QSL column, and lots of room for notes. The log is the long way on standard 8½" x 11" paper and padded into pads of 125 sheets, with room for 20 contacts per page. The whole book of log sheets will carry you through 2500 contacts. There is a place to indicate on each sheet the band being used and the power in case these change now and then. The log pages can be numbered for file card reference. Why use a log book designed in the 1920's? This one was designed for use in the 70's and is exactly right for the DX'er, the rag chewer, or even the round-table denizen. It is fine for CW or phone, AM or sideband. It will work for RTTY, ATV or even slow scan television. Never has a log been made available which is as handy as this gem. Why keep struggling with those ring binders which get all bent out of shape? Get this first really modern log.

125 Super W2NSD log sheets. . . .only $2 ppd.

Transi-Test

Of all the various transistor tester projects that have appeared in numerous amateur radio and electronic magazines this past decade, I believe I have come up with a circuit that will outdate previous articles. Many of these projects have been designed so you may utilize a tester with your scope, VTVM, or some other gear.

This particular circuit, which I named the "Transi-Test," is designed with simplicity and is very accurate in measuring beta, leakage, and shorts. It will test any NPN or PNP transistor (signal or power). I also find it great in checking silicon or germanium diodes by using the emitter and collector leads to test for shorts and leakage. The Transi-Test is 100% portable, using a 9V battery for its power supply.

Most transistor testers employ a 4pdt switch for polarity, but this one is designed around a dpdt switch, which is easy to find at any parts store. To say the least, all the parts can probably be found in your own junkbox! I used a Premier #SPC-23 meter case to give the Transi-Test a professional appearance. The three test leads should extend 6 to 8 in. from the front of the case. For easy connection to small transistors, a micro alligator clip should be used such as the Mueller #34-C. Be sure to use an alligator insulator on the collector lead to prevent the emitter and collector leads from shorting together due to stiff test leads. This will save unnecessary battery failure.

If you do transistor servicing quite frequently, it is advisable to use a toggle switch (S1) which will last indefinitely. The only holes that have to be drilled in the case are for the three test leads, using rubber grommets. The SPC-23 meter case is already prepunched for the meter and two switches, which is why I happened to choose this particular one. Bud Radio also manufactures a case identical to this one.

After completion of this small project, you can rummage through your junkbox and start identifying those "lost cause" transistors that have been lying dormant all this time. I'm sure you will find the Transi-Test to be a very valuable test instrument on your workbench.

Lew Christy WB6QQP ■

Never Say Die *(cont. from p. 10)*

been a strong factor in freezing the League into immobility. We cannot afford this paralysis in the 1970s. If directors were to attend four regional ARRL conventions each year (east, midwest, southwest, west) and consult the membership at open forums at these conventions, they could act immediately upon the wishes of the members. Their way would be paid to the four conventions by HQ.

Public Relations

A competent public relations firm (preferably run by an amateur) should be engaged to promote amateur radio with articles in national magazines such as Life, Look, Newsweek, Playboy, etc. They could coordinate amateur radio talent such as writers, cartoonists, and performers for maximum effect. They could help to organize ham films for television, for schools, and even shorts for movies. They could prepare strip slide shows for schools and libraries. They could prepare news releases for the papers and news services, thus making sure that amateur accomplishments reached the television, papers, and radio.

Club Material

In order to increase interest in radio clubs throughout the country the ARRL should have a wide variety of films available, covering all aspects of amateur radio operation...contests, DXpeditions, moonbounce, television, RTTY, traffic nets, mobile operation, repeater operation, etc. There are many amateurs that would be happy to work to produce films and slide shows on amateur radio subjects if only there were a central organizing effort. ARRL could provide this coordination. Films and slides can do a lot toward building club membership as any member of sports car clubs and skin diving clubs, will tell you. Amateur radio is almost alone in its lack of interesting program material for clubs. This should be a function of the League. Who else *is* there?

Outgoing QSL Service

Virtually every other national amateur radio society in the world provides an outgoing QSL service for its members sending cards to other countries. There are, as far as I know, no insurmountable problems stopping the League from providing a similar service. This should be carefully investigated from the viewpoint of finding out how to do it rather than trying to find out why it can't be done.

Legal Fund

The legal problems involved in setting up an emergency fund for helping amateurs fight lawsuits which, if lost, could seriously affect the whole amateur radio hobby should be investigated and overcome. Is there any real reason why the League should not help beleaguered amateurs in such legal fights?

Amateur Radio's Future

Satellite repeaters for FM and ATV are within the realm of technical feasibility today. The League should take the lead in planning for the future of our hobby. Even the cost of a set of satellite repeaters covering the whole world could be organized by the ARRL. Perhaps the techniques of multiplexing can be developed and applied to solve QRM problems on 20m and other crowded bands. Dialog in QST on new ideas should be encouraged.

Radio Clubs

It is possible that the role of amateur radio clubs could be expanded in the administering of exams for the FCC.Certainly the clubs could be a powerful factor toward developing new amateurs with guidance and encouragement from HQ. A monthly newsletter to provide dialog between radio club presidents and the directors might help encourage amateurs to take more interest in their future.

IARU Development

The International Amateur Radio Union, made up of the national amateur radio societies of the world and organized by ARRL could function better and provide better leadership if ARRL were to publish a monthly newsletter for all member societies. At present all that is provided, I understand, is a yearly calendar. Region 1 (Europe and Africa) periodically publishes newsletter. The amateur radio societies in the rest of the world might have more confidence in IARU if it provided some leadership and communications.

The IARU could spearhead a drive to collect older amateur radio equipment and ship it to underdeveloped nations. The shortage of equipment is one of the most important deterrents to new amateurs in these countries. India could have thousands of amateurs instead of a few hundred if only gear were available.

Unity of the IARU societies would provide unity toward the problems of the ITU and frequency allocations. Communications is the first step towards unity.

New Books

The ARRL book department should be turned upside down and cleaned out. One look at the Editors and Engineers handbook is enough to prove that a major change is needed in the production of books at HQ. The yearly ARRL Handbook changes like a glacier. Not only that, but one of life's more frustrating experiences is to try and learn radio theory from that book. This is not necessary as we showed with our license study courses.

Spend 25¢ and buy a copy of the ARRL book on "Operating an Amateur Radio Station." This publication is all too typical of League literature and is beyond description. As a director I would make every effort I could to see that those re-

sponsible for this type of claptrap were transferred to some other job.

The League has a responsibility to produce interesting and up-to-date books on every aspect of amateur radio. They should have thorough study books on each amateur exam, not memorization manuals as they do right now. They should have a definitive and continually updated book on RTTY, DX, ATV, FM, moonbounce, traffic, VHF, learning the code, high-speed code, frequency measuring, 160m, antennas, microwaves, etc.

QST can carry information on building gear, on new developments, and such, but books are needed to provide detailed information on specific interests. Obviously these would all pay for themselves.

New General Manager

Few amateurs with whom I have talked have had anything encouraging to say about their visits with the present ARRL manager. Though I don't talk with him often, I must admit that on each occasion I have found him to be as close-minded as the visitors have reported. If he were capable of doing his job we would not have the growing problems here and all over the world which he has brought upon us.

Were I to be elected a director I would try to get the other directors to start looking for a suitable manager for ARRL.

It would not be simple to find the right man for this difficult job. There are many qualifications that he should have to be worthy of consideration. But you may be sure that such a man exists and that it is important that he be found before it is too late.

What sort of man do we need for this post? As I see him, he should be a man who has devoted a good deal of his life to amateur radio. He certainly should have a record of being interested and active in several branches of the hobby...DX, TV, RTTY, VHF, FM, traffic, etc. I would expect that he has done a good deal of building and designing. I would think it strange if he had not had several articles published.

The ARRL is a $1,500,000 business, so we should expect our man to have experience in running a medium-sized business. One of the problems at HQ is mismanagement of finance. There is no shortcut to business knowhow.

Our manager is also the editor of QST, so some background in publications would be valuable. He will need this to help cut the present runaway costs of publication of the magazine. Of course he could learn about all this after being hired if you like the idea of on-the-job training at your expense.

Our man should be able to speak well in front of large groups. The general manager is also a front man for ARRL and must attend most ARRL functions as host. He would also be expected to speak for the United States at international gatherings and at the ITU.

One would hope that the manager of the ARRL was highly intelligent. Can we afford to have a mediocre brain at the head of 265,000 U.S. amateurs? And remember that he is the titular head of amateur radio worldwide. This spot calls for all the brains we can muster.

I suspect that we should also be sure that the man we choose is one with a long history of getting things done. A man's history speaks for him. If he is too wealthy he has devoted himself to wealth alone and not to other interests. Has he a wide number of accomplishments? Is he well read? Will he be interested in working for a modest salary with his major payment in achievement? The answer is simple, of course. If you ask any director of any large corporation how he goes about finding a new general manager, he will tell you that there are a number of organizations that specialize in just that. You consult one and let them find your man.

Most of the directors that I have talked with recognize that it is important for them to locate a new general manager, but they are afraid to take the bull by the horns.

Other Ideas

This is by no means the end of my ideas for improving the ARRL, but I have probably lost 90% of my readers already and should shut up. Now that I've told you some of the things I would try to do if I were elected director of the ARRL, perhaps you can encourage your own director to go ahead with some of them. Or you can work to get a director elected that will do what you want.

73 at Boston

The ARRL National Convention hit Boston in the fall this year, providing a splendid display of New Hampshire foliage for those interested in beauty.

When I got word from the convention committee that no one from 73 would be permitted to speak at any convention function, I made arrangements to hire an auditorium room in the hotel to provide forum space for those interested in FM, repeaters, ham politics and my slides of Jordan taken just before the civil war there.

In 1969 we took along an international Crystal microwave oven and cooked some New Hampshire hotdogs as a feature of our exhibit. This was popular, but I didn't want to repeat so we decided to have some freshly squeezed New Hampshire apple cider along with fresh home-made New Hampshire donuts this time.

On the Friday afternoon before the convention we went up to Hancock (N.H.) and helped Joe Quinn run off almost 30 gallons of the best apple cider you ever tasted. Early Saturday morning we stopped by Crane's Bakery in Jaffrey (N.H.) and picked up 73 dozen old-time New England donuts. None of those machine-made crullers for us! There wasn't a really round one in the bunch.

We served the cider and donuts all day Saturday in between slide shows, forums, and talks in our auditorium room. By the way, one really outstanding show was put on by George Pataki YO2BO, showing slides of visiting DX hams and his recent visit to DX'ers in Europe.

To those who have written to thank us for the feed and the programs, we hereby acknowledge your notes and want you to know we appreciate your thoughtfulness.

A Look Around 73

In looking at last year's staff picture we see several absentees, alas. Two of our gals left to get married, and a third left to work with her husband who started his own business.

We've had some interesting replacements for the dear departed, starting with Nancy, who was with us back in early 1970, but had gone off to seek her fortune in Colorado, and returned, she's not sure why. Nancy puts together most of the ads in each issue as well as laying out many of the articles. Jan, the other gal in the art department, does most of the rest of the articles. In her spare time Jan is an outstanding artist, joining Lin out in the 73 art studio afternoons and weekends.

Ken Sessions (K6MVH) has added a new dimension to the editing of 73, as well as an almost undetectable tendency to favor FM articles. Ken is responsible for the new arty look of the articles in 73.

Taylor Sage joined us recently and does just about everything that we can't get anyone else to do, from supervising the maintenance of the HQ building to keeping our recalcitrant machinery running. His wife Gigi handles the bookkeeping.

In our print shop we have Jeff Parsons and Biff Mahoney, who run our three offset presses, turning out local job work as well as office forms, advertising letters, and stuff like that. 73 is printed in Wisconsin, not here, but we do have complete facilities for smaller printing jobs and turn out our books right here.

Nixon Letter Reprints

Several clubs have called and written asking for bulk copies of the October 73 Action Coupon addressed to President Nixon. This coupon requests an investigation of the recent increase in license fees for radio amateurs. If you would like reprints of this page just send a self-addressed stamped envelope to 73, Peterborough, N.H.03458 and indicate how many reprints are desired.

Ham Bumper Stickers?

Several readers have suggested that bumper stickers be made available for amateurs. Since we have dandy facilities for printing up bumper stickers here at 73 we are all for the idea. But what do you want on the stickers? We are open for any clever suggestions. The only sticker we have seen so far is BAN THE HAM, and that doesn't seem appropriate.

73...Wayne■

Leaky Lines *(cont. from p. 14)*

season, but who lapse into a state of sudden paraplegia when any mention of the FCC examination is made. They remind me of some unnamed soldiers of my acquaintance, who, never having served overseas in World War II, wore some unauthorized ETO, Asiatic Theatre, Persian Gulf Command or Purple Heart ribbons on their tunics when they went out on dates with young and impressionable (or old and impressionable) females.

I know that I am running the risk of falling into disfavor with the 35,000 odd Conditionals when I say this, but I feel strongly that some changes in this situation are long overdue. Perhaps I am being unduly harsh toward the Conditionals, but ever since the implementation of Incentive Licensing, I think most of us tend toward a less permissive and less tolerant attitude concerning all "something-for-nothing" advocates.

I am already considered *persona non grata* among large numbers of Techs who objected to my published views with respect to the granting of a portion of ten meters on an exam-free basis. They labeled me with every pejorative in the book, and with a few even I had never heard before. And I suspect that this new call to sanity will place me squarely in the path of the "slings and arrows of outraged Conditionals." So be it. Might just as well be hanged for a sheep instead of a goat.

I truly believe, and I am confident that many share my view, that all classes must somehow be drawn into the vortex, the mainstream if you will, of the present context of licensing. Operating a ham station is a privilege, not to be taken lightly. Any preferential exceptions to the standards which are now being demanded (intermediate in difficulty though they may be) constitutes a very real disservice to all those who have been compelled to upgrade in order to maintain their allocations. Unless all amateurs are governed by identical rules and regulations, subject only to *legitimate* exceptions for *valid* reasons, the entire Incentive Licensing structure becomes an empty mockery.

Simply stated, I am calling for the abolishment of the Conditional class license. Now, hold on a minute . . .I didn't say I was calling for the delicensing of Conditionals, but merely for the retirement of the category. I have thought for a long time that the designation "Conditional" implies by its very name a type of second class status, carrying a certain stigma with it. Since the privileges of the class are identical with the General ticket, the only reasons why it is maintained are: (1) the holder is physically handicapped, or (2) he lives in an area so far removed from an exam point that a journey thereto would consittute an unreasonable hardship, hence has not taken the customary FCC administered exam. He has, however, attested to his proficiency in the required tech-

nical elements, by taking an exam by mail, supervised by a volunteer examiner. In all other respects the grade of license is not distinguishable from the General license. Why then must he be given this appellation "Conditional"?

An apt analogy is that of native born citizens and naturalized citizens. Both are entitled to exactly the same rights and privileges. Both are expected to shoulder the same obligations and responsibilities. No one asks a citizen whether he is native born or naturalized. He's an American citizen, and that's that! Another case which comes to mind, unfortunately still not expunged from American life completely, is the regrettable holdover from the unspeakably horrid days of Puritanism, when the innocent and blameless offspring of unmarried parents were stigmatized with the label of illegitimacy. Though they were not different in any way from others, they were regarded as inferiors, and because of this barbaric practice, were denied status in society in an unbelievably broad spectrum of areas . . .jobs, education, social acceptance, marriage, civil service, freedom from the mischievous, wagging tongues of the vicious hypocrites who enjoy making others miserable at every opportunity.

Let us grant that the mail exams have been on the up and up . . .that not a single Conditional was party to any hanky-panky. Despite this concession, there will always be those who will wink, place their fingers alongside of their noses and nod knowingly. So long as someone wears that designation on his sleeve he is fated to be suspected of having cheated. Since we have just finished granting that such is not the case, and since all the Conditionals have applauded my eminent fairness with enthusiasm, the next logical step would be to require some of them (just a few . . .75%, for example) to prove that our utter confidence in their integrity was well merited. Boy, I can hear the gnashing of teeth and the blue vitriol ascending into the air right now, really I can.

Why in the name of Tophet cannot some machinery be devised for the purpose of *taking the exam to the applicant* who cannot come in under his own steam. If a single volunteer examiner is regarded as untrustworthy, why not employ the services of (if you will forgive a Russian term) a 'troika' . . .three people are hardly likely to risk any joint dishonesty for fear of subsequent disclosure. They could undertake to administer the test to the truly handicapped person who cannot possibly get to the examining point. And the exam should be given the same weight as the regular FCC exam, with all credits applicable for higher grades. This should be limited to absolute establishment of the candidates' inability to get to the FCC office. All others should be required to meet the standards that have been established for the upper three license grades. If necessary, as seems likely, some of the additional revenues now being reaped from the increases in renewal fees (up 125%) could be applied to the establishment of additional exam centers, and could be used to help defray the salaries of additional personnel. Then, when the test is taken, either by the troika method or the FCC method, let the applicant be issued a General class license, completely indistinguishable from others, destigmatized and totally immune to the jibes and insults of any "first-class" amateurs who might feel an inclination to accuse them of skullduggery.

The fact is that we cannot, in good conscience, permit a large number of operators, comprising literally thousands of individuals, to continue to enjoy a privilege which is *earned* by the vast majority, simply by feigning physical disabilities which, in far too many instances, exist only in their wishful imaginations. We cannot continue to tolerate equality of participation by those who waltz blithely through the mile-wide loopholes of the law, which conveniently allow them to take the ticket while ignoring the basic technical requirements. No matter how sorely handicapped an individual might be, he should at least be required to conform to a standard within the limits of his own ability and competence. To offer him a completely free pass, an Annie Oakley, is not only derogatory to the rest of us . . .it is an insult to the integrity of every single Conditional with a legitimate reason for holding that grade . . .and there are many, many of them.

I am sure that we all know sightless hams, amputees, victims of dread disease, shut-ins . . .who have spurned the Conditional license, and who have insisted upon being examined in the standard fashion, just like everyone else, in order to avoid being deemed cripples or invalids. We are all mighty proud of them, for they are a source of inspiration, and their achievements set an example of courage for all of us. Within the framework of that type of pluck and determination, how can we possibly dare to countenance the flimsy alibis and "plea-copping" of the indolent, unindustrious, shallow cheats who masquerade behind the technicalities of legalistic gobbledegook, even though it may be within the definable semantic terms of the FCC regulations?

Isn't it time some changes were made?

* * *

I never saw the beat of it; when you write comment, many people take it as a personal point of privilege to challenge you on everything . . .opinion as well as fact. It is as though an editorialist had no right to express his own ideas . . .that somehow when he allows his name to appear on the printed page, he must express only that which coincides with what *they* think . . .all other ideas become invalid!

Really, you have no idea of the tone of reproof, sometimes downright abusive, which

even one's best friends are likely to use in disagreeing with this or that editorial point of view on any given subject. Take the recent growth of lists on the DX bands, for example. This has now become the chief target for the rugged individualist types who keep insisting that they prefer pileups.

I have no axe to grind either way. I have such a minuscule number of DX credits, that I'm happy to take 'em any way I can get 'em. So my views are not subjective . . .not based upon my own needs . . .therefore unprejudiced.

While it is perfectly true that a well operated station using standard power, a medium height tower and an ordinary tri-band antenna, is adequate in the average hurly-burly of a minor or medium-size pileup, it is decidedly at a disadvantage in the prodigious traffic jam which inevitably occurs whenever a rare one turns up. The recent operations at ZA, AC3, KP6, ZK1, and Gus Browning's Indian Ocean activities all demonstrated the folly of attempting to compete on an equal basis with the super-kilowatt boys with the sophisticated antenna systems. Those boys stick out like a sore thumb . . .many "dB" stronger than the other hundreds of poor shnooks calling in the pileup.

In such cases, the list method tends to favor the less powerful stations, enabling them to make QSOs which they would have very little hope of getting under normal circumstances. Of course, this displeases some of the big noises, who evidently feel that they do not wish to lower themselves by soliciting anyone's aid for the demeaning purpose of standing in line to make a contact . . .any contact. They seem to think that they should not be required to wait in line, but should be accorded instantaneous and undivided attention by whomever they call. They are perfectly willing to have everyone else stand in a long queue, twiddling the thumbs, just so long as it is not they who are made to wait. And whenever these certain parties hear a list operation in progress, a couple of them invariably try to break right in and call right on top of everybody, simply because they are just not about to get used to waiting their turn. When they are asked to move off because the DX is working to a list, they commence lecturing all and sundry on the evils of lists, and how this is likely to destroy amatuer radio. Or, they move off about two kilohertz and QRM the frequency with all of their side hash.

If ever there was a sterling reason for me to feel kindly disposed toward the lists, this would be it. I think that it is high time that some of these super-mouths on the bands were made to feel a little less secure about their positions on invincibility. It's time somebody gave them a comeuppance.

Well, anyway, to get back to the lists . . .I decided that maybe I would support a couple of them, not just to get in on the DX, but because I happen to be a strong advocate of their sponsorship of DX stations by distributing gear to them. So, I sent in a few bucks . . .not a large amount at all, and I had the unmitigated temerity to announce the fact on the air to a few fellows I know. Boy! That's when the eggs hit the fan! They wouldn't even control themselves to the extent of waiting their turn to tell me off. They said I was stupid, shortsighted, foolish, naive, ignorant, radical, vicious, treasonable, and that I was losing my marbles. They doubled, tripled, and quadrupled, drowning each other out in a cacaphony of indignant outrage.

Well, if there's one thing I've learned since beginning this column, it is this: Whenever you get an angry reaction as a result of something you've written, you can be pretty sure you're on the right track! Nothing gets people who have enjoyed an advantage (particularly an unfair advantage) more upset and riled than a movement toward equalizing the situation.

Of course, even if the edge could be taken away, they would somehow find a way to regain it. I know a couple of guys who would do it legally, by developing more efficiency in the antenna system, and that's fine with me. But the answer for many of them . . .far too many . . .would be an illegal increase in power. Don't ever get the idea that the so-called California kilowatt is confined to the Golden State. The overpowered stations are all over the map, and what's more, everyone knows it. And as long as there are people who are willing to sidestep the regulations by running illegal power, then I am solidly in favor of list-taking, because it is just about the best way yet devised for overcoming the overwhelming odds which have been unfairly lengthened by these cheats and chiselers.

MAGNETIC CAR SIGNS

W2NSD/1

$4.00 postpaid!

Put this magnetic call sign on your car when you are on a trip and meet the hams along the way. Comes right off when the XYL drives the car, if she doesn't want to be bothered by hams tooting at her.

Send $4 along with your call letters today. Radio Bookshop, Peterborough, N.H. 03458. (USA only please).

TWO-TERMINAL CURRENT LIMITER

Gerald Beene
Greenville TX 75401

Many power supplies will not survive a short circuit. The reason for this is that in the low voltage supplies used for

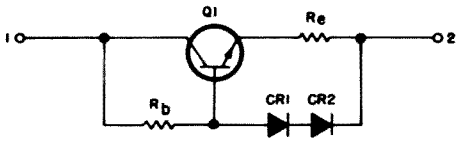

Fig. 1. Series current limiter circuit.

transistor circuit work, a series transistor is used to regulate the output voltage. If an unusually large current is demanded from the supply, and there is no current limiting,

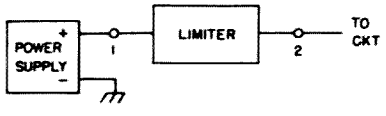

Fig. 2. Block diagram of limiter in typical application.

the peak current rating of the regulating transistor may be exceeded.

Other than the sensitivity of some power supplies to overload, experimental circuits are also subject to damage if for some reason excess current is allowed to flow.

A fuse alone will not necessarily provide the needed protection for current sensitive semiconductors.

The simple two-terminal current limiter shown in Fig. 1 will give instantaneous limiting for those slips of the probe, sudden shorts, etc. The use of a fuse in series with the limiter will reduce the need for a heat-sink on the transistor Q1.

The limiter is placed in series with the line so the current is from collector to emitter. Though shown polarized in Fig. 2, the limiter may be used with either polarity supply.

In order to design for a particular maximum current, select R_e such that

$$R_e = \frac{.6V}{I(\text{amps})}$$

and make R_b about ten times as large as R_e. CR1 and CR2 are silicon diodes such as 1N4002, 1N645, 1N2070, or just about any diode capable of at least 100 mA. Q1 is a silicon transistor capable of the current to which the limiter is designed.

It works like this. R_b is small enough to keep Q1 saturated as long as CR1 and CR2 are not conducting. As soon as the voltages drop on R_e reaches 0.6V, CR1 and CR2 conduct and regulate the output current by regulating the base voltage on Q1.

Gerald Beene ■

73 ARTICLE DIRECTORY 1970

This master article directory lists, by subject, all the major articles featured in 73 Magazine during 1970. Entries are first by subject (alphabetically), then by article title (chronologically). A brief abstract of each article appears once, though the article itself might be listed under more than one category. When no abstract appears and a subject heading is shown in parentheses between the author's call and the date of publication, refer to the parenthesized subject heading to read the abstract.

Antennas

AAB—AM—FM Modulation System

W2BSP Jan

Tongue-in-cheek technical article about a system the author actually uses. He calls it "frequency aperture" modulation. The most interesting part of the article is the author's clever adaptation of a 55 gallon drum for use as a 10 meter cavity.

Base-Tuned Center-Loaded Antenna

W2EEY Jan

An antenna *can* be center-loaded without having the reactive element physically present at the center of the antenna. Transmission line transfer of the reactive element is the key.

Variable-Impedance Mobile Mount

W1EMV Feb

A rotary switch with a few capacitors can effectively change the matching impedance of a mobile antenna.

Quick-Stop and Reverse Antenna Rotator Circuit

PY2AUC Feb

A simple rotor modification to make the antenna stop when you want it to. Also lets you suddenly reverse the antenna's travel without fearing damage to anything too high to reach comfortably.

The Glop Will Get You if You Don't Watch Out!

W2OLU Feb

The effects of glop (dirt and crud) on antenna connections. Contains suggestions for minimizing the likelihood of Glop build-up.

18-in. Dipole for 15 Meters

K9LGH Feb

Supersmall antenna for cliffdwellers; incorporates two printed-circuit radiating elements.

Lossy Transmission Lines

KH6IJ Feb

A description of the effects of an antenna transmission line's losses, and a discussion as to the insignificance of swr measurements under conditions of a lossy line.

How to Megger Your Antenna

W2EEY Apr

A simple, proved method for periodically checking performance of a transmission line and antenna system. Can uncover faults not indicated by swr measurements.

7/8-Wave Mobile Antenna for 2 meter FM

W2EUP Apr

An expert describes an antenna of original design, and compares it objectively with other antennas of commercial manufacture. In the Buffalo area, this 7/8-wave antenna has held the FM mobile gain record since 1967.

5/8 Wavelength Verticals

WA0NGV May

Theory and information on 5/8-wave verticals of various descriptions. Includes radiation-angle data, construction information, and necessary equations for original design.

The Little Wonder: Mark II

W5ZBC Jun

Another cliffdweller antenna. This one can be fashioned from an old pole lamp.

The 663 Beam

ZL2ASJ Jun

Six elements on 10 and 15, and 3 elements on 20m. Construction plans were left out, but were printed in the Aug issue (p. 83).

Quarter-Wave Top-Loaded Mobile Antenna

W5AZE Jun

An efficient, short quarter-wavelength dipole antenna for 20 meters.

Eleven-Element 2 meter Circular Quad

W4KAE Jun

A new type of antenna that seems to have a lot to offer.

The Sly Beam

ZL4TAH Jun

21 dB gain on 2 meters with a new approach to the construction of yagis.

Measuring the Difference Between Incident And Reflected Power

VE7BS Jun

The difference is the difference. Includes circuit for measuring reflected and forward rf.

The Effects of Temperature and Frequency On Coaxial Cable Loss

W9KXJ Jun

As transmission line temperature increases, so does loss — and vice versa. Complicating matters, the losses get worse as the operating frequency is raised. Includes charts.

Improving the Performance of Trap-Type Vertical Antennas

W2EEY Jun

The addition of another element can considerably improve the performance of multiband verticals. The added element can be automatically bandswitched and a transmission line system used which allows simple changeover from an omnidirectional to a directive radiation pattern.

A Practical DDRR Antenna

W6WYQ Jun

Ring-type low-profile radiator that is hard to build. Good for mobile rooftops.

Two Receivers from One Antenna

WA6UFW Jun

An easy-to-make signal splitter that allows maximum utilization and minimum loss.

Remote SWR Indicator

W2EEY Jun

Concentionally placed swr meters often do not indicate the true swr at the junction of the transmission line and antenna. Remote location of the reflected-power sensing portion of an swr unit is the key to true swr value indication.

The Low-Noise Antenna

WB6JNI Jun

Blasting the theory that an antenna always works as well receiving as it does transmitting.

Measuring RF Output

WA6CPP Jun

Using a cheapie meter to measure wattage.

Raising a Rhombic

W8DYF Aug

All you really need is space.

Log Periodic Antenna Designs for VHF/UHF

W3DUQ Aug

Three arrays are featured: 21—55 MHz, 50—150 MHz, and 150—450 MHz.

ATV: Getting a Better Picture

WA6BJV Aug

Plans for a good antenna and suggestions for other station improvements.

Brew 1 on 2 — a 2 Meter Coaxial Antenna

WA0RWQ Sep

The title is alluding to California's "Brew 102" beer. The article describes a beer-can coaxial antenna that can be fun to make if you obtain the cans as the author suggests.

Four-Wire Inverted Vee

WA6COB Oct

Simple but effective antenna for 40 and 80 meters.

Remote Quad Tuning

W6AJZ Nov

How to tune a quad stub from a control box situated at the operating console.

CW

The Combo

K4FQU Jan

A CW monitor that is installed between the key and the transmitter. Contains but one transistor. Simple. Effective.

Mobile CW

K6RA Jan

A fantastically great way to get yourself killed on a Los Angeles Freeway.

First Class Keyer Key

W6BLZ Jan

Quickie article describes a cute modification to modernize an inexpensive but readily available "bug."

A CW Monitor

WB2GQY Mar

How to get a 98¢ oscillator module to key on and off with rf. Uses a voltage doubler rf pickup.

Turning the AN/GRC-9 Into A Novice Rig

W6JTT Mar

A simple conversion puts this surplus unit on 80 and 40 meters. Converted, the rig will run about 15W. Includes a detailed power supply circuit. Modulatorless, the transmitter is intended for CW operation.

What Will Become of CW?

W5TOM May

A dissertation on the state of ham radio today, and suggestions for possible improvement. Makes a case — of sorts — for CW, and offers predictions for CW's role in amateur radio's future.

A Mobile CW Transmitter

W6BLZ May

For those who don't know what to do with their free hands while driving.

CW Can Be Fun

Staff Jun

An evaluation of Ord's DK-1 keyer.

QRP

WA3JBN Jun

Two simple rigs for CW operation on 40 meters.

How to Build a Keyer and Retain Your Status as an Appliance Operator

W9KXJ Jul

A couple of guitar picks and some relay contacts can turn out a pretty nice looking sending key.

Mobile CW Receiver

W6BLZ Jul

For people who just can't seem to get enough code during the evening at home.

The ICmitter

Goldstein Aug

Costs little and doesn't run much power, but it will put out a signal — AM or CW — on 40 through 160 meters.

Integrated Circuit CW ID Generator

W7PUG Sep

A device for automatic identification — with CW — of FM repeaters. Author also offers to supply PC boards plus computer printout of any call letters, as optimized with the author's computer.

Low-Cost Automatic Keyer: A First Project

WB4MYL Nov

Schematic, description, and circuit board layouts for an inexpensive keyer that can send from 10 wpm to over 30.

DX

How to Visit Foreign Countries

W2NSD/1 Feb

A few salient hints for prospective travelers and sometimes DX'ers.

Ham Exchange

WA2ELA Mar

First-hand report of a "ham exchange" whereby DX visitors stay with U.S. amateurs, then reciprocate later when the U.S. hams visit the DX country.

QSLing: Ham Radio's Own Con Game

VK4SS Jul

One ham's negative opinion of the state of DXing today.

Latham Island DXpedition

5H3LV Jul

Problems and successes in a recent DX trip to Zanzibar.

Worldwide ITU Prefix/Call Area List

W1SWX Jul

Reprinted from DX'er Magazine.

YO — An Interesting DX

YO2BO Oct

A look at Romania and a description of the hams and country.

FM

VHF—FM: A New Involvement

K6MVH Jan

The story of FM Magazine's demise and the promise of 73 to give adequate attention to FM, an area all but neglected by ham journals in the past.

Low-Cost Electronics: Japan's FM Invasion

K6MVH Jan

A brief overview of some of the 2m FM transceivers that are being inported for sale to the booming VHF ham market.

Setting Up the Tone-Burst System

W6TEE Feb

The little details that are necessary in setting up a toned repeater, including a tone-burst timer for the user mobiles.

Tone Decoder for Remote Switching Applications

K6MVH Feb

A simple and tested tone decoder that may be used for such repeater control applications as whistle-on and tone-burst access systems.

Encoders for Subaudible, Tone-Burst or Whistle-On Use

W6CZL Feb

An extremely simple and stable transistor oscillator circuit, with adaptations for the various modes of repeater control. Includes PC board layout and construction plans.

Frequency Synthesis: The Modern Way to Control Frequency

W2EUP Feb

A complete and comprehensive article covering theory and techniques of indirect frequency synthesis, plus schematics and a description of a practical 400-channel synthesizer used in a 2 meter FM transceiver, with only one frequency-determining crystal.

VHF—FM and You

K9STH Mar

A "what's-it-all-about" type article covering everything that's happening in FM right now.

6-to-12-volt Filament Conversion for the 41V

W6YAN Mar

Changing the cheaper 6V Motorola FM units to 12V types.

AC Power Supply Conversion for the Motorola 41V

K9PKQ Mar

Schematic diagram and helpful hints for converting Motorola's trunk-mounting mobile unit to a base station.

Remote Multifrequency Oscillator for Surplus FM Units

W2AUM Mar

Complete plans, PC layouts, and construction info for a four-frequency oscillator deck that can be used in the control head of such trunk-mounted units as GE, Motorola, Link.

Converting the Sonobuoy to a 2W FM Transmitter

W1BYX Mar

Schematic diagram, photo, and instructions for converting the AN/SSQ-23A underwater transmitter to a 2W 2 meter FM rig. Also tells where to get such transmitters.

Kris Scanning Receiver

Staff Mar

A close look at one of the newest entrants into the ham radio field.

A Look at Amateur FM Standards

WB6DJT Mar

A general survey of the VHF revolution with respect to repeaters over the past few years and some suggestions for planning ahead.

A Poor Man's Frequency Meter

W6YAN Mar

How to turn a cheap LM frequencu meter into an extremely accurate piece of test equipment. You'll need the front end from a Sensicon receiver, too.

The Fine Points of FM Operation

WB2AEB Apr

Good common sense for FM beginners. Includes good hints on setting deviation level.

Examining FM Repeater Operation

WB6DJT Apr

A state-of-the-art article telling it like it is, with suggestions as to how it ought to be.

A Repeater Controller

WA4YND Apr

The myriads of mechanical contrivances that repeaters inevitably wind up with can be replaced with transistor equivalents. . .with a resulting increase in system reliability and decreases in headaches for the repairman. Complete circuits, with timers, COR, keyer control, etc.

Understanding the Carrier-Operated Repeater

K6MVH Apr

The complicated repeater is not really so complex after all. . .it's only a matter of understanding the simple operations that are taking place when somebody transmits on the input frequency.

Evaluation: Standard 2m FM Transceiver

W6QGN Apr

A close look at the SR-C-806M transistor transceiver.

Directory of American Open Repeaters

Staff Apr

A comprehensive listing of open repeaters in the United States and Canada. Includes editorial introduction and writeup about repeaters in general.

FM Repeaters Under Fire From FCC

Staff Apr

The first published notice of FCC's infamous Docket 18803. Sketchy but essentially accurate.

A Word About Repeaters
WB2AEB — Apr
The trend for the future seems to be to use a compatible deviation of both narrowband and wideband rigs: this is accomplished with a peak deviation of about 8 kHz at the repeater transmitter. Other trends and characteristics also noted. Included with the repeater directory.

7/8-Wave Mobile Antenna for 2 meter FM
W2EUP — Apr
(Antennas)

FM—AM Transmitter-Receiver Aligner
W3JKL — May
A signal generator that can be used in conjunction with a transmitter to give a zero beat for frequency measurements. Also useful for aligning FM receivers.

The Intelligent Use of 2 Meters FM
K1ZJH — May
A general description of the way it's done on FM (it IS different), and a few words of wisdom to people who aren't used to working through repeaters.

A Low-Band Police Monitor
W6JTT — May
How to modify Motorola's old, no longer used 30D type receivers by building up a simple supply and diddling with the receiver oscillator.

The Wichita Autopatch
W@DKU — May
Tied in with the local repeater, this phone patch received approval from Ma Bell. Includes descriptions of the patch and tells how Ma Bell was conned into going along with the idea.

An FM Best Buy
WA7EMM — May
How to convert the world's rarest FM rig (Comco) from commercial service to the ham band.

FET Preamps for VHF FM
WA4WDK — May
Two good preamps are described — one for 6 and the other for 2 meters. Complete performance curves, construction data, schematics, etc. are given. Preamps are grounded-gate, which offers high gain, ease of tuning, and simplicity of construction.

Allied Portable FM Receiver
K9STH — Jul
An evaluation of Allied's A-2587 pocket FM receiver.

A Two-Channel Search-Lock for FM Receivers
W3DTN — Jul
Simple gadget turns a 2-channel rig into an automatic scanner type, and provides the added capability of locking onto a channel where activity is sensed.

Super Autopatch
K6MVH — Jul
Why automatic phone patches are important for public service. Includes construction data for a patch that does everything.

Repeater Audio: Time Out for Quality
K6MVH — Aug
Use of a cathode follower to pick audio directly from the repeater's discriminator can do wonders for an ailing amateur relay system.

Optimizing Antenna Separation in FM Repeaters
K6MVH — Sep
If the receiving range of your repeater can't match the output capability, the problem could be desensitization. And chances are you can solve the problem by as simple a step as moving the antennas around a little at the repeater site.

DyComm's 15W 2 Meter Mini-Amplifier
Staff — Sep
An evaluation of a ready-made 15W class C amplifier that can be used for VHF CW or FM applications, requiring only 20 mW of drive.

Integrated Circuit CW ID Generator
W7PUG — Sep
(CW)

Low-Cost Oscillator & Infinite Attenuator for Tuning VHF Receivers
K1CLL — Sep
A signal generator with a very reliable and repeatable attenuation device for adjusting receiver front ends to maximize sensitivity.

Controlling Repeaters with Tones
K6MVH — Oct
Basic repeater control logic, and how to set up a tone control system for tone-burst or whistle-on use.

Semiautomatic FM Channel Scanning
WA@QPM — Nov
Using ordinary flasher module, this unit connects to a two-channel FM transceiver to allow monitoring of both channels by a scanning sequence. Does not lock onto a signal.

2-Meter Minitransmitter for Repeater Use
WB6BIH — Dec
A straightforward, simple transmitter with five stages using five transistors.

Regency — an FM Late-Starter
Staff — Dec
A comprehensive comparison of the Regency 2 meter transceiver with other units currently available.

General Info

Fascinating Fundamentals: Volta and His Pile
W2FEZ — Jan
The interesting story of Volta and his experiments in galvanic research. Describes an early (and easily duplicated) battery.

Fascinating Fundamentals: The Terrible Jar at Leyden
W2FEZ — Feb
Interesting historical facts about the Leyden Jar; how to duplicate it and make your own capacitor.

How Do Ham Radio Stores Decide Trade-In Prices?
W2CEP — Apr
The owner of Stellar Industries gave this rundown on the way prices are figured in the amateur radio game. Stellar is no longer in the ham business, but the article is nonetheless applicable.

Beryllia — The Lethal Refractory
WB2PAP — Apr
Take another look at those tube boxes on your shelf; those ceramic jobs that are made with beryllia could be dynamite!!

Inexpensive New Semiconductors for the Ham
WA7KRE — Apr
Descriptions and representative circuits for a whole flock of recently introduced semiconductors from Motorola. Includes dual-gate MOSFETs, several power amplifiers, thyristors, rectifiers, etc. Circuits included: VHF amplifier, audio amplifiers, telephone amplifier.

London's Science Museum Demonstration Station
Ellison — May
A look inside the museum and a description of the amateur radio facilities there. Includes photos.

Plus Ten dB. . . .
W2OLU — May
A quick way to relate power to decibels, and an easy method for calculating one commodity or the other when one of the commodities is known.

Selectivity Has Come a Long Way
Swan — May
The theory of bandpass fillers and a description of Swan's newest entry. Includes performance specs.

Science Fairs: Science Education?
Mocking — May
A revealing look at the schools' approach to science education these days. Good reading for those who care.

Bigger Knobs for Better Performance
WB21CV — May
An encapsulated rundown on the findings of a high-cost program to human-engineer consoles. Modern science now says tiny knobs can cramp your style!

Epoxies for Electronics
W9KXJ — May
How to steal a trick from the professionals and use modern epoxies to perform the bonding that once had to be done with a hot soldering iron.

Comments on FCC Repeater Proposal
Staff — May
A point-by-point reprint of the FCC's Docket 18803, along with suggested revisions to make the rules more realistic and easier to live with.

Ground Support for the Powder Puff Derby
W7ZC — Jun
The ins and outs of providing communications for the most famous air contest in the world.

The Low-Noise Antenna
WB6JNI — Jun
(Antennas)

The Effects of Temperature and Frequency on Coaxial Cable Loss
W9KXJ — Jun
(Antennas)

Government Surplus Straight From the Horse's Mouth
WA9ANW — Jun
How to get on the Government's surplus gravy train. How to buy; how to bid.

Improving the Performance of Trap-Type Vertical Antennas
W2EEY — Jun
The addition o (Antennas) in consider-

The Club for Blind Amateurs
Champagne — Aug
Pictorial story of K1TPX, the Perkins Radio Club for the Blind.

Ham Radio Chess
W1EMV/@BMW W — Aug
Two schemes for annotating chess games for over-the-air play.

What Really Happened to Hamdom?
W9HBF — Sep
The author asks why we are in the state we are. He advocates QRO and a good beam as opposed to brute force power, and points to some uncomfortable comparisons between ham radio and citizens band.

YO — An Interesting DX
YO2BO — Oct
(DX)

AC Switching with Self-Powered ICs
W2FBW — Nov
A new approach to power switching of ac circuits: rfi is eliminated, power supply diodes are protected, switch contact wear is reduced, and tube heater life extended. ICs switch at the zero current point.

Pioneer Radio on the Prairie
W6CXC — Nov
Sentimental remembrances of E. E. Krebsbach and the contributions he gave to the field of amateur radio.

Helpful Hints

Proper Use of Silicon Diodes
1WA3ACL — Jan
How to use the ratings of diodes in your rectifier projects. Includes suggested applications for such diodes.

Simple Compact 6m Bandpass Filter
WA5SWD — Jan
A high-performance TVI for 6 meters that costs less than $5 to build. The filter is to be installed in the transmitter's transmission line.

Using Diodes for Adapting AC Relays to DC
WA5SWD — Jan
Simple shorty article showing the right way to use diodes for low-voltage rectification where the object is to use dc relays with an ac supply.

The DX-35 Revisited
W2AOO — Feb
A trick or two for updating Heathkit's popular DX-35 Novice rig.

From Breadboard to Printed Circuits the Easy Way
K1AOB — Feb
A simple system for making PCs by using an Xacto knife to cur around original artwork.

ProfessionalP PCs From Roll-Your-Own Negatives
K6MVH — Mar
A means for creating high-quality printed circuits without the time-consuming and expensive darkroom processes.

Easy Diode Testing
K4JK — Mar
A clever means for nondestructively testing "bargain" diodes to learn their PIV.

Super Sizer
WA3AQS — Mar
Many little modifications that will cut the resale value of Heath's Sixer, but which will surely make the rig work better.

Renovating Surplus Meters
WA@ABI — Apr
A test or two, a dab of white paint, . . . and presto!

Keep 'Em Cool in KPO Cans
G3KPO — May
Construction data for building simple heatsinks for vacuum tubes. The idea is to extend tube life and reduce heat dissipation within the tube envelope.

Epoxies for Electronics
W9KXJ — May
(General Information)

Bigger Knobs for Better Performance
WB21CV — May
(General Information)

Educated Idiot Lights

Holford — May
How to modify the car's "idiot light" warning system by adapting a buzzer to complement it.

Coax Adapter — VHF to BNC

W9MEV — Jun
A "quickie" article shows how to combine fittings to get a professional looking adapter.

Useful Cable Clamps

WA6CPP — Jun
A brisk shorty telling how to use hose clamps to hold cables.

De-RF Your VTVM

WAØFFJ — Jun
A quick and easy way to clean it up.

Two Receivers from One Antenna

WA6UFW — Jun
(Antennas)

Measuring RF Output

WA6CPP — Jun
(Antennas)

Installing the Swan 250C Noise Silencer

WA6CPP — Jun
Pictorial story tells how to do it neatly.

A Soldering Gun Tip

WB6PKA — Jul
Using silver-plated wire for soldering.

Mount That Mobile Right

K4IPV — Aug
The right kind of mobile installation will result in bigger signals, better operator safety, and more fun in hamming on the road.

ATV: Getting a Better Picture

WA6BJV — Aug
(Antennas)

Converting 24V DC Relays to 115V AC

Douglas — Sep
Three circuits and a brief article on how to accomplish this task.

Reed Relays for UHF/VHF Coaxial Switching

W7CRY — Sep
How to use reed relays in place of the expensive coax relays and get better overall performance. Includes frequency loss and isolation curves.

Neater Cabling With Nylon Cord

WAØABI — Oct
Use of nylon and heat to make it neat.

Improving Regulation in High Voltage Supplies

K6BW — Oct
Shorting out the surge resistors with a delay circuit to improve performance of a high-voltage regulated power supply.

Calibrate that Calibrator

W2KPE — Nov
Using WWV to calibrate the receiver 100 kHz calibrator more accurately than it has ever been calibrated before.

Solid-State Delta-F Control for SSB Exciters

W4NVK — Dec
Vernier tuning eliminates dial backlash and other tuning anomalies, and gives precision variable-frequency control of operating slot.

Two-Terminal Current Limiter

Beene — Dec
Simple series circuit holds current to safe level.

Humor

The Manuscript Game

Staff — Jan
Every good article gets its due reward.

How I Read the Radio Operator's Handbook and Found Happiness . . .

Johnson — Mar
The author's story of how he mastered ham radio theory overnight.

Bob-Bob-Bobbin' Along

K1YSD — Mar
Utter chaos and hilarious confusion from the pen of 73's only insane author.

That Contest Craze

VK4SS — Aug
An old tiger bares his fangs.

Code Practice a la Baby Talk

W9OXA — Sep
Sometimes there are advantages to becoming a ham that aren't even listed in the manuals.

Camouflage

K99AZG — Oct
How to buy lots of ham gear without letting the old lady know.

Clinks in a Vacuum

Derfler — Dec
A low-pressure article for wives. (Or for hubsands to show wives who don't dig radio.)

Hams are a Funny Bunch of People

K3KMO — Dec
A few of the paradoxes that make it easy for us to laugh at ourselves.

Yipes, It Talks!

W2FEZ — Dec
Fool your friends with a newspaper that talks. It's a homebrew electrostatic speaker fashioned from papers and foil.

IC Projects

Frequency Synthesis: The Modern Way to Control Frequency

W2EUP — Feb
(FM)

New Linear ICs for the Ham

WA4KRE — Feb
A down-to-earth description of Motorola's latest ICs doe amateurs, along with schematics lifted from Motorola's application notes. Includes power supply and regulator circuits, amplifiers, modulators.

A Logical Approach to Surplus Buying

K5JKX — Mar
How to identify and test ICs commonly found in the surplus market. Includes an extremely literate discussion of the principles of logic.

Low Frequency I-F Modules Using ICs

K1CLL — Mar/Apr
Description of what the author feels is the ideal i-f. This text includes a very good dissertation of the ins and outs of such popular i-fs as 455 kHz.

High-Performance Power Supply Using an IC Voltage Regulator

KØECF — Jul
0-20V at up to 500 mA in a tiny package.

An Impedance Multiplier for the VOM

K6DQB — Jan
Using an IC to do the trick.

The ICmitter

Goldstein — Aug
(CW

Three Versatile IV Testers

WA2IKL — Sep
This article lists pin diagrams for the common ICs and describes simple testers for checking digital, linear, and counter ICs.

Understanding and Using Integrated Circuits

W6DNS — Oct
All the basics; what they are, how they're used; why they're used.

The Phase-Locked Loop Comes of Age

K5JKX — Oct
A new IC and how it can be used in some pretty sophisticated circuitry.

Low-Cost Function Generator for Experimenters

WA2IKL — Oct
Makes sine, square, and sawtooth with excellent quality.

IC Marker Generator

K4BBC — Oct
Simple IC device gives marker signal when you approach the edge of your authorized band.

Practical IC Regulator Circuits for Hams

WB2EGZ — Oct
For a 500 mA supply.

ICs for Amateur Use

K1CLL — Oct
Describes a couple of good rf amplifiers using inexpensive ICs. One for 6 meters, another for 40.

AC Switching with Self-Powered ICs

W2FBW — Nov
(Gen. Info.)

Low-Cost Automatic Keyer: A First Project

WB4MYL — Nov
(CW)

Solid-State Transceiver for 40 Meters: the SST-I

W9ZTK — Nov
A modularized QRP rig with built-in swr bridge, CW monitor. Has ICs in audio and receiver sections.

Solid-Sate Exciter

W6YUY — Dec
ICs and transistors makes this SSB exciter modern, inexpensive, and efficient.

(HR PROJ)

Yipes, It Talks!

W2FEZ — Dec
(Humor)

Keyers

Transceiver Companion

W6AJZ — Jan
This is a complete control console and accessory for the transceiver that doesn't already have everything. It includes compressor, preamp, electronic keyer, phone patch, speaker, clock, and the kitchen sink all in one neat package.

CW Can Be Fun

Staff — Jun
(CW)

Low-Cost Automatic Keyer: A First Project

WB4MYL — Nov
(CW)

Mobile

Mobile CW

K6RA — Jan
(CW)

Base-Tuned Center-Loaded Antenna

W2EEY — Jan
(Antennas)

SSB-AM-FM Modulation System

W2BSP — Jan
Tongue-in-cheek technical article about a system the author actually uses. He calls it "frequency aperture" modulation. The most interesting part of the article is the author's clever adaptation of a 55 gallon drum for use as a 10 meter cavity.

The Camper — Mobile and Portable

WA9EHE — Feb
How to get the most out of a ham station when *you own a camper*, plenty of radios, and like to travel a lot.

Variable-Impedance Mobile Mount

W1EMV — Feb
(Antennas)

7/8-Wave Mobile Antenna for 2 meter FM

W2EUP — Apr
(Antennas)

RF Riviera Style

K9BDJ — May
The story of a Buick-owner's problems and how he traced them down in order to eliminate mobile interference.

A Mobile CW Transmitter

W6BLZ — May
f t
(CW)

An FM "Best Buy"

WA7EMM — May
(FM)

A Ham-Style Burglar Alarm for the Car

K2JLD — May
Description of a scheme for foiling prospective rig thieves.

Educated Idiot Lights

Hplford — May
(Helpful Hints)

5/8 Wavelength Verticals

EAØNGV — May
(Antennas)

The 27-Minute Mobile Limiter

W7SOH — May
How to build an effective noise limiter. As an alternative, the author shows how to modify an existing Bishop type noise limiter. The modification takes 27 minutes.

A Practical DDRR Antenna

W6WYQ — Jun
(Antennas)

Quarter-Wave Top-Loaded Mobile Antenna

W5AZE — Jun
(Antennas)

Installing the Swan 250C Noise Silencer

WA6CPP — Jun
(Helpful Hints)

Mount That Mobile Right

K4IPV — Aug
(Helpful Hints)

6V From 12 — The Easy Way

K3GSY — Sep
High current regulator that uses two transistor and a zener. Better approach than the "dropping resistor" idea.

Semiautomatic FM Channel Scanning

WAØQPM — Nov
(FM)

Noise Clippers

A Noise Blanker That Works

W8RHR — Apr
It DOES work, but the article somehow got into print without being edited, and there are some errors. Those who want to build should drop a card to editor of 73 to get straightened out on discrepancies.

The 27-minute Mobile Limiter

W7SOH — May
(Mobile)

Installing the Swan 250C Noise Silencer

WA6CPP — Jun
(Helpful Hints)

Novel Ham Radio Projects

Converting the 4CX1000 into a Lamp

K3QKO — Jan
A clever lamp for the ham's ham. Even has a switch fashioned from a coaxial connector. Better not to use a new tube for the lamp, though; it will have somewhat of an impact on the total cost of the project.

Transceiver Companion

W6AJZ — Jan
(Keyers)

The Dip Light

VE3ECU — Mar
A grid-dipper that uses lamp intensity instead of a meter.

Add Spotting to your VFO

K8BYO — Mar
Cute and simple technique that lets you hear the vfo without transmitting.

Reverse-Current Charging

K8YUC — Mar
With an almost foolishly simple technique you can successfully recharge ordinary dry cells, and make them hold the charge again and again.

Single-Sideband on the All-Wave Radio

W7CSD — Apr
A miniature tunable oscillator provides an ideal source for a beat-frequency signal, and allows you to hear code and SSB on any selective receiver without making modifications to your store-bought gear.

A Low-Band Police Monitor

W6JTT — May
(FM)

A Ham-Style Burglar Alarm for the Car
K2JLD — May
(Mobile)

Educated Idiot Lights
Holford / How — May
(Helpful Hints)

The *Consummate* Console
WB2FBF — Aug
Increasing station efficiency and enjoyment with a broadcast-style console. Include's plans and construction data.

IC Marker Generator
K4BBC — Oct
(IC Projects)

Solid-State 10-Minute Timer
WB4MYL — Oct
Plans, layout, and PC pattern for a MOSFET timer for various station functions or repeater applications.

Power Supplies

Simple Bench Power Supply
ZL2AMJ — Jan
Provides four output voltages, three current-overload limits. The techniques described can be applied to other power supplies.

Proper Use of Silicon Diodes
WA3ACL — Jan
How to use the ratings of diodes in your rectifier projects. Includes suggested applications for such diodes.

A 10m/CB Preamp
WA3HMW — Jan
Using a surplus 10m preamp with a slight amount of conversion. Details include power supply instructions.

Using Diodes for Adapting AC Relays to DC
WA5SWD — Jan
Simple shorty article showing the right way to use diodes for low-voltage rectification where the object is to use dc relays with an ac supply.

New Linear ICs for the Ham
WA4KRE — Feb
(IC Projects)

Turning the AN/GRC-9 Into a Novice Rig
W6JTT — Mar
(CW)

A Simple Bias Regulator for Linear Amplifiers
ZL2ANG — Apr
Shunt regulation for bias supplies offers the advantage of low constant current drain, and it can be used with the neglected — till now — class B and AB2 linears.

Vacuum-Tube Load Box
Ashe — Apr
Schematics, photos, and construction details for a power supply test set . . .

Power Supplies From Surplus Components
WB6BIH — May
Lots of theory and a few schematics for converting old surplus junk into something useful. If you're a mathematician, this is certainly your bag.

High-Performance Power Supply Using an IC Voltage Regulator
KOECF — Jul
(IC Projects)

More Notes on Diode Stacks
W2BDG — Sep
A description of GE's high-power (5 kV at 300 mA) rectifier modules.

6V From 12 — The Easy Way
K3GSY — Sep
(Mobile)

Simple Regulated *Power Source for* ICs
W1RAN — Oct
Regulated power supply using series diodes (not zeners) to give precise values of required voltages.

Practical IC Regulator Circuits for Hams
WB2EGZ — Oct
(IC Projects)

Improving Regulation in High Voltage Supplies
K6BW — Oct
(Helpful Hints)

Differential J-FET Preamplifier
W4KAE — Nov
Design, construction data, and performance curves for a low-noise preamp using an RCA CA-3028 J-FET. Includes separate power supply circuit.

Your Second Linear
W4AYI — Dec
High-power linear amplifier using a 3-500Z vacuum tube for the final. Includes schematic for a kilowatt power aupply.

QRP

"Quazar" QRP 40m DSB Transmitter
WA5WWN — Jan
Good low-power rig for sideband or CW; uses 4 transistors and an audio amplifier module.

Postage Stamp Transmitter for Six
K1CLL — May
Complete plans — including part list, layout, schematic, and construction details for a transmitter that is an eighth of an inch thick and only 3/4 in. square. This one really works, too.

QRP
WA3JBN — Jun
Two sample rigs for CW operation on 40 meters.

The ICmitter
Goldstein — Aug
(CW)

VHF AM Transmitter Using Low-Cost Transistors.
Brubaker — Aug
If it'll work on AM it'll work on FM.

ICs for Amateur Use
K1CLL — Oct
(IC Projects)

2W 6 Meter Transmitter Using the Heterodyne VFO
K1CLL — Nov
Breadboard design, tuneup, and performance of an rf power stage on 6m using a $3 transistor and a stable vfo circuit.

Solid-State Transceiver for 40 Meters: the SST-1
W9ZTK — Nov
(IC Projects)

2-Meter Mmitransmitter for Repeater Use
WB6BIH — Dec
(FM)

Receivers

Solid-State Double-Bandwidth Tunable I-F Converters
K1CLL — Jan
A good tunable converter can get you any frequency or band in the VHF range you want. This article tells how, and it includes schematics, parts lists, and complete instructions.

A 10m/CB Preamp
WA3HMW — Jan
Using a surplus 10m preamp with a slight amount of conversion. Details include power supply instructions.

A Simple IC Q-Multiplier
W2EEY — Feb
Using an IC opamp for a Q-multiplier. Advantages include simplicity, broad range of operation, and variable Q and peaking frequency.

High-Performance Converter for 6
WA9HES — Feb
Tube-type converter uses a Nuvistor. This article may become valuable as the last tube converter circuit ever published.

Low Frequency I-F Modules Using ICs
K1CLL — Mar/Apr
(IC Projects)

High Performance I-F Amplifier and AGC System
ZL2BDB — Apr
For CW or SSB work, you'll find this system hard to beat with its fast-attack, slow-decay characteristics. A wide latitude of stage gain is assured with both forward-and reverse-acting age elements.

Hot Carrier Diode Mixer Converter for 2 Meters
WA6NCT — Apr
Low noise, high gain, excellent overload resistance, and a very high degree of isolation combine to make the hot carrier diode particularly attractive for applications in receivers and converters. This article has good PC layouts, photos, schematics.

FET Preamps for VHF
WA4WDK — May
(FM)

I-F Filter, Converter, AVC "Ideal" Circuits
K1CLL — May
The second half of Hoisington's two-article series on the ideal i-f. This one includes breadboarding the complete I-f system.

450 MHz Mighty Mite
K9VXL — Jul
A superregenerative receiver for 432 MHz. Includes PC layout.

Mobile CW Receiver
W6BLZ — Jul
(CW)

Deluxe Receiver Gain Control
VU2JN — Sep
Improving age performance in tube-type receivers with the addition of a transistor control circuit. Includes chart showing tracking curve.

A Versatile and Stable MOSFET Converter for 144 MHz
WB6YVT — Sep
A low-noise, high performance converter with excellent gain.

The Phase-Locked Loop Comes of Age
K5JKZ — Oct
(IC Projects)

Differential J-FET Preamplifier
W4KAE — Nov
(Power Supplies)

RF Applications of the Dual-Gate MOSFET
Sir — Nov
Application suggestions from the engineering desk at Fairchild Semiconductors. Includes receiver circuits and amplifiers for VHF.

Repeaters

Setting Up the Tone-Burst System
W6TEE — Feb
(FM)

Tone Decoder for Remote Switching Applications
K6MVH — Feb

IC Troubleshooting: A Matter of Temperature?

Many hours can be wasted troubleshooting IC equipment if you overlook one important characteristic. The popular Fairchild epoxy case ICs and the Motorola MC 700 series and HEP (dual in-line package) series are designed to operate between the temperature extremes of +59° F to +131° F (Fairchild) or +167° F (Motorola).

If your shack is in the garage like mine or at least unheated, you may very well be operating these ICs below their design temperature range during the winter months. Therefore, if your keyer, counter, or whatever seems to be operating erratically or not at all, take it into the house and give it six or more hours to attain room temperature. Then see if your trouble is still there. You may save yourself alot of time and frustration. (You may also have to buy a heater for your shack.)

Bottomless

I would like to take advantage of your most gracious money saving special 3-year subscription to 73. I still have a card you gave me at a Hamfest last year so I could get 3 years for $10, but I suppose it's too late to use it now. 73 is still the best ham magazine on the market, and I am tired of having to run down to the dirty book store on Broadway in San Francisco's "Topless-Bottomless" North Beach night club strip. You would be surprised, though, how many hams from all over I have met standing in that dirty book store reading 73.

So please accept my check for a 3-year subscription to 73, and come on out to California again when you can, and maybe you can stop in and meet some hams. They're always in the dirty book store reading 73.

Larry Johnson K7VZH

Jordan

After attending the ARRL convention, and sitting in on several of your meetings, I felt that I should write you. First of all, may I honestly say that I found the most interesting part of the entire convention to be located in the 73 room on the 4th floor. In particular, I was fascinated with the slides of King Hussein and Jordan, and the slides of YO2BO, whom I talked with at YO2KAC in the late 1950x. As one of those who spoke with you when you operated JY1 in Jordan, I sent my QSL card to Box 1055 in Amman and received a beautiful QSL card personally signed by the king.

I then decided to write again and request an autographed photograph of His Majesty suitable for framing. In the letter I told the king that I was a Social Studies teacher and that I would surely appreciate an autographed photograph that I could not only use for educative purposes, but also could frame for display purposes in my radio room. I really never expected an answer from such a busy and important person. About a

New! MULTI-ANTENNA COUPLER

Eliminates Antenna Switching

- Change bands without having to switch antennas!
- Combine your antennas into a multi-band antenna system while retaining optimum antenna performance on each band!
- Coupler feeds any combination of antennas from a single transmission line! Saves operating time! Saves coax and switches!
- Coupler isolates the line from all antennas but the one in use!
- Works with all types of antennas! Handles full legal power!
- Models available for any bands, 2 to 160 meters! Weatherproof!

Shown above: Model 3, for 10/15/20 meters. Terminals: SO-239 $29.95 ppd.

antennalabs

POST OFFICE BOX 458, OCEAN BLUFF, MASSACHUSETTS 02065

month later, however, the postman brought a large white envelope with ten stamps on it. On the back of the white envelope was a large gold crown.

Upon opening the letter I was amazed to find another QSL card signed by the king along with a personally autographed photograph dated July

25, 1970. Both the date and the signature were obviously in the king's own handwriting. I have framed the card, picture, and stamp section of the envelope and am enclosing a picture of it with this letter.

Vernon G. Dameron, Jr. K1DRN

You have no doubt kept up with the situation in Jordan in the last few weeks. According to the reports I have heard the situation is bad, especially in regards to medical help, food supplies, and so forth. Perhaps someone else has already made this suggestion but I was thinking it might be helpful if we hams banded together and all pooled our contributions for some help to the people in Jordan. I don't know who, if anyone, could organize such a program within the ham population but I would help if such a program is feasible.

The king was very friendly while you were there and it would be very generous on the part of the hams of the U. S. if we could help him in his time of need. I would appreciate your comments on this. Keep up the good work in 73. I am now a lifetime subscriber and am happy to be one.

Camouflage

I just finished reading K9AZG's article CAMOUFLAGE, 73, October 1970, and I think I can help him out. He was in a similar position to mine, trying to get a 50 ft mast and tribander up without letting the XYL know. I solved the problem by covering the top section of the mast with brown paper, adding a few branches or so on it, and "planted" it. Every few months or so I added a section to the bottom to make it "grow." The tribander was painted green and covered with leaves. Next I "pruned" the lower branches off, leaving only the beam. The brown paper eventually falls of, and if the XYL is at all near-sighted, the system is almost foolproof.

WAAS

Do you still issue the WAAS certificate? If so, will you please forward the necessary forms so that I may make application in the name of the club who sponsored and operated K6SB for the San Diego 200th bicentennial celebration. K6SD operated from October 1968 until October 1969 contacting as many hams as possible while celebrating San Diego's 200th birthday. During that year we were able to contact every state in the union, including Alaska and Hawaii, except Delaware.

So you can see K6SD does truly qualify for "Worked Almost All States."

Robert R. Smith WB6ODR
President El Cajon ARC

Yup, still available. Send 49 cards and $1.00 to cover costs of mailing, etc. . . . Wayne

FM Coverage

I am involved with two repeater groups here in the Denver area, and am in charge of a project to set up a new repeater for the Colorado Civil Air Patrol west of Denver, Colo. Thank you for the excellent coverage your magazine has given during 1970 to FM repeater activities and techniques.

Inflation in a Nutshell

Popular opinion seems to be that the FCC fee hike is an inflationary move. Well let's get things straightened out. The fee hike happens to be a noninflationary move. By making amateurs pay more for their licenses this will take money out of circulation giving hams less to spend.

The whole thing that starts inflation rolling in the first place is the fact that people have too much money to spend. This action of spending puts more money into the hands of the business man. When he gets more money, his workers want more money. When the workers get more money this cuts down on the profit margin of the business man. Seeing that he is making less money the business man will raise prices to equal what he was making before. And the cycle goes on and on.

Joseph F. Lutz WB8EAS
2951 S. Moreland Blvd
Cleveland OH 44120

Delightful theory, but I don't believe it. I tend to agree with the economists who feel that historically inflation arrives on the heels of the night shift at the Treasury Department when they print more money than is being taken out of the economy in taxes.

. . . Wayne

CBers and Hams

What's going to happen to American Private Citizens' Radio? That's how I refer to all civilian radio communications, chiefly amateur radio and CB. Today we are in the strange and destructive position of having two separate and competing civilian radio services. Competing for members, prestige, and frequencies. How absurd! Under this set-up it's not only likely, but inevitable that conflicts will arise, and it's not too difficult to see who's been winning the last few years. I don't know how this unfortunate situation developed, completely.

I think Wayne Green came close to the solution a couple of months ago with the proposal of the Hobby Class license. This would move the CBers and their short range communications to 220 MHz, the least wanted ham band. Actually it was sort of a compromise, but the important point is: it would unite the two services into a single licensing and communication structure! I support this 100 per cent. But. There are problems. 875,000 CBers won't relish the thought of replacing their equipment, just so they can call themselves hams. Most people already think they are!!

Anyway, how about a conciliatory approach to CB? They're not dumb. Most are friendly and some are real sharp ops. If we can assimilate and unite the two radio services, not abruptly but as fast as possible, then we will be able to provide better total service, and we will have a much more powerful position in the national and international radio structure. It won't be easy, certainly; but it appears to be the only reasonable solution that would not interfere with the distinct but related services we provide.

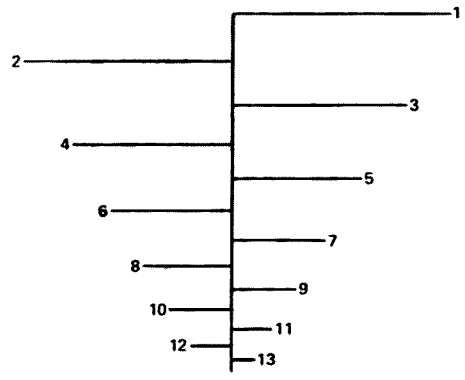
Marshfield WI 54449

Boo Boo



I have been receiving a tremendous amount of mail concerning two items in the August 1970 73 article on Log Periodics. Perhaps you could print a couple of items to straighten things out for your readers,

In middle columns of Table 1 (p.45), the third longest element length is 1.404 ft., not 1.304.

Also, perhaps you could redraw Fig. 1 with a top view of one boom assembly only. My questioners aren't sure of the element attachments which are not clear in the figure.

Try this idea:

TOP VIEW (one boom)

I hope you can find room to put this in 73 real soon to straighten people out.

Bill Nagle W3DUQ
RD 1 Box 188A
Honey Brook Pa 19344

Busted

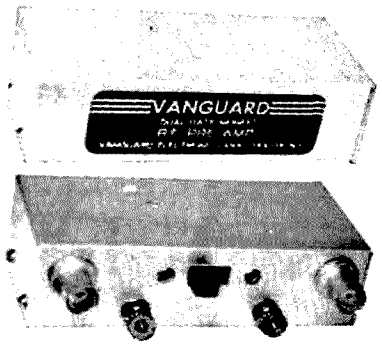
My fictional story, "That Contest Craze," in August '70 issue of 73 (in which I am not too kind to a young cop who slaps on me a $5 parking fine) has prompted members of the police force here and abroad to write and say, "Why send us up...Don't we have enough trouble with the teenagers without an oldie like you getting on the wagon?"

Constable First Class Gerry Letford (VE3FTV) has added another $5 violation fine (No.110932) for illegally parking my Big Red Kangaroo car in his hometown of St. Catherine, Ontario – and if unpaid a warrant follows.

Another Constable ham mate in the north of my home State has invited me up for a few days. He guarantees to land me with something heavier than a parking fine.

In the local village here, the sergeant (who borrows my 73 mags) booked my son and said, "I'd prefer to give this ticket to your OM."

A HAMSHACK WITHOUT A GLOBE?
Ridiculous!



Particularly when these fabulous Hammond globes (the best in the biz) are available at our **LOW PRICE.**

13" inflatable globe (guaranteed, by the way), regularly selling for $15, now special, while they last, **ONLY $10.**

13" lighted globes, regularly $25, now **ONLY $15.** We have a few of these in stock and when they are gone, that is it.

RADIO BOOKSHOP
Peterborough, New Hampshire 03458

DUAL GATE MOSFET
PRE-AMPS

to 175 MHz. **$21.95** ppd.
to 300 MHz. **$25.95** ppd.

NEW FOR 1970!
The above models now have rf gain control.

For 300 to 470 MHz
See Model 202 in our catalog.

- Available from 5 MHz. to 450 MHz. Bandwidth is approximately 3% of frequency.
- Voltage gain 30 to 40 DB depending on frequency.
- Two Dual Gate MOSFET amplifier stages with each having a tuned input and tuned output. Each Dual Gate MOSFET is actually an integrated cascode circuit thus giving you 2 cascode circuits equivalent to 4 triodes.
- Exceptionally low noise (2.5 DB at 175MHz.), greatly reduced cross modulation and 10 times the dynamic range (signal handling capability) of the best bi-polar transistors. Also superior to preamps using junction FETs and Single Gate MOSFETs.
- Internal connections for high impedance AGC or manual gain control if needed.
- Type BNC input and output receptacles for minimum loss at UHF. Standard impedance is 50-75 ohms.
- Carefully tuned at our laboratory with sweep generator and oscilloscope for the best bandpass characteristic.
- Full wave UHF diodes protect input transistor.
- Operates on 6 to 16 volts DC, 5 to 15 Ma.

New York City and State residents add local sales tax.

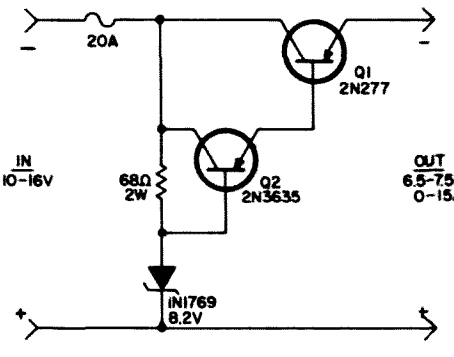
Blunders, Blunders



I still think your magazine is the greatest for the ham; have continued to think so ever since I subscribed very early in your magazine's career. Keep it up.

I want to be an old stinker and point out a couple of technical goofs in Sept 73. First, a little layout problem on page 30. Figures 1 and 2 are obviously interchanged. Otherwise, I have to suspect that it will work fine. I'll soon know; I am in the process of converting my old Heathkit grid dipper, since most of the key parts can be used.

Now, look at page 26 (same issue). That voltage dropper has something goofed up on it. The way it is drawn, Q1 will never conduct. Either Q1 and Q2 must be changed to corresponding NPN types or the input and output polarities must be switched (with a corresponding reversal of the zener diode). Otherwise, it seems to be a good scheme, within the limitations already mentioned by the author.

Harry K. Long, W7CQK
220 Seneca Ave NW
Renton, Washington 98055

You're right in both cases. Here's the correction for the p. 26 goof.

. . . Ken

Objectivity

This letter has a dual purpose. As long as I must write to you, I want to express my deep satisfaction with the policies of the mag. 73 mag has reached a height of editorial freedom I have not encountered even in Time or Newsweek. 73 allows each of its editorialists complete freedom while it has also opened its pages to critical comment and occasional discussion. Your heading to the "Letters" shows that you are interested in the irate and sometimes ignorant views as well as informed, intelligent ones.

Jim Altman WA0UWL/2
Box 6136, River Campus Sta.
Rochester NY

Politics, Religion and Sex

I have been an amateur for 8 years now and have become somewhat sick with the regular routine in which a QSO is supposed to be carried on. A few months ago I began to experiment on 40 meters in the way of trying to make a QSO more meaningful. I have been told by many people on the bands that politics, religion, and sex shouldn't be discussed in a QSO, but my personal feelings on this subject is different from that of the majority of hams. We are a society and almost a big fraternity of people with different interests and thoughts and if we want to get to know each other better, we should learn by our QSOs how each of us thinks. In the process of my experiment I found many amateurs that went along with my ideas. We discussed topics ranging from Vietnam to women's liberation. But it seems that whenever we would get into a sticky subject one of the members of our society would come on to the frequency and throw a carrier on, whistle Dixie, or sing the Star Spangled Banner, as the case may be. As other groups on the amateur bands have found, whenever someone disagreed with what you are doing – no matter if it is in the form of breaking the norms of the frequencies or conducting a net such as the one conducted by the students – choice stations show their intelligence by throwing all sorts of interference on the frequency. These kinds of people don't deserve the privilege of operating amateur radio.

I'd like to relate a story to the readers of 73. I have a very good friend on 40 meters (K2PJG). Bob is crippled from the waist down and is confined to a wheelchair. He is very active on ECARS and does an excellent job as monitor control. He has frequently been the recipient of all kinds of insulting remarks and has almost given up hope on the bands. I happened to be on the frequency one day when one of our fellow hams came on and started to insult Bob. When I broke in, the fellow insulted me as well. After the QSO I ran into Bob and he asked me if I knew of anyone who wanted to buy his rig. I have also thought about selling my 40 meter equipment.

Going back to my original topic of sex, religion and politics, I feel that the amateur bands might be more exciting and challenging to hams if some other hams would try my method of learning and discussing the problems of the world today. And maybe if more of us discussed problems and issues of the world and the amateur bands, there might be less conflicts and dissatisfied hams today.

Incentive Licensing — Pro and Con

The following letters are representative samples of letters received in response to 73's incentive licensing questionnaire. Those opposed to IL far outnumbered those for; thus, we cannot reprint all of the letters against the principle, even though the "for" letters reprinted here are the sum total of all letters backing incentive licensing we received from amateurs as of 1 October.

Pro

Anything as worthwhile as amateur radio is worth the time and effort involved in learning the code (20 wpm). My gripe is that you may interpret my responses to your biased advantage, so I have only answered the questions you will have difficulty biasing.

Jerry Pope W4YRY
5112 Cedarwood Dr.
Raleigh NC 27609

I am for incentive licensing, but I think the principle should be reconsidered, perhaps favoring new bands as an incentive.

Jack Petree WB4OVX
Box 5175
Roanoke VA 24012

The only answer I can give to anyone opposing an incentive of any kind is that he must be classed as too lazy to want to better himself and (improve) his knowledge.

Bill Cooke W3GBB
427 Crain Hwy NE
Glen Burnie MD

I favor IL, but all amateurs who held the original Class A license should be issued the Extra automatically. They earned the top benefits, so why take them away?

Paul Fritich W3HHC
11 Oakleigh Rd.
Allentown PA 18104

I have Extra class...took many days of code practice but consider the time well spent. Some people will never pass the Extra, but most have the capability to do so if they really want to.

Bob WB9ABT
Rt 1 Box 269
Lake Zurich IL 60047

Twenty wpm is the speed of the expert and Extra class should be expert. Incentive licensing gives one something to strive for, keeps the mind strong. Without (such an incentive program) some people would tend to grow stale. I think incentive licensing should be as the name implies – an incentive, something extra – not something restored that was previously taken away.

John Mrozinski WB2EXI
155 Eckford Street
Brooklyn NY 11222

Con

"Indian giving" – that is, offering something in exchange for a demonstrated proficiency in certain skills then revoking that something – is a very poor way of creating goodwill.

M. W. Macy W9UM
Rt 4
Syracuse NY 46567

I want to see ham radio grow – why not give it a chance? The Generals should be given back all the bands taken from them. If incentive is necessary, let the Extra have a small part of one band for phone and code. It is not hard to see why so many people say to hell with the FCC and the ARRL and go to CB where they can have almost as much enjoyment and can work the country without all this nonsense!

Roy Gunter K9GNK
1637 Rock Spring Dr.
Alton IL 62002

In spite of the fact that I am against IL, don't get the idea that I do not study and strive to improve my knowledge of amateur radio. It's just that I would rather see us go back to the previous system.

Richard Weiner WA8WMC
Rt 2 2560 Lincoln Rd
Ludington MI 49431

Hams in Alaska are under a particular hardship with respect to upgrading because of the tremendous distances involved in getting to Anchorage (where exams are administered). But I am against IL regardless of where I am located. Thanks for standing up for the majority of amateurs, who are against incentive licensing.

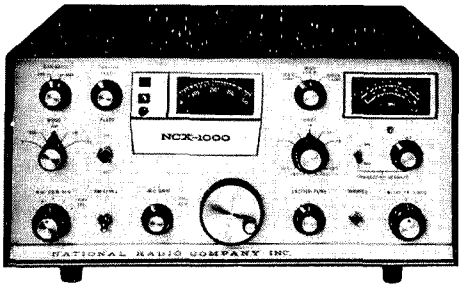
Jack Bone KL7GKY
Sitka, Alaska

I'm certainly glad the FCC doesn't have anything to do with my birth certificate, marriage license, bachelor's degree, etc., where revocation of privileges could really be serious!

C. H. Smith K0ERL
611 Wesley Dr.
Farmington MO 63640

Granting extra privileges to a few at the expense of the majority is hardly justifiable. The ARRL never proved it was speaking for a majority – surely the FCC must know that!

Theron Lillie WA2UIG
190 Henrietta St.
Rochester NY 14620



I don't favor IL the way the ARRL presented it and as far as I am concerned they can go to h— with their incentive licensing.

John Perlick WB0ADO
3400 Edgewood Ave North
Minneapolis MN 55427

Thanks for giving us hams the opportunity to express our feelings about IL. I do not favor the principle. I can see no useful purpose in knowing how to send and receive CW at 20 wpm unless someone simply wants to be a faster operator. The entire mess has dealt a severe blow to amateur radio; I sincerely hope the FCC will reopen the whole matter for reconsideration.

Kenneth Cregar K3KBG
3411 Stoudt's Ferry Bridge Rd
Reading PA 19605

National NCX-1000 Transceiver

Transistorized transceiver (except for driver and final), runs 1000 watts, yet is just a bit larger than ordinary transceiver! Complete kilowatt ham station in one small, light unit. Tested by 73 staff and found to be a really great unit.

The world of transistors and ICs makes it possible to have a complete kilowatt *all* band ham station in one small unit! Not much larger than normal transceiver yets runs solid 1000 watts. Extremely sensitive, processed speech for maximum umph when wanted, everything you need in one little package. Only tubes are driver and final.

The NCX-1000 lists for $1100 and is an unusual bargain at that price. The 73 test unit, used a few days and under brand new factory warranty, is available to the first $700 check received.

LAPEL BADGES

Name and call identifies you at club meetings, hamfests, busted pot parties. Hand engraved by skilled New Hampshire craftsman with loving care. Only one lousy dollar. Send first name and call and buck to:

RADIO BOOKSHOP, Peterborough NH 03458

Desk Call Plate *only* $2.00!

Up to 20 letters on a desk plate, embossed white letters on walnut background; ebony stand. Looks great on rig with your name and call. Watch envy race through your neighborhood. Send along 20 well chosen letters (spaces count as letters too), include a nice fresh two dollar bill, and give us a strong hint on where to mail the exquisite piece of craftsmanship.

RADIO BOOKSHOP, Peterborough NH 03458

My low opinion of IL is colored by the personal blight of downgrading after more than a half-century of good behavior on the ham bands. It all seems so unnecessary. I would think that old experienced people could be let alone and not subjected to such indignities as have been dreamed up from time to time by the ARRL. I can't be mad at the FCC, who – I am sure – simply felt that Newington could hardly be wrong. As a matter of fact I recall that the FCC turned this thing down some years earlier on the basis that it would lead to an elite establishment with a supposedly democratic government put in the anomalous position of enforcing a caste system.

R. A. Hilferty W2HEY
Box 409
Miller Place, LI, NY 11764

I hope that someday this incentive licensing thing can be rehashed...Now I have a General license which restricts me to certain portions of the amateur bands ...and the ironic thing is that Extras seem to operate in the General portion of the band.

John Stagnaro W6MAB
2305 Panorama Dr.La Crescenta CA 91214

I don't have any idea how much influence you will be able to swing in your effort to convince FCC that this whole thing was ill-advised, but if I can help by sending you my opinions, then it is the least I can do. I am against IL, and would only be for a 20 wpm requirement if use of a typewriter were optional.

Bill Gulledge W9LWG
Rt 3 Box 56
Phillips WI 54555

Finally someone uses a magazine to get opinions on the IL program on a national scale. I hope that 60% of votes is not the losing percentage (see p. 9 QST Sep 1970).

Harris WB8BTV

It's not incentive licensing when the FCC narrows and removes frequencies so as to load the remaining spectrum with nets and phone patches. And cramming ARRL activities into the highly congested remaining portions of the bands is idiotic.

R. W. Daniels K0KYH
Rt 2 Box 212
Aitken MN 56431

IL was supposed to be a step above General; instead, the space between Novice and Extra was split in three rather than two. And the present General is not up to his predecessor, who knows half the Advanced test from his old General exam. Thus, either increase the exam requirements for Advanced or throw it out! Let those who know the code at high speed get credit for it, but let the chap who doesn't know it demonstrate some alternate ability. If the FCC insists on restricted privileges, how about power? New Generals to get 150W, maybe Advanced and Extras could get the full gallon.

Joel Look W1KCR
Box 25
Claremont NH 03743

Radio Interference Reduction

Some hams try to purchase new electric razors for neighbors in an attempt to reduce existing razor QRM. However, attempts I have made to find any razor that is treated to reduce QRM, have not been successful at dealers. Finally, I received a reply from a SEARS buyer who said that their 92737 razor (Austrian) claimed to be so treated. I had read many instruction sheets with new razors without seeing any such comment on other products.

I think that the magazines should be willing to mention this, and to list products that have reduced QRM.

Note Public Law 90-379, 90th Congress, which amends the Comm. Act of 1934, permitting FCC to regulate the interference potential of devices. QST published a request for letters to FCC suggesting items heading such regulation.

I think that amateurs should encourage FCC to bring out at least a general requirement that household appliances be treated for reduction of QRM, and especially that thermostats be treated to prevent "hanging" of the contacts in a sparking condition. Also, essentially all light switches could be so treated – which I understood was required in France 35 years ago. I encourage the magazines to stir up a little thought on the use of the Public Law to reduce QRM.

La Canada CA

Sparkling

Keep up the good work with 73 Magazine. You have a good following at KEYN. We have four active hams on the staff. Our News Director KØWTM has his two young sons licensed as Novices. I'm now working on the general manager and his oldest son and hope to get them tickets. The station supports the WØDKO repeater with tower space and power. You can imagine the response a CB organization receives when our program director (W5MGC) takes the call. Our weekend disc jockey and engineer WAØTHQ is a senior at Wichita North High School. Oh yes, we also operate a station WAØZZX on 2 meter FM from the KEYN studios.

Anyway we here at KEYN heavily support Amateur Radio and 73 Magazine. Each copy I receive from my new life subscription is well digested before I safely file it away.

Larry Waggoner WAØQPM
KEYN, 3357 W. Central
Wichita KS

Lackluster

I keep reading in the letters column the bouquets that come your way regarding the magazine. I started subscribing some time ago and thought the same way – even got the back issue Gunsmoke and enjoyed them all. However, in the last year or so, it seems to me that 73 has lost its sparkle and is becoming a lackluster publication. 'aybe it's me, maybe not. Anyway, it seems to be turning into a specialty-type magazine geared for VHF-Novice interests. Of course, maybe this is what you want.

I wonder how much the advertiser influences editorial policy? I have yet to see an article saying that a particular piece of equipment is a piece of junk. These "reviews" in all the magazines claim that anything is the biggest thing

RG 196 AU 50 ohm teflon coaxial cable. Outside diameter .080" RF loss .29 db per foot at 400 Mhz. Silver plated shielding and conductor. Used for internal chassis wiring, antenna coupling, RF coupling between stages, etc. Random langths from 35 foot to 150 foot. Colors: black, red, brown, blue, gray, orange. Regular price- 23¢ per foot. Our price 5¢ per foot $3.00 per 100 ft.
456 Khz ceramic filters type BF-455-A. These filters will help to sharpen the selectivity of most sets using 455 Khz IF's. Use across cathode bies resistor in place of e capacitor, or in transistorized sets, across the emitter bias resistor. Impedance is 20 ohms at 455Khz., DC resistance is infinite. Impedance increases rapidly as you leave 455 Khz. Plan your own LC filter circuits at very low cost.
10 for $1.00 25 for $2.00

TOROID POWER TRANSFORMERS

T-2 This toroid was designed for use in a hybrid F.M. mobile unit, using a single 8647 tube in the RF amp, for 30 watts output. Schematic included. 12 VDC pri. using 2N1554's or equivalent. Sec. #1 500 volts DC out at 70 watts. Sec. #2 -65 volts DC bias. Sec. #3 1.2 volts AC for filament of 8647 tube. Sec. #4 C/T feed back winding for 2N1554's. 1¾" thick. 2¾" dia. $2.95 ea. -2 for $5.00
T-3 Has a powdered iron core and is built like a TV fly back transformer. Operates at about 800 CPS. 12V DC Pri. using 2N442's or equivalent. DC output of V/DBLR 475 volts 90 watts. C/T feed back winding for 2N442's $2.95 ea. -2 for $5.00

since the ice cream cone. For instance, I had a Swan VHF antenna, made by the Stockton man, that flew apart in the wind, mainly because of insufficient hardware. I wrote something about it and sent it in – no response. Wrote another and sent it to QST – and got a nice letter from the technical consultant that they only checked the 2 meter, not the 6 meter.

I believe there is a little more than a year to go on my 73 subscription and I frankly don't intend to renew it for a lack of interest in the contents.

Paul Schuett WA6CPP

A lot can happen in a year

. . . Ken

Easter Island

On March 20, 1970, I was licensed to operate my amateur station from Easter Island with the call sign: CEØAE. I have been operating with this sign since May 20, and work all bands, CW and SSB. Only twice have I operated above 21,400 on the 15 meter band. My name is "Dave", my QSL Manager is WA3HUP, and my QSL card is red and white. I do NOT have an APO address. I have received fewer than one QSL card for every three contacts, and would appreciate more. My usual frequencies are: 28,550 – 21,360 – 14,332 – 7030 – 3530.

Fr. David L. Reddy, O. F. M.
Parroquia
Isla De Pascua, Chile

Flamboyant

In my opinion your increasingly flamboyant headlines lower the appearance and appeal of 73 to the level of cheap trash like CQ and PE, and waste space that could otherwise be devoted to several more pages of articles.

73 is not Movie Mirror or True Confessions. For examples of proper headlines for a technical magazine see July QST.

R. B. Kuehn WØHKF
St. Paul
MN

The Good . . .

A friend loaned me the June and July copies of 73 magazine. They're the greatest. I saw your notice about a bundle of back issues of 73 for $6.00. My check's enclosed. Hope I'm not too late.

I'm in a Code & Theory class. As soon as I get my Novice ticket, I'll subscribe to your fine magazine. Can't see how any amateur can be without it.

My sentiments are with your point of view on every issue in these two issues of 73. Keep up the good work.

Jim Edwards
Chillicothe OH

. . . and the Bad!

In your recent letter asking me to renew my subscription you said that you were worried that I would not renew my subscription. Well Gentlemen I would like to say that you had better start worrying for your publication has become sheer garbage in the past 9 months. If you want to sell your mag, you had better try the funny farm for they are the only people that might find your magazine of interest!

Lloyd Dolese Jr. WN5ZZF
220 E. Maple Ridge Dr.
Metaire LA

Mideast

Wayne's helping Hussein out was a true gesture of gentlemanliness in the true ham spirit. I guess you just have to remind some people that you are not a discriminating person. To me, Hussein is a person who has same common interest as myself, ham radio, and this ham fellowship (to me anyway) is not affected by either race, creed, color, religion or place of birth. As for those childish kids who say, "OK, now go to Israel or you're anti", let them go somewhere!

Wayne has befriended a great ham for all of us. May I remind some people that Hussein has understandable troubles of his own and he gets on the bands (like most of us, anyway) to relax and take it easy. You must forgive some of us, Hussein, for those pileups, but you're still a rare one for many of us. Take it easy and as long as you are a member of the fellowship of hamdom, I won't yell at you about the Mideast. My feelings remain much the same for Wayne. Keep up the good work. Times, they are a-changin'.

Chip Cohen WA1JHO

Ham Critic

It strikes me, Wayne, that the technical quality of the articles is slipping. "More Notes On Diode Stacks"" must have been written for the Novices or the XYLs. Maybe my interests just were not touched – we'll let it go at that.

Brown (W9HBF) must not have listened recently on CB; further, he should keep track of what hams do in emergency communications. I could have enjoyed the Sept. issue a lot more if this article had not been in there! QRP, yes – CB, no!

WB4ITN could have something real useful going with his file-box series if he handles it correctly, and produces some really handy gadgets for the shack.

One has to question the use of the word "waveguide" in KICLL's attenuator article. Two coffee cans soldered together will do the same job only it's called shielding!

There are a lot of pluses in the Sept. issue: W7PUG's CW ID Generator, WA2IKL's IC Testers, K6MVH's Antenna Separation, and Douglas's Relay, etc. The study guide material is always excellent. Too, WB6YVT's 2M Converter looks good.

It is noted that the number of advertisers seems to be picking up, Wayne. Anyway, I guess you know that I read "It" from cover-to-cover. Thanks.

73's Carl K2IA
10-16 Burbank Street
Fair Lawn NJ

In regard to the letter by Ernest Robarge, who says he would make a good ham except he can't pass the code exam, it really made me laugh. Over 600 hours of code and he still can't pass it. I took 16 hours for my Novice and passed with no trouble. So as far as code goes I'm okay but I can't get enough theory to pass the General. But I'm still going to keep on and not write to 73 to tell the world what a fool I am.

Bob Mackey WN9ERZ

Somebody's sure been writing letters over your signature. . . . Ken

Atlanta Repeater Problem

K6MVH's recent editorial on the Atlanta repeater was an accurate description of the situation as it now exists in that area. I lived in Atlanta for over five years and still maintain my "4" call because of frequent trips to the Atlanta area. The group which originally began construction of the Atlanta repeater consisted of serious amateurs with a desire of promoting the growth of FM activity. This group was gradually overtaken by a group of ex-Army MARS operators who, after a change in command of the MARS group, became dissatisfied with the Army MARS FM repeater program. This group then used its political and financial contacts to establish the Stone Mountain repeater. This group has never liked to have its inner circle questioned, even while affiliated with MARS.

There still remain a few stations who will work transient mobiles. However, the control station will not work anyone with what he calls a "Yankee Brogue," which includes anyone who does not come from the 4th call area. I have been called down by that station because he cannot understand anything but deep southern drawl!! On my last visit I made the statement on the repeater that the Atlanta area was getting a bad reputation in FM circles. This stirred up some comments, both pro and con. However, it did serve to wake up some of the operators in the Atlanta area, and, for several days every transient operator was worked by several stations. Thus, I hope that Ken's editorial did some good.

73 Reader Service Coupon

Now we don't say that every single reader must buy every last product advertised in 73. We believe that, but we don't say it. The very least every reader can do is to put on a show of interest in the products herein advertised. To make this a simple task, even for the laziest reader (now there is a contest for you!), we have cleverly arranged the advertising index to double as a readers service coupon. All you have to do is tear it out (or photocopy it) and send it in with the appropriate boxes marked. (We have a prize for the most boxes marked . . . a silent prayer of thanks from the publisher). We'll accept postcards, slips of paper, or almost anything else that lists the companies you want to hear from and your address.

No one likes to go into a store without buying something, right? It is the same with these information requests. You will be expected to buy something. Oh, it doesn't have to be a $50,000 antenna system, but it should be something modest . . . a transceiver . . . a linear . . . you know. We'll leave the decision up to you, knowing that we can trust you to do the right thing.

And we are definitely not saying that the use of this service coupon has any curative powers, but we cannot but notice that many readers report remarkable relief from simple backache, headaches, lumbago, and acid indigestion after sending in their coupon. Why take any chances?
